Q. Is there any possibility of combination engines? I was thinking in terms of two things. One where you might have a solid propellant and afterburn with liquids so to speak, or bypass your solid propellant and add ram air.

A. Yes. If you can find a way to use some of the oxygen from the air for certain applications we could cut out the amount of oxidizer we carry in the case and so increase specific impulse. One of the hard things to get is money to invest in the state of the art. Mostly you have to tie your funds to a specific job. Some of the biggest advances we've made is where we've put our own money into the state of the art work and where the services have also seen fit to put some money in with us.

Q. I'd like to talk about production costs. Does yōūr process engineering group—production engineering group—have more or less equal status with your design people when you get to production missiles?

A. Oh sure. One reason that we moved our whole solid production business up to Sacramento is that we have our production people up there, our research and development people, the whole works. When you start to do the development on a new job, the production people are right in there to start, so that the hardware the development people turn out is something we can use later on. If you don't do it that way, then you have a terrific transition period from the development stage to the production stage.

Q. Is extruding of solid propellants more efficient than casting?

A. Well, it all depends on what you want. If you're going to have high volume, and you don't have to have too high a performance you can extrude the thing cheaper than you can cast it. But the cost of extrusion equipment is very high, and when you want to change the size of your unit, then you've got to change your whole set-up. We think the casting is going to be the best overall, particularly if continuous casting can be perfected.

Q. Can we go underwater—your 155 knot torpedo, for example?

A. We're doing a lot of underwater work. We think there's a real future.

Q. In the case of a hydroduct or solid propellant isn't there a noise problem where the self noise would interfere with the sonar gear in the missile?

A. Well, it all depends on how you're going to use the solid propellant. If you're using the propellant for a direct drive you'll have one noise level. If you're using it to run through a turbine, to run a propeller you have another. One advantage solid propellants would have for torpedoes you'd have a longer storage life. Of course with torpedoes you have to have a number of them ready to go anytime you need them.

Q. Do you see any room for liquid propellant underwater?

A. Yes, sure. We've done considerable work on it.

Q. Do you think that the solid propellant underwater engine has more of a future?

A. We think so. Maybe we're wrong, but we think so. We've done some work on hydrogen peroxide; we've done a lot of work on solids; but we think there's a real future for solid propellants in torpedoes.

Q. How fast will tomorrow's underwater missile be?

A. We think we can top 300 knots in operational underwater missiles.★

No limit to solid rocket size . . .

We think we've fired the biggest yet.

. . . can build 300-knot underwater missile.

DON'T BE HALF MACHINED!

Get flight quality hardware right from the start. Components that may originally be good enough for a static test stand don't always measure up to subsequent flight quality standards.

Above is a typical example of flight quality being machined in from the start. You see a Diversey craftsmen taking frequent checks on a forward closure for a large solid propellant rocket case. You see him using the largest Monarch Tracer Lathe in the country. The customer who receives this component is getting his flight quality right from the start. Why not you?

HYDROSPINNING NOW AVAILABLE

Diversey announces the formation of a new Hydrospinning Division with the aquisition of 2 new Hydrospin machines. Now you can also bring your hydrospin problems to Diversey.

SMALL SOLID ROCKETS for Commercial Use

By G. E. Rice

Manager of Commercial JATO Sales
Aerojet-General Corporation

SMALL ROCKET engines for emergency standby use are being installed at a constantly increasing rate in business and airline aircraft. Aerojet-General's pioneering efforts in this field have been instrumental in providing power units with operational performance capabilities. Commercial application appears to offer the greatest immediate civil market.

Business aircraft use of rocket engine standby units has far surpassed use by airlines. The airlines made the first civilian standby application for high altitude operations. The emergency performance margin of solid rocket engines is recognized increasingly by owners of DC-3's *Lodestars, Convairs,* and converted B-25, B-26, PV-1 and PBY aircraft. These engines have been installed in DC-4 and DC-7 aircraft operated by some airlines. Installations for other types of aircraft are being developed.

Aside from very minor modifications required by standby use, the rocket engine currently used is the same 15KS-1000 smokeless JATO which has been widely used by the military as an assist takeoff unit. After satisfactorily passing through exhaustive vibration, temperature and pressure cycling and drop tests, it has received a CAA Engine Type Certificate.

This 15 second duration 1000-lb thrust solid rocket is the only rocket engine that has received certification. However, Aerojet has a smaller 15NS-250 solid rocket engine currently undergoing CAA certification tests. This smaller unit is designed for use on the lighter aircraft, and may be installed singly or in multiples on airplanes from cub-size through the light twin engine class. It is understood that some other manufacturers are giving consideration to CAA certification of solid rocket engines but this far nothing has been announced.

Standby rocket engines are used on civilian aircraft to meet the requirements of takeoff and approach climb with one engine inoperative and landing climb with all engines. Where takeoff runway limitations occur, they may also be used to shorten the required runway by increasing the acceleration

and the rate of climb for earlier clearance of runway obstacles.

They will also provide full thrust within a few tenths of a second to greatly increase the aircraft performance margins to meet any other short duration emergency requirement. Analysis has shown that they offer a potential for application to over 40 per cent of the situations which lead to takeoff, landing or in-flight accidents.

The 15KS-1000 AI rocket engine weighs 144 lbs. and the 15NS-250 unit will weigh about 42 lbs. The rocket engine weights reduce to 72 lbs. and 21 lbs. respectively when expended. Installed weights are about 175 lbs. for the larger engine and 50 lbs. for the smaller one.

An existing CAA interim policy permits an increase in the gross weight of transport category aircraft equal to the weight of the installed rocket engines in all cases where such weight increase will not exceed the structural gross weight limitation.

As an example, a typical DC-3 installation of two 15KS-1000-AI rocket engines weighs 350 lbs. In DC-3s licensed under transport category performance limitations, the gross weight may be increased by 350 lbs. with the rocket engines installed whenever the weight is limited only by CAB takeoff climb requirements.

A proposal for a new Special Civil Air Regulation is now under consideration by the CAB which would provide much greater weight credits and still result in higher emergency acceleration and climb margins. This proposal covers aircraft certificated under CAR 3, 4B, 4a(T), SR406, SR407, and the new turbine powered aircraft regulation. Early action is expected on this regulation and it should serve to greatly stimulate standby rocket engine installations in both airline and business aircraft.

The gross weights of multi-engine aircraft are generally limited by CAR requirements for climb with one engine inoperative. Under this condition, the maximum available thrust is required to maintain level flight.

Convair 240 equipped with 15KS-1000-AI standby motors mounted externally and internally.

The small remainder available for acceleration and climb is known as the "excess thrust." Since the thrust of one standby rocket engine may be equal to several times the normal "excess thrust" with one engine inoperative, the introduction of the rocket engine thrust will result in phenomenal increases in rates of climb or acceleration.

Limitations in the proposed CAR on the amount of standby thrust for which credit may be obtained preclude the possibility of creating a critical performance situation in an airplane equipped with standby rocket engines. Under the philosophy of the proposal, multiple sequenced units will be required to gain the highest weight increase. These units may be ignited simultaneously to produce very high rates of climb or acceleration to meet severe emergencies.

Standby rocket engines may be either submerged in the airframe or mounted externally. In high speed aircraft the submerged installation is generally preferred. However, measurable drag effect has not been found in multiple 15KS-1000-AI standby engines mounted under the center section of several types of low wing airplanes with speeds up to 365 mph. Design criteria for engineering new installations have been prepared and are CAA approved.

Indicative of standby rocket engine value are three otherwise marginal instances in South American high altitude airline operations. In each case a passenger-laden, four engine aircraft was in critical speed range with no opportunity to accelerate with normally available power. Standby thrust accelerated all three airplanes into speed ranges with comfortable safety margins.

Several manufacturers are now contemplating optional factory installations of standby rocket engines. It is believed that in the not too distant future it will be considered quite normal to incorporate such systems in the basic airframe concept, both as a safety factor and to broaden the operating flexibility of the airplane. ★

DC-3 is assisted in takeoff with 15KS-1000-AI standby rocket motor. This unit is the only rocket motor that has received CAA certification.

"AURORA," a recent expression from the brushes of Simpson-Middleman, a team of artists who find their subjects in the world of the natural sciences. "Aurora," they explain, "is a visual statement with equivocal overtones of dawn, the Aurora itself and a hint of a Chimera." Painting courtesy of John Heller Gallery, Inc.

You'll discover new horizons at Boeing

Through the years, the advanced work of Boeing engineers and scientists has opened new eras in civil and military aviation. A few of their pioneering accomplishments: the first 3-mile-a-minute transport, the world's first four-engine pressurized airliner, the first high-performance four-engine bomber—and the 707, America's first jet airliner. Boeing in addition has developed a defense weapon system spearheaded by the supersonic Bomarc IM-99 interceptor missile.

If new horizons interest you, you'll enjoy working at Boeing. For here you'll find engineering excitement in such advanced fields as electronic and inertial guidance, chemical fuel propulsion, guided missiles and supersonic flight of the future.

BOEING

Propulsion Engineering

By Alfred J. Zaehringer

MORE LOX FOR MISSILES: Air Products is working on two oxygen plants for the government. One is a 20 ton/day unit (cost is $\$1/2$ million), the other is a 5 ton/day unit ($100,000). ARDC has a new 150 ton/day unit installed at Edwards AFB, Calif. Tonnage LOX can now be produced for $5-15/ton.

MORE HELIUM, TOO, will be going into missiles for propellant pressurization, high pressure controls and actuators. By 1960, the missile industry will gulp down some 300 million cubic feet of the gas per year. In 1950, helium output was about 63 million cubic feet a year.

INDICATIVE OF AMERICAN POTASH & CHEMICAL CO.'s role in the missile market: formation of a chemical fuels section. The section will manage sales of boron and lithium chemicals for exotic fuels and ammonium and potassium perchlorate for solid propellants.

CHEAPER EXOTICS ARE ON THE WAY: Price of sodium borohydride—an intermediate for producing Olin Mathieson alkyl borane fuel—is to go down. Cost of OM's HEF-2 fuel was running $5,000/lb. but is expected to drop to about $4-10/lb. in full-scale production. The high energy fuel would enable the B-58, for example, to fly around the world without a refuel.

LATEST EXOTICS: the diammoniate of tetraborane, a stable $B_4H_{10} \cdot 2NH_3$, reported by the University of Michigan; this compound reacts with water to liberate hydrogen and looks interesting for underwater propulsion systems. Meanwhile at Iowa State College, a nitrile has been reacted with a boron hydride to give $B_{10}H_{12} \cdot 2MeCN$.

STATE OF THE ART of propulsion devices for space flight is "highly speculative" at the present time according to Rocketdyne's George Sutton. Liquid propellant rockets now seem our best bet. Atomic rockets might offer two to three times the specific impulse and other performance increases might come from successful storage of free radicals.

BIG BUGABOO IN ETHYLENE OXIDE systems—large amounts of coke in combustors and carbon in the exhaust. Aerojet, for example, gives ETO exhaust products as (all per cent by volume): hydrogen, 9.1; carbon monoxide, 46.6; methane, 38.4; ethane, 2.0; carbon, 3.9. ETO gives a $C^* = 3474$ ft/sec (chamber pressure of 750 psi and $L^* = 1000\text{-}2000$).

ON THE HORIZON: potential replacements for ammonium nitrate oxidants in solid propellants. Present AN catalysts do not give completely smokeless exhausts. Newer oxidants, soon to be attractively priced, will not require messy catalysts and promise greater stability and lower operating pressures.

THE SOLID PROPELLANT PEOPLE have a waste disposal problem, too. All spillage, waste and residue have to be carefully isolated and carried out to a dump for burning or detonation. As a result serious study is being given to "recycling" scrap propellant for use in a new batch.

THE SEPR FIRM has compared the use of hydrogen peroxide and nitric acid oxidant systems with kerosene fuel for use on manned aircraft. Nitric acid won on counts of high density, low cost and ease in handling. With the same fuel, peroxide systems were found to cost about ten times that of an acid system. The French rocket group ran acid in some 14,000 static tests and handled about 3000 metric tons without major trouble. At the same time, six severe accidents occurred in handling only 200 tons of peroxide.

ATOMIC COLEOPTER has been proposed by Helmut Zborowski, of the French BTZ firm. A nuclear rocket motor is suggested for boost while ramjets take over for sustaining cruise. A cylindrical rocket motor is used.

stepped-up interest:

Solid Fuel Missiles for the Army

By John I. Shafer
Jet Propulsion Laboratory
Huntsville, Alabama

THE ARMY has become increasingly interested in solid propellants in recent years because of the significant technical improvements and the distinct logistic advantages they offer for most of the Army's specific needs.

Early in 1945 research on solid propellants was focused on extending the operable temperature range. In time, substitution of a special elastomer or rubber for the asphalt fuel matrix revealed that cartridge charges would perform reliably even at —50° and 160°F. Furthermore, burning was reproducible at very low chamber pressures, so that the combustion chamber could be lightened and overall performance improved.

Ammonium perchlorate, too, had been substituted for potassium perchlorate in certain formulations. Thus, propellant flame temperature was decreased and propellant performance increased. Thrust and pressure were much less sensitive to changes in burning surface or nozzle throat area. Exhaust gases contained no smoke; however, in very humid atmospheres a fog was created in a rocket's wake.

The Ordnance Department, recognizing the need to extend development of the class of propellants and adapt them to production techniques and specific missile applications contracted with Thiokol Chemical Corp. late in 1946 for a broad development program. Facilities for this work were eventually set up at Redstone Arsenal; later a separate production facility with substantial capacity was also established at Longhorn Ordnance Works under Thiokol's management.

About this time, March 1947, JPL experiments were also made using a radically new charge geometry, the internal burning star.

With this design combustion chambers were so well insulated from the flame by the unburned propellant that chilled motors retained their surface frost, even after relatively long static test firings and despite flame temperatures in excess of 4000°F. As a result, rocket motor designs could be based on the room temperature strength of heat-treated alloys. Performance of solid propellant motors again increased significantly.

In separate tests they had also noted that their new rubber-base propellant could be cast into and the charge bonded to the combustion chamber itself. Adhesion occurred automatically during the charge solidification operation following casting.

With the adoption of the internal burning, case-bonded charge, additional benefits were realized:

1) Processing costs were reduced.

2) The charge was fully supported by the motor against pressure and acceleration forces throughout flight.

3) Performance was further improved by eliminating supplemental charge supports and through higher propellant loading density.

4) The relatively rigid propellant charge materially supported the chamber during transport and handling in the field.

Fundamental research was paying off with significant technical gains.

During November 1947 and April 1948, flight tests were made with a small research vehicle to evaluate the rubber-base propellant for large boosters. Accelerations in excess of 100 g demonstrated their applicability; despite a relatively heavy air frame, velocities were greater than 3500 feet per second. This motor, in a slightly shorter length, was pressed into service as the interim propulsion system for the Air Force guided missile *Falcon* through the cooperative efforts of Hughes Aircraft Co., JPL, Thiokol Chemical Corp. and the interested Armed Services.

Significant improvements in propellant and motor performance continue to materialize as a result of the collective, coordinated effort of all agencies working on solid propellants. Today there are alternate propellant formulations, both composite and double-base (nitrocellulose-nitroglycerin), that exhibit competitive performance in large and small motors, so that the country is not dependent on the rubber-perchlorate type exclusively.

As a result of the Army's long and active endeavor in the solid propellants field, many of its missiles are based on this form of propulsion.

Some of the newer systems acknowledge the increasing interest in solid propellants, like the *Nike Hercules*, which will in time replace *Nike Ajax* and will have a solid propellant sustainer as well as booster. Both *Lacrosse* and *Hawk* will have this type propulsion. Even the somewhat larger *Corporal* will eventually be replaced by the *Sergeant* which will be powered by a solid propellant motor.

In view of the fact that solid propellant missiles at the end of the war were unable to compete performance-wise with liquid systems such as the V-2, one might ask how they have succeeded in such a short time in closing the large gap. Many factors shortened the time schedule; the following undoubtedly contributed:

1) The solid propellant motor is inherently very simple. Once basic research had established fundamentally desirable propellant properties and motor design criteria as a firm foundation on which to build, progress was rapid. It might be said as a corollary that the motor's simplicity also permitted fundamental solutions to problems rather than temporary or patch-up solutions.

2) Interchange of information on problems and developments has been quite free in the entire solid propellant field and all agencies have profited enormously. Unfortunately, the

problem of "proprietary rights" has entered the field so that the interchange is now somewhat restrained, but it is hoped that this problem can be resolved soon. As early as 1946 the Solid Propellant Information Agency (SPIA), jointly sponsored by all services, was created to further this objective. Important annual symposia and a strong reliance on SPIA by all solid propellant personnel are tributes to its success.

3) Very close liaison by U.S. Army user agencies and the Ordnance Corps has repeatedly guided and reoriented the research and development agency with respect to Armed Forces problems and requirements.

4) The solid propellant industry appreciated its early performance deficiencies with respect to liquid propellant systems and therefore concentrated on first things first. It minimized any duplication of effort and avoided in most cases an examination of areas that might offer fringe benefits only.

In periodically evaluating solid and liquid propellant systems for new applications, the Army's special requirements must be kept in mind constantly. Basically it is concerned with tactical rather than strategic weapon systems. It therefore demands high flexibility and unusual mobility consistent with the PENTANA concept of tactics in which units disperse to avoid detection and destruction but converge to fight.

Tactical units must be small, independent battle groups capable of operating for extended periods at long distances from higher echelons. They must no longer be roadbound and tied to a ponderous logistic tail but must have improved cross-country mobility through the increased use of cargo carriers and air vehicles. Much of the supplies to and within the field army must be delivered by aircraft of the assault cargo and convertiplane type.

Unlike the Navy which carries its home with it, or the Air Force which returns home each night, the Army and its equipment must be able to survive and function miles from civilization in an environment of extreme heat, cold, humidity, salt spray, fungus, sand or mud. In the chain of supply from factory to depot to launcher, experience had shown that even before PENTANA, the closer one came to the launcher, the more important it became to minimize manpower, equipment and problems of handling and maintenance. PENTANA now merely serves to emphasize this.

The fundamental objective of the missile system itself is to detonate a warhead on a given target at a designated time with a specified accuracy. Delays in launching can frequently be as serious as inadequate accuracy or range. The threat of counter-fire, too, prompts one to "shoot and scoot" when possible.

Missile ruggedness and reliability will also be of prime importance. Units must be capable of withstanding "humping" loads from railroads, vibration from aircraft, the jolting from trucks on rough terrain, as well as frequent loadings and unloadings, yet maintain a high degree of reliability.

The simpler the system, and the less it demands manpower having special skills or non-standard equipment requiring special maintenance, the more desirable it will be.

Solid propellant proponents are quick to point out that their inherently simple propulsion system meets most of these requirements quite well. With a pre-packaged motor, operations in support of the propulsion system are negligible. The need for a large number of nonstandard trucks, equipment and personnel with special skills, normally required for fueling in the field, is obviated. In addition, missiles stored with pre-packaged propellants are available on a moment's notice, a factor particularly important for anti-aircraft missions.

They point out, too, that the reliability of their propulsion systems is particularly noteworthy. Motors now in production, that have firing failures, ignition malfunctions, improper thrust program and motor failures constitute a very small fraction of the total number of high performance booster or guided missile propulsion systems used. The failure rate is less than one-quarter that of comparable liquid systems. Alternately, the amount of development time and money needed to achieve a given degree of reliability would be less for the simpler solid system.

Motor ruggedness in the field and transportability are enhanced materially by the stiffening action of the relatively rigid solid propellant charge, particularly when case-bonded. With the trend toward higher-performance missiles and lighter motor structure, this factor assumes more importance.

Of interest to programs developing large motors is the fact that solid propellant designs may be evaluated in small inexpensive motors and then scaled directly to large motors, which will have identical performance (except, of course, for those characteristics that should change with scale). Motors differing in weight by a factor of more than one hundred have confirmed this early proposition. Of interest, too, is the fact that no one has yet built a solid propellant motor too large to work successfully.

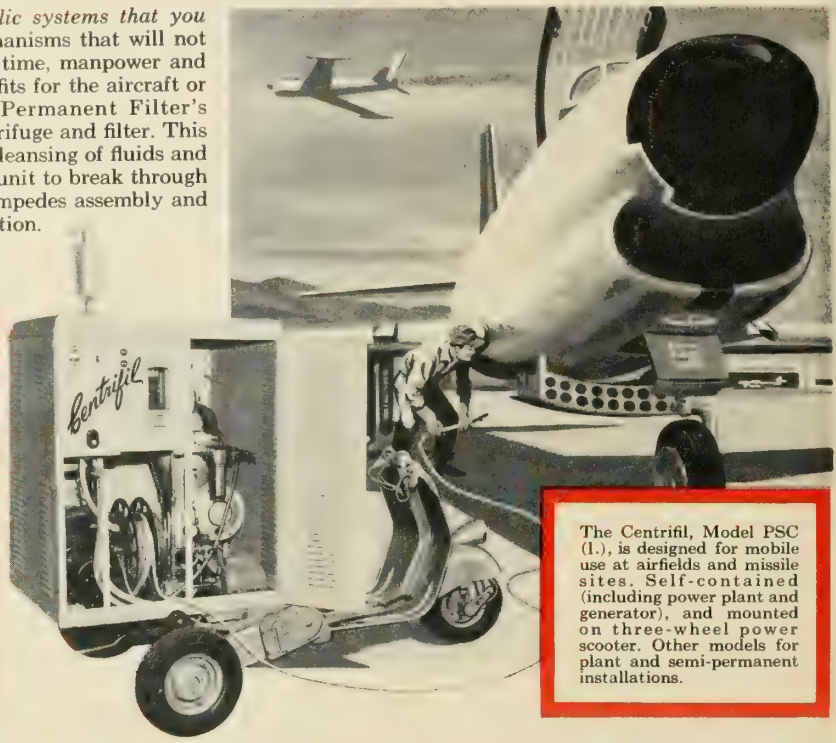
In large ballistic missiles the substitution of solid propellants for liquids in the tanks would eliminate the guidance complexity normally associated with fuel sloshing in flight. So, too, problems normally associated with control of liquid propellant mixture ratio are non-existent; in solid propellants the ratio is "frozen" at the factory. Finally, excessive axial accelerations that could penalize guidance accuracy can, in most cases, be avoided automatically by selecting an appropriate charge design; no separate mechanical devices would be necessary.

The report that the cost of solid propellants after loading in a motor exceeds that for liquid propellants is, in most cases, true. However, the cost of the complete propulsion system when metal parts are taken into account appears to be lower for solids because of their extreme simplicity. In the ultimate comparison, however, the relative propulsion costs will probably be determined by the extent that each influences the complexity and cost of their guidance systems.

It is important to maintain a proper perspective and recognize that solid propellant systems also have their problems and disadvantages. Most of these are concerned primarily with surface-to-surface ballistic missiles and the effects of propulsion characteristics on guidance.

The thrust level of most solid propellant motors changes much more with a change in temperature than liquid systems. This large temperature sensitivity increases complexity in guidance parameter setting (to admit temperature data) and increases variability or complexity of the flight computer markedly. These complications in guidance can be eliminated by temperature-conditioning the motor prior to its use.

A satisfactory method of varying the missile range precisely has yet to be established for solid propellant motors. Methods of cancelling or terminating thrust, comparable to propellant valve closure on a liquid system, appear to be very promising.



In some instances solid propellant motors exhibit irregular pressure fluctuations and motor vibrations typical of combustion instability. Guidance components then become damaged or degraded in accuracy. Fortunately, several promising cures have been devised to eliminate instability if encountered.

Finally, in the event that liquid rocket investigators succeeded in overcoming the problems in pre-packaged liquid systems without a serious penalty in weight and size, much of the logistic advantage that solid propellants now possess would be nullified. A second look would then be warranted. ★

For the first time...the industry's greatest need...100% clean hydraulic systems with CENTRIFIL

by PERMANENT FILTER

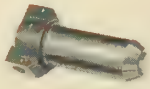
Hydraulic fluid and hydraulic systems that you can trust, delicate servomechanisms that will not malfunction, new savings in time, manpower and money . . . these are the benefits for the aircraft or missile facility that uses Permanent Filter's Centrifil, a combination centrifuge and filter. This entirely new concept in the cleansing of fluids and systems is the first practical unit to break through the "dirty oil" barrier that impedes assembly and testing, and endangers operation.

Flow capacity.....1 GPM
Max. oper. pressure..100 psi
Filters
1 Permanent Filter 40-micron
2 Permanent Filters 2-micron
Centrifuge bowl speed
7200 RPM
Centrifuge G's effect
60,000 G's
Filter cleaning (avg.)..50 hrs.
Centrifuge cleaning (avg).
100 hrs.
Models of greater flow capacity available

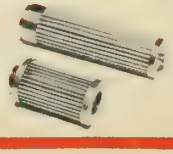
The Centrifil, Model PSC (l.), is designed for mobile use at airfields and missile sites. Self-contained (including power plant and generator), and mounted on three-wheel power scooter. Other models for plant and semi-permanent installations.

Don't purge systems—"CENTRIFIL" them!

A year of field-testing at aircraft and missile facilities has proved that "Centrifilling" actually removes 100% of all metallic and non-metallic contaminant particles over 2 microns in size from hydraulic fluid and systems. New fluid is invariably contaminated on delivery; delicate valves and pumps, unavoidably contaminated during assembly and operation, are safely, completely, and automatically cleansed when both the new fluid and the system are Centrifilled instead of purged in the ordinary way.



THE CENTRIFIL IS NOW READY



Permanent Filter's new Centrifil is now in production and is available for 45-day delivery. For more detailed information on this answer to the industry's greatest need, write, wire, or telephone Permanent Filter Corporation.

PERMANENT FILTER CORPORATION

1800 West Washington, Los Angeles, California, Telephone REpublic 1-7386

Heart of the Centrifil is Permanent Filter's Sintered Bronze Filter element, available in 400 standard types to meet 2-micron to 40-micron specifications.

Newest members of the family of Permanent Filter's fine filter elements are the new, improved, rigid mesh Dutch twill weave, stainless steel screen filters. Write for specifications. Available for immediate delivery.

Circle No. 27 on Subscriber Service Card.

Solid Propellant Rocket Testing

Accuracy is a must . . . so is quality . . . because the goal is perfection . . .

By H. E. Westgate

Grand Central Rocket Co.

ALL OF GRAND CENTRAL'S activities on solid propellants are vital and interesting but the testing phase is by far the most dramatic.

The scurry of activity by the various rocket technicians at a test site, their final withdrawal to the shelter of the operations bunker, the expectant silence of the final pre-firing phase culminated by the countdown: "5-4-3-2-1 fire"—these are the prelude to the roar and shaft of flame as the rocket responds to the signal from the firing bunker.

Technical organization for the test involves the Chief Test Engineer, his staff and three subdivisions or groups: the test mechanics group, the electronics instrumentation group and the data reduction group.

The rocket engines to be tested are of three basic kinds: the small research units supplied by the research department in order to determine the feasibility of certain rocket propellants or fuels; the larger experimental rockets designed by the Engineering Division for full-scale testing, and finally the well-established production units fired as part of the continuing check on the quality of production rockets.

Temperature Conditioning

If the rocket is of a type that will eventually be fired in the low temperatures of high altitudes or arctic conditions, the test firing may require a pre-firing conditioning or "soaking" at the extremely low temperatures to be encountered. Or, if the rocket is to be fired later under conditions of extreme aerodynamic heating or after being stored under conditions of tropical heat, a pre-firing conditioning at elevated temperatures may be in order.

In either case the mechanics will follow the test request and place the rocket in the proper hot or cold box or pit for the required number of hours prior to firing. At present Grand Central has 19 such conditioning chambers ranging in size from 2 to 20 feet in length.

Instrument Calibration

Coincidental with the final phases of the temperature conditioning of the engine, the preparation of the proper instrumentation for determining the rocket chamber pressure and gross thrust are readied.

Electrical calibrations alone suffice for some of the routine tests and are made with special electrical checking units. However, for many of the more precise tests the pressure pickups, which are installed directly on taps in the engine head and nozzle, are also hydraulically calibrated. This calibration involves the filling of each pickup with oil and pumping it up to exact pressure levels in a series of incremental steps.

When a rocket is expected to have a peak chamber pressure of three thousand pounds per square inch, the pressure pickup or transducer may be pumped up to one, two, three, four and five thousand pounds per square inch. Its electrical output is recorded at each one of these levels.

Later when the engine is fired these calibration points serve to fix with extreme exactitude the various points on the resulting pressure-time and thrust-time data. For even more critical testing, the same procedure is also repeated immediately following the test firing.

This later calibration serves to confirm the earlier calibration and to show with certainty whether or not any small change has occurred in the calibration of the entire system during the firing phase. Such double-checking is expensive and time consuming, however, and is reserved for the more critical tests.

Mechanical Preparations

While the electronic group is busy with the pre-firing calibrations, the

mechanical group is busy, preparing all the mechanical items necessary for a successful test. Among these are the nozzle, the head cap and the handling and mounting fixtures. The nozzles and head caps are generally not attached to the rocket until after engine conditioning since it is safer, especially at elevated temperatures, to perform the conditioning with the nozzles and head caps removed. In this state any accidental ignition would produce only a static fire since the engine could not develop appreciable thrust with both ends open.

When the allotted time for conditioning has elapsed the engine is removed from the conditioning box and readied for firing. At this point exact timing of the work counts and advance preparation and smooth teamwork pay off. The nozzle and head cap are first attached to the engine case and then the final attachment hardware are clamped on. The rocket is then transported quickly to the proper firing bay.

Installation of Engine in Firing Bay

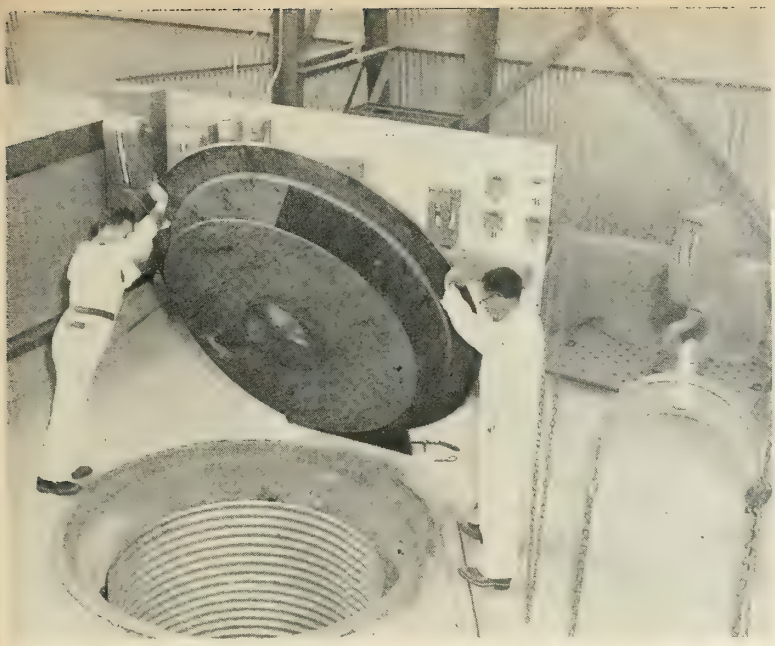
To expedite this series of steps, the conditioning areas, assembly area and the firing bays are located as close together as permitted by safety considerations. Six large firing bays are currently available at Grand Central's Redlands test site. All bays are of the type which secure the rocket engines in a horizontal position. This type has been found to be most convenient and minimizes the requirement for overhead handling equipment. All of the bays are equipped with heavy structural rails imbedded in thick reinforced concrete floors. These rails provide a strong anchor for the engine test stands.

The test stands are cradle-like structures which serve primarily to support and anchor down the rockets during the test firings. Some are merely used to support and hold down the motors. Others allow the motor to shift slightly forward when firing and so exert the firing thrust on measuring instruments. These in turn relay this information electronically to the instrument bunker.

Engines to be operated under specific high or low temperatures have to be capable of properly igniting under those conditions. As soon as a rocket is removed from a conditioning box its temperature naturally starts to return to the temperature of the existing surroundings. It is therefore necessary that the engine be fired as quickly as possible after its removal from the conditioning box if the required high or low temperature firing is to be a valid test.

The mechanical operations of properly installing a rocket in a complex firing stand may, by virtue of the existence of special mechanical features, require upwards of a hundred or more bolts in this final assembly. Likewise, a complete complement of electrical instrumentation to adequately determine chamber pressures, case temperatures and strains along with the thrust, may involve the last minute installation and electrical hook-up of as many as thirty or more electrical pickups and gages. These last-minute electrical and mechanical operations must therefore be performed under stringent time limitations which necessitate precise and efficient operation.

In some cases the speed element can be successfully slowed down by constructing a hot or cold conditioning box right in the firing bay surrounding the engine itself. This saves last-minute time but in general adds so much complexity to the test that this method is not as widely employed as might be expected.



Firing Instrumentation

Solid propellant engines may, depending on their size and grain configuration, burn anywhere from a fraction of a second to several minutes. In either case precise recording of the electric signals coming into the instrument room from the various instruments on the rocket is essential. These signals, when interpreted later, give the detailed technical picture of the firing. Hence there is a need for the fastest and most accurate recording devices.

Firing test data at Grand Central is generally recorded on long rolls of light-sensitive paper, the data being traced on the paper during the firing by banks of accurate, light-beam galvanometers. An eight to ten foot strip of paper 5 to 12 inches wide, all filled with a seemingly meaningless series of curved, wiggled, interrupted and otherwise deflected galvanometer traces may constitute the entire data from a firing which may last less than a second but, which may cost hundreds or thousands of dollars in materials and man-

Latest addition to Grand Central's facilities—three test bays for static firing small and medium-sized solid-propellant rocket motors.

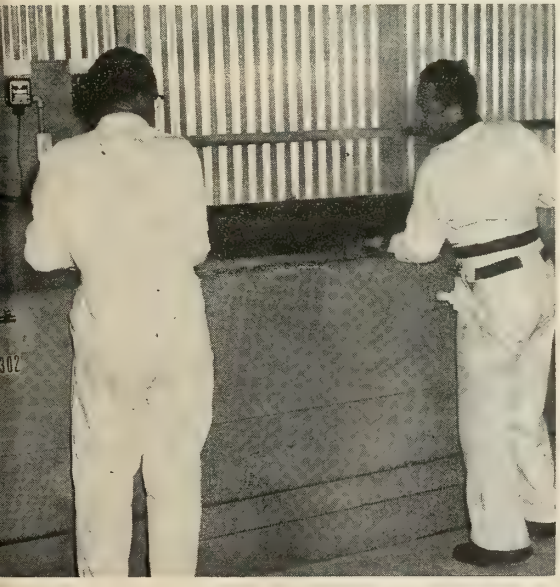
Attendants remove the lid from a large vertical pit-oven preparatory to curing operation.

hours of testing time.

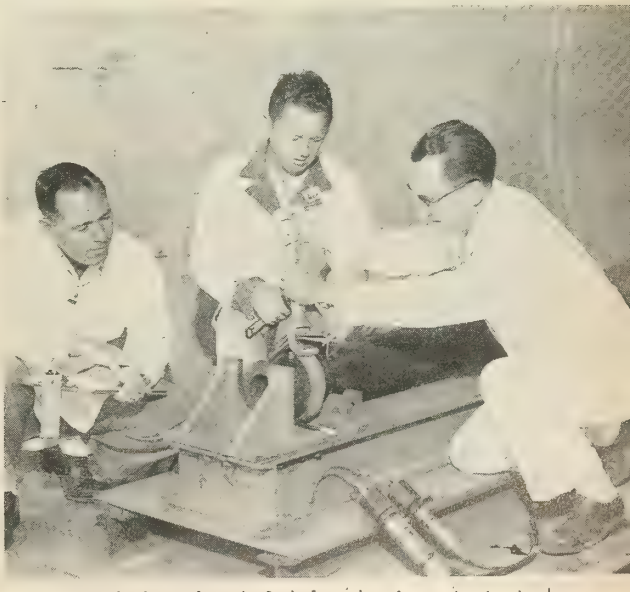
For tests of longer duration, the results of a single test may cover several hundred feet of this same paper. From the complexity of the lines and the length of the paper the subsequent job of data reduction can be readily appreciated. In most cases the roll or rolls, known as "the record" generally represent about 80 per cent of the data from a typical test firing.

Additional data is obtained visually by direct viewing, regular movies, high-speed movies or closed-circuit television. Additional audio information may be obtained directly by listening or by a more accurate microphone-tape recorder combination.

Grand Central has just finished installing at the Redlands test area a completely new automatic fire control console and associated racks of the necessary power supplies, amplifiers, monitors, and recorders. A wide variety of both D.C. and carrier amplifier recording channels are provided. By utilizing a system of switchboard plugs any combination of amplifiers and recorders may be plugged into lines extending to any of the six firing bays.

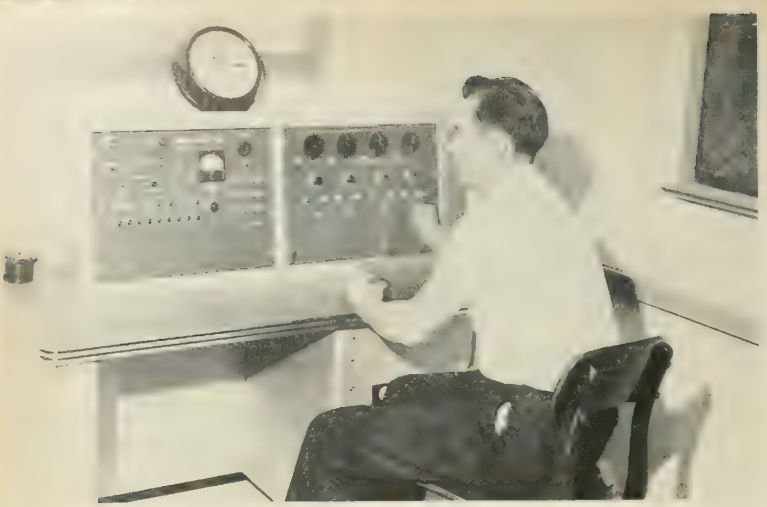


Firing



When the engine has been finally installed in the firing bay and all the instruments have been calibrated and attached to the motor, the engineers make their final checks and the time comes for the last minute operations. The test safety man checks the firing area and withdraws, progressively arming various key points of the firing lines as he leaves.

The safety man also brings the connecting safety "jumper" which is the final electrical link to complete the current flow between the firing console and the igniter. This jumper, which he carries at all times when working with a rocket in the bays, is his assurance that no one can fire the rocket before he and his men are safely in the observation bunker.



This jumper is now inserted in its proper socket in the firing console. When the instrumentation technicians are sure that all their recording gear is ready, they switch on the firing system, thus arming the firing console.

The firing operator then pushes the firing button. From here on the operation is entirely automatic and thus eliminates the possibility of any last minute errors of the test personnel. The firing console starts the electronic five minute countdown. Safety gate locks are monitored, and if any are left open or are later opened, the console will "kill" the firing. When the

LEFT—Test mechanics lowering a motor into a conditioning box. RIGHT—Final checking of nozzle fit before clamping motor to stand.

A portion of the instrumentation room which houses the power supplies, monitors, amplifiers., recorders, and switchboard panels for instantaneous channeling and recording data.

unit reaches the X-minus-thirty-second point the count-down delays begin to turn on cameras, recorders and other testing devices.

The electronic voice recorder drones out the verbal portion of the countdown in perfect synchronism with the timing unit. When it calls "Fire!" the rocket engine igniter is fired and the rocket engine surges to life. After the firing is over there is a brief wait which is terminated by the familiar all clear signal.

Post-Firing Procedure

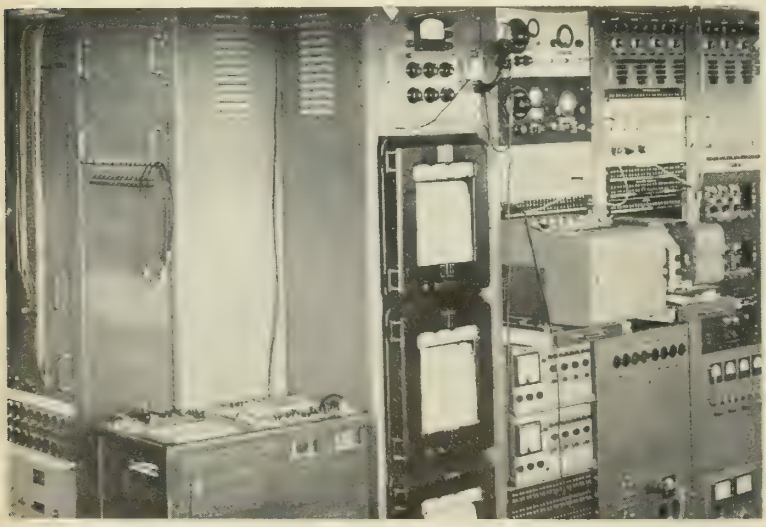
Following the all-clear signal the test mechanics start to dismantle the mechanical set-up and the electronics group unloads all the recorders and cameras and process the film and paper. The engine itself then comes in for some further study.

Auto accident analysts and air crash investigators have nothing on rocket development engineers when it comes to the analysis of charred engine parts, or in cases where there is an engine malfunction during testing.

The spent shell of a burned-out or fractured rocket engine may seem a worthless item. Actually the reverse is true. A normally spent rocket test engine is always carefully handled and precisely weighed to determine the degree of completeness with which the propellant grains burned. The nozzle is inspected for flame erosion, residues and high temperature effects. The final nozzle orifice size is recorded by micrometer readings or micro-projector diagrams.

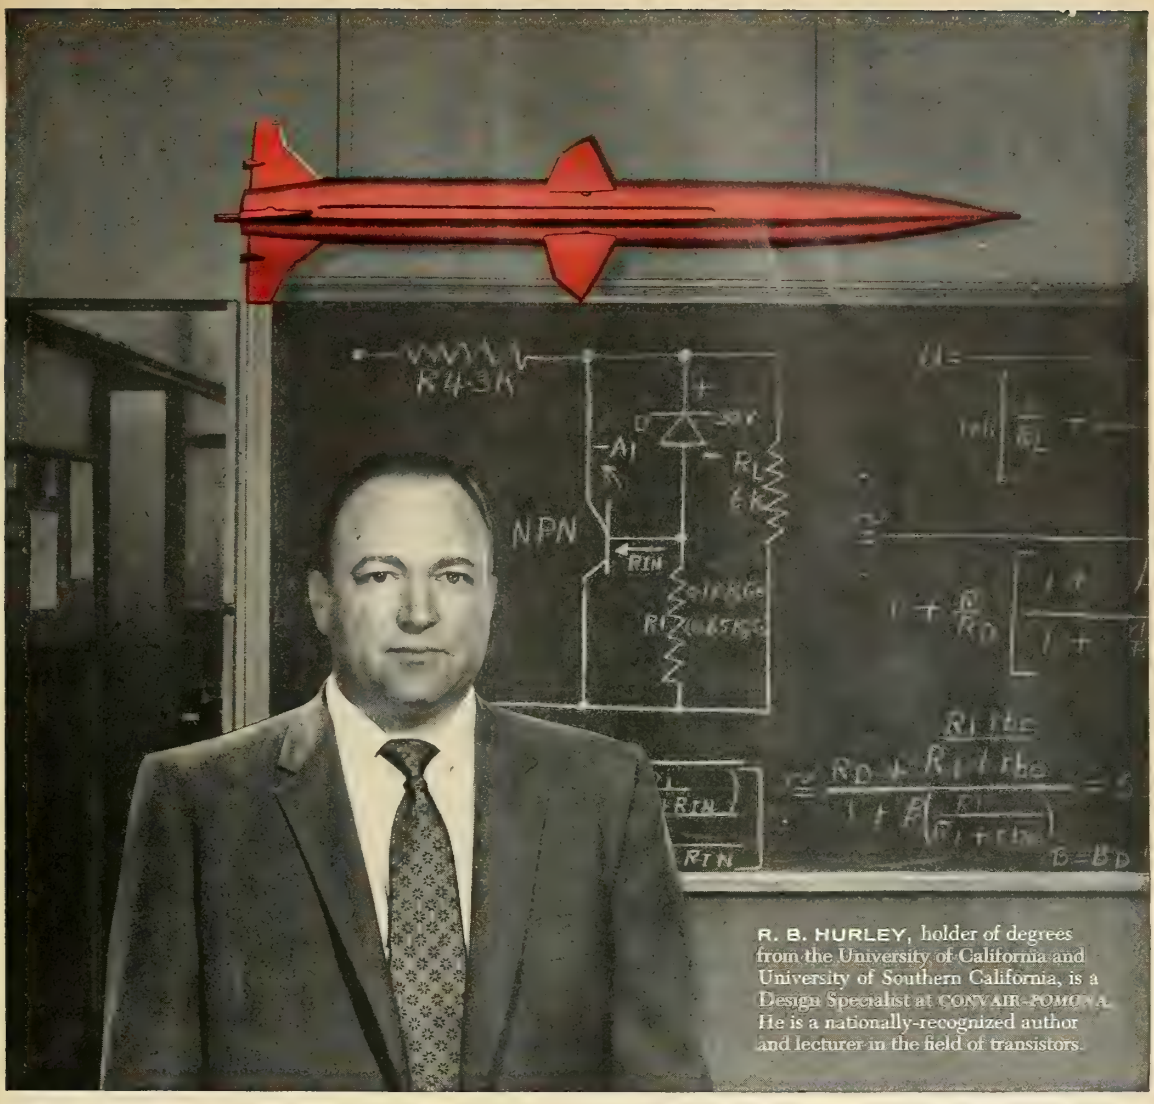
In the case of a malfunction, the analysis is even more thorough. This is generally true for two reasons. If the engine's performance was unique, unusual or just plain undesirable it is vital that the results be sifted to determine the exact causes of the particular malfunction.

Depending on the violence of the malfunction, it is possible that important instruments may have separated from the engine at the moment when the most enlightening data was being obtained. In the case of total failure the fragments of the rocket chamber and nozzle are methodically collected and fitted together to try to determine whether the failure was due to heat, pressure, imperfect parts or other causes. Often a sharp or dull-edged fragment, a tiny scorched piece of the case or a battered nozzle will give the clue as to what corrective engineering has to be undertaken.



When all the data from the recorders, cameras, observers and inspectors has been collected and the initial photo-processing, logging, marking and other basic operations have been completed, the combined and somewhat heterogeneous collection of information is ready to leave the test site and forwarded to the data reduction group.

Data Reduction



The tools employed by data reduction computers are primarily translucent "light-tables" (for properly inspecting the test records), scales, planimeters, sliderules and conventional calculating machines. The test data is thoroughly analyzed with these tools by converting the traces on the record rolls to typed data and charts which give engine burning time and thrust, combustion chamber pressure and wall stresses, nozzle temperatures, propellant specific impulse and other useful engineering information.

The New Remote Test Site

To meet the continual need for testing very large solid propellant rocket engines, Grand Central has set up a large motor test facility in an 1800 acre portion of an 8000 acre isolated mountainous area near Beaumont, Calif. Instrumentation vans have been obtained and are being equipped to provide mobile instrumentation facilities for this new Beaumont area. One large firing bay is already in use in the new test area and other bays are under construction in line with the need for continued and expanded work in the field of solid propellant missile development. ★

Grand Central's new fully automatic firing console. The panel includes the rocket motor operating controls, count-down lights, and camera and recorder time-setting controls.

R. B. HURLEY, holder of degrees from the University of California and University of Southern California, is a Design Specialist at CONVAIR-*POMONA*. He is a nationally-recognized author and lecturer in the field of transistors.

"Engineers—here's how we're taking part in the electronics revolution toward solid state devices"

"Here at CONVAIR-*POMONA*, we are constantly studying ways to apply the new miniature solid state electronic devices: the diode, rectifier and transistor. So new is this semiconductor infant, and so vast its future—both for the military and industry—that our teams of electronics engineers actually 'go to school' under some of the foremost experts in the field.

"As the *first* fully-integrated missile plant in the U.S., CONVAIR-*POMONA* designs and builds the Navy's TERRIER supersonic missile. And, realizing the potential value of solid state devices in meeting the critical requirements of such airborne missiles, we initiated a 'transistor program' early in 1953. This program has multiplied many times to become one of the most important in the industry.

"You, as an engineer, can appreciate the tremendous expansion that will come in the application of solid state electronic devices in the next few years. And you can readily understand the advantages of studying and working with these devices, guided by the advanced thinking you will find at CONVAIR-*POMONA*.

"You'll like the atmosphere here, where you see and feel accomplishment. And you will enjoy living in Southern California's beautiful Pomona valley. For greater career opportunity—*for your future's sake*—send for more information about CONVAIR-*POMONA today!* Write to: Engineering Personnel, Dept. 3-M

Swing to Solid Propellants

gaining momentum in missile planning

By John Wilson

Atlantic Research Corp.

CONTROVERSY BETWEEN liquid and solid propellant engineers over the relative merits of their propulsion system seldom leads to an impartial analysis of exactly where the two types stand in the current state of the art. A comparison of the present status and possible future status of the two systems is needed. It is needed not only by military planners, but by rocket and missile engineers who need to know the probabilities and the possibilities of development. The missile propulsion systems now in the dream-and-scheme stage can then take shape around the anticipated propellant developments.

Transportation planners are also interested in future propulsion possibilities for missiles. The big question mark here—how soon may we start using missiles for passengers, mail and freight deliveries? Nonmilitary uses of rocket power in the past have been limited largely to aircraft-assisted-take-off units—JATO bottles.

Planners now count on rocket power for routine transportation possibly within the next quarter of a century. In order that this go beyond the Buck Rogers day dreaming stage, costs must be drastically reduced to compete with air rates. Big technical problem to be solved is bringing the missile down safely, and exactly where you want it.

Current Status

Evaluation of the liquid versus solid propellant systems currently in operation must consider other types of propulsion now being used.

Turbojet applications, although limited because of altitude and subsonic speeds, power the *Petrol, Matador, Regulus,* and *Snark* missiles. Ramjets, operating from subsonic to Mach 5 or better at altitudes up to 100,000 feet, propel the *Bomarc, Talos, Navaho,* and *Triton.* The turbojet *Snark* and ramjet *Navaho* both have 5,000-mile range, but certainly neither should be compared to the liquid-propelled ICBM *Titan* and *Atlas.*

Ramjet and turbojet powerplants will continue to be used for manned and low-speed, low-altitude missiles, filling both military and civilian needs. It is in the long-range, high-speed missile field that liquid-propellant or solid-propellant systems will be called to supply the needed power for the immediate future.

The liquid propelled missiles are the most glamorous and consume the major part of missile funds. In contrast, there are a greater number of solid propellant missiles. Most are of small size for tactical missions.

This decided movement toward using solid propellants for a greater number of missile systems stems primarily from the difficulties involved in handling liquid propellants.

Advantages and disadvantages of liquid propellants are familiar to all missile men, and are quickly recited. Specific impulse is now up to 25% greater than for solid propellants. The operation pressure can be low, heat transfer can be regulated, and the rate and richness of the fuel oxidizer ratio can be regulated. However, it is in this separate handling of fuel and oxidizer that liquid propellants cause the most grief.

In the liquid propelled rocket plumbing becomes an outstanding and overwhelming engineering problem.

Solid propellants, with a lower specific impulse and presently lacking the control features which liquid propellants possess, has, in its ease of handling, a big lever with which to topple liquid propellants from their historically predominent position.

Missile work gets its big impetus from the military planners, and what the military decides is by and large the direction missile development is going to take. Defense appropriations pay for present missile research and development and any peaceful applications must involve as few modifications as possible. Aside from defense allocations there isn't enough available money for fruitful peaceful missile development.

Liquid Propellant Missiles

First consideration will be given to the liquid propellant missiles, which, in addition to their glamour value, have involved multi-billion dollar expenditures. The known missiles in this category are: *Rascal, Corporal, Nike Ajax, Titan, Bomarc, Jupiter, Redstone, Thor* and *Atlas.*

The Air Force intercontinental ballistic missiles, *Atlas* and *Titan* and the intermediate range ballistic missile, *Thor,* are liquid propelled. The Army has *Redstone* and *Jupiter,* although prospects of the *Jupiter* is clouded since Secretary of Defense Wilson gave the longer-range ballistic missiles to the Air Force. It is felt that the story is not yet completely told; and although the *Jupiter* missile is within the range stipulated, work continues. The mass-produced *Nike-Ajax* is the missile that the Army has deployed for defense all over the world. It is, by far, the most operational missile today.

Liquid propellant missiles owe much to the success achieved by the German scientists of Peenemunde during World War II. Many refinements have been made since and a lot of perplexing problems have been answered. Essentially the advances made in American liquid propulsion systems are not far removed from the German technology. Many engineers feel these same German missile men have been allowed to dominate the liquid propellant thinking.

As is repeatedly pointed out, it was solid propellants that got a head start, beginning with the Chinese rockets of the 13th century. Liquid propellants have had the longest record of concentrated development activity. Goddard's first experiments with liquid propellants began in 1921; his first liquid-propellant vehicle was launched in 1926.

Before World War II, major rocket development effort was concentrated in Germany, predominately in the liquid propellant field. Thus, liquid propellants have a continuous 35-year development history. Solid propellants had their first serious start during the last war but major effort has come only since the war. At most, solid propellants have a 15-year history of concentrated development.

In the meantime liquid propellant men are striving for plumbing simplicity. A benefit of this simplification would be the successful design of a small diameter liquid propellant missile. The best prospect today is the Naval Ordnance Test Station's 5-inch liquid-bipropellant aircraft rocket (LAR). Although this missile is unguided, the propulsion system, if successful in operation, could be applied to smaller tactical guided missiles.

Development of a monopropellant that could be handled as safely as aircraft fuel would give ease of handling both in servicing the weapon and in design of the missile system. Development of a liquid monopropellant presents many of the problems of a solid propellant, which is also a "monopropellant".

Swing Toward Solids

The listing of solid propellant missiles is more extensive and diversified. It includes the most outstanding operational or near operational: *Gimlet, Mighty Mouse, Zuni, Falcon, Sidewinder, Sparrow, Bull Pup, Hawk, Tartar, Terrier, Dart, Honest John, Little John, Sergeant, Lacrosse,* and *Polaris.*

The greater number of missiles, when compared with the liquid propellant list is immediately evident; not that either list claims to be exhaustive. Evident also, of course, is the size range, from the 2-inch *Gimlet* and 2.75-inch *Mighty Mouse* to the 30-inch *Honest John.*

Key entry among the solid propellants is the navy's intermediate range missile *Polaris.* Until it was decided to develop *Polaris* as a solid propellant missile, the down-to-earth thinking on large missiles was in liquid propellants. The barrier to large solid propellant missiles has apparently been breached.

In view of other shipboard missiles, either solid propellant or jet propelled, such as *Terrier, Regulus, Sidewinder,* the Navy's decision on *Polaris* was to be expected. Considering the difficulties present in carrying aircraft fuels aboard ship, there is little chance the Navy will involve itself with difficult-to-handle liquid propellants.

H. S. Seifert in an article on the development of missile propulsion for the last 25 years in "Jet Propulsion," November 1955, forecast the *Polaris* decision.

"Liquid rockets have held the lead as motive power for large-scale, long-range applications, but even here new developments in solid rockets indicate that this supremacy may be challenged."

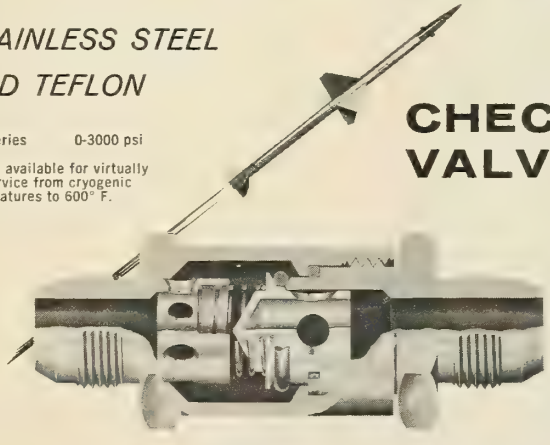
It would be premature to say that the supremacy of liquid propellant propulsion systems is challenged. It is evident that for large-scale, long-range, high-speed applications, movement is under way to break the monopoly of liquid propellants. Messrs. Stehling and Foster (m/r, Oct. 56, p. 58) proposed a rocket vehicle for a flight to the moon utilizing a solid propellant propulsion system. Considering the practically religious adherence to liquid propellants for this chore in the past, this would almost constitute a major breakthrough.

An outstanding example of solid propellants leading over liquid propellants is research rockets. Ease of development and handling are mandatory for research rockets. The only liquid propellant research rocket is the *Aerobee,* and *Aerobee-Hi.* The solid propellant research rockets now in use are: *Arcon, Asp, Deacon, Cajun, Dan, Iris, Rockaire, Rockoon, Terrapin,* and *Wasp.*

Synthesizing of the composite solid propellants has spearheaded the drive into the longer-range high-speed field. A new development in solid propellants was needed if they were to keep pace with modern needs.

The prevailing philosophy of World War II and immediately thereafter was to use large quantities of relatively short-range missiles to insure a reasonable kill probability. This is the barrage or saturation approach. Today, however, reliance is more and more being placed on a very few units of long range and high accuracy. We might call this the pin-point approach.

Solid propellant internal-burning grains were ideally suited for saturation tactics but they find considerable difficulty in meeting the new demands made upon them. There is an urgent demand for an end-burning grain which will answer the strategic and tactical need, including those of ballistic missiles. This need is being met by composite propellants.



In contrast, liquid propellant technology has shown no similar break-

through. To make this breakthrough composite propellants must be considered. It is the development of composite propellants which has made possible such propellant systems as the *Polaris*. It is possibly a polymer-based composite propellant, since Aerojet has done extensive work in this field.

These composite solid propellants are drawing great interest as the propellants that will speed tomorrow's rockets—such as rubberbase-polymers at Thiokol, as well as Aerojet's polyurethane-base.

Despite this advance afforded by composite propellants, solid propellant systems suffer a serious impediment. Traditionally, a solid propellant system is a constant energy device which cannot be metered for operation. This obstacle can and is being overcome, although the details are still classified.

If development of solid propellant military and research missiles is moving into the large-diameter long-range field that liquid propellant has had staked out for itself, then it is indicated that solid propellants are going to be next to impossible to stop.

Ion-Atomic Propulsion

The challenge, of course, to both liquid propellant and solid propellant systems is ionic or nuclear propulsion. Latest in the ionic propulsion category is the plasma jet with high temperature and low thrust. Solve the metallurgical problem of high temperature and boost the missile out to where the low ionic thrust is all you need and you're in business. It has been proposed that a rocket boosted to the ionosphere could pick up enough energy with solar batteries to continue on its way.

Barring an unexpected breakthrough, missiles of the immediate future will be propelled by liquid or solid propellants.

The propellant systems may, however, be hybrid. A system utilizing liquid oxidizer for a solid fuel has been designed. Systems such as *Vanguard* with the first two stages liquid and the last solid might be considered hybrid. But so then must all the liquid propellant missiles with solid propellant boosters and gas generators.

It is certainly possible that such hybrids will win out over "pure systems" of strictly one propellant. What will happen and has happened is that each system will be used, alone or in combination, as conditions dictate.

It is current operational conditions which are dictating the pronounced swing toward easily handled, increased performance, composite propellants. Startling new developments in solid propellants should be expected in the near future.★

need a match?

At Firestone, you'll find the right match for your wits – the match to explode your concepts into brilliant reality. The secret? Firestone's small-project approach to large-scale engineering problems.

For your career, this plan assures the broadest scope of achievement, with all the rewards of success. And of course, it also secures Firestone's accustomed role of leadership in guided missile and other defense projects. In a word, everybody wins!

The challenge is exciting. In Los Angeles, our major effort is the continuing development program for the Army's Corporal. In Monterey – Carmel-by-the-Sea, our new Engineering Lab is also blazing trails in guided missile and related fields. And don't discount this big dividend: while your career is going up, your family (and you) will enjoy living it up in California!

THIS JOB CAN'T WAIT!

The computer system for the Intermediate Range and Intercontinental Ballistic Missiles being built by Remington Rand Univac is vital to national defense.

The United States must be ready to deliver a swift and crushing counterpunch in case of enemy attack. The Univac® system would guide such missiles as the Air Force's TITAN and THOR on their missions of retribution.

There is immediate need for qualified men in Univac's highly essential ICBM program. Here is your opportunity to take part in a fascinating, crucially important project . . . your opportunity to find a permanent position and limitless future with Univac — world leader in the field of electronic computers.

Immediate Openings for:

ELECTRONIC ENGINEERS for component engineering, transistor circuit applications, circuit analysis and design, reliability, engineering test, component evaluation, quality control and specifications.

MATHEMATICIANS, BS, MS, and PhD levels for programming, math research, statistical analysis, data conversion. One to seven years' experience.

PHYSICISTS, BS, MS, PhD levels for research and development of systems and circuitry of digital computers, for evaluation of component reliability, and for physical research including evaporative thin film research and other solid state phenomena.

Also, other non-military career openings at our laboratories in Philadelphia, Pa., Norwalk, Conn., and St. Paul, Minn.

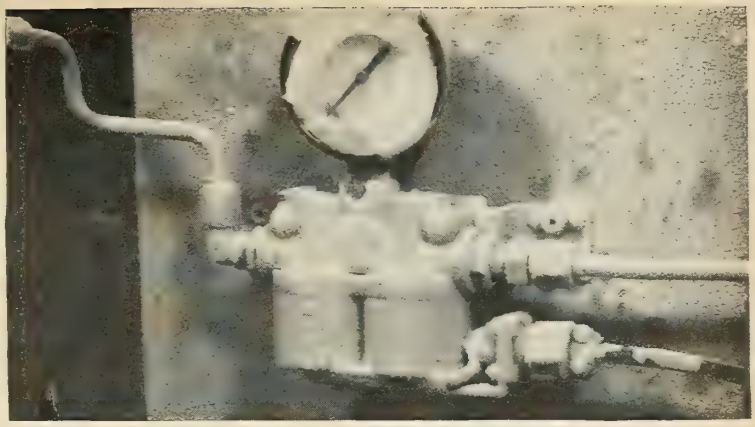
New High-Heat, Low Cost Fuel Reported

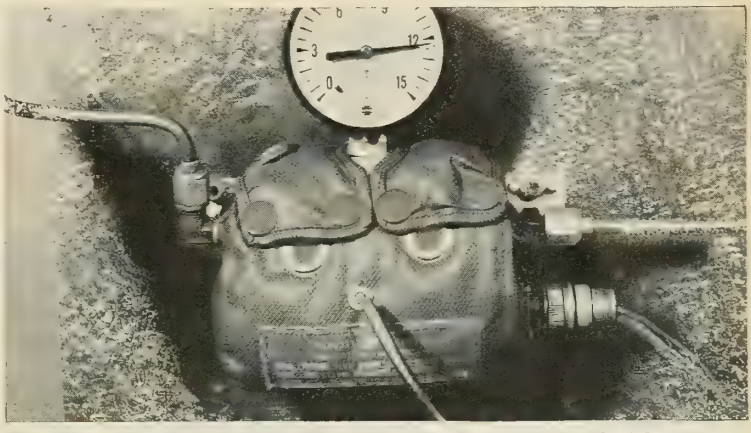
MISSILES AND ROCKETS has learned that preliminary work has been completed on a new concept in high energy fuels. The new fuel is said to combine ultra heat of combustion, good handling properties, and after a low molecular weight, all gaseous, smokeless exhaust. The compound and its combustion products are non-toxic. Further, the fuel is apparently stable when pure. Though not named, the fuel can be burned in air, or with any conventional oxidant. Reports state that higher heats of combustion (BTU/gal) over conventional hydrocarbons or metal hydrides are in evidence.

Perchloryl Floride Now on Market



Perchloryl fluoride, C103F, is being introduced by Pennsalt Chemicals. Available in pilot plant quantities, PF is a gas (bp-52 F) which can be safely stored in liquid form (critical temperature 203°F, critical pressure 53 atm, specific gravity 1.4). High reactivity is a feature of the colorless, non-corrosive material with a characteristic sweet odor. PF is said to be thermally stable to 500°C and stable to mechanical shock but reacts on contact with most organic materials. Acute vapor toxicity is placed at 2000-4000 rpm (4 hrs. exposure).

Oxygen Generating Plant Nearing Completion



New $5.5 million liquid oxygen generating plant now nearing completion at the Experimental Rocket Engine Test Laboratory at the Air Force Flight Test Center, Edwards AFB, will produce 150 tons of liquid oxygen daily, with 15 tons of liquid nitrogen per day as a byproduct. Latter is used for prechilling liquid oxygen missile tanks and pressurization of component missile equipment.

Solid Motor Cases Made of New Plastics

Polcarbonates-condensation products of phosgene and bis-phenyl-A are now appearing as high-impact and tensile strength plastics which may soon wind up as motor laminates or possibly as a fuel-binder for solids. GE has come out with its "Lexan" polycarbonate while Bayer of Germany and Eastman Kodak are also doing work with this material.

FREEZE-UP of solenoid-controlled valve in airborne system at −65°F can choke off vital air supply. Manufacturer faces tight contract delivery schedule.

SPECIAL HEATING unit custom-designed and delivered by G.E. in 5 days enables stock valve to function properly, saves customer time, money.

AIR VALVE OPERATING AT −65°F SHOWS HOW . . .

General Electric Specialty Heating Maintains Component Temperature

When components must be kept at operating temperature, G-E specialty heating equipment does the job! Thermal conditioning applications ranging from hydraulic and electronic components to tiny test instruments have all been solved by experienced G-E heating engineers.

LET US ANALYZE YOUR HEATING PROBLEM. Whether it's fast delivery on a prototype or quantity production, General Electric can provide specialty heating products engineered to your specific component needs.

Evolution of a Method

By George Shaw

Grotnes Machine Method Adapts to Production of Power-Plant and Missile Components

WHEN CHARLES C. GROTNES launched his business in 1898, building machines to produce tapered steel barrel hoops, his product was geared to that age. Today, more than 50 years later, they are doing essentially the same job of forming metals, but in a more complex manner and on a vastly larger scale; as much at home in the age of the atom as in the barrel shop.

Die casting, drop forging and stamping processes have been in general use almost as long as metals have been formed by machinery, but the method of altering the shape of cold metal by expansion and shrinking started with Grotnes. The basic principle involved is fairly simple and very adaptable. In fact, the magnitude of the jobs it can perform is only limited by the size of the equipment available, and this explains the enormous size and power of some of the Grotnes machines in use throughout the world.

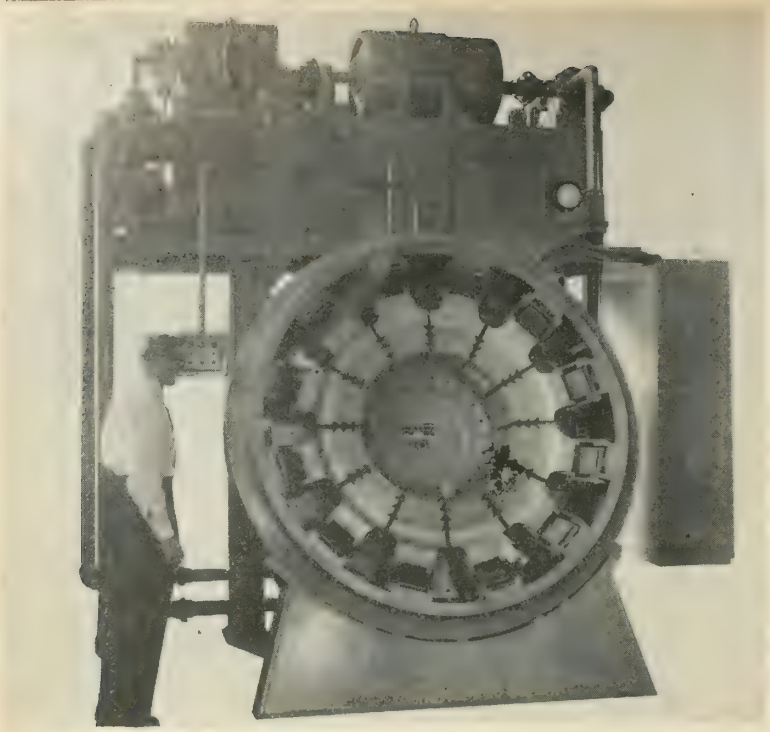
The name plate on a piece of Grotnes equipment bears the legend, "equipment for expanding—shrinking—rolling of metals." The legend suggests a line of exceptional machines which will form a piece of cold plate to almost any shape required at low cost and at a high rate of production.

It does not, however, suggest the wide application of these machines to an age that creates new and complex problems in metalworking almost daily. The wooden barrels have given way to guided missile parts and freezer cabinets; to washers and dryers and irrigation pipes, and the machines have kept pace. The method remains the same but the machines have grown in magnitude and in utility until today there is a Grotnes machine that will shrink or expand a piece of metal into a cylinder, a square or a polygon.

Demand for Auto Rims

Shortly after the turn of the century the automotive age began its slow roll into the realm of heavy industry. The new carriages, if they were to be really efficient, had to have steel rims for their rubber tires. Grotnes was called upon to develop a method to form and mass-produce the rims.

The hoop expanding machines were turned to production of steel rims, and Grotnes became associated with the tremendous surge of mass production in the automobile industry. Today practically all of the automobiles, trucks and agricultural machinery in the world roll on rims produced by Grotnes machines, or on machines using the Grotnes method.



Of the three basic operations comprising the Grotnes method the rolling operation is the least adaptable. While the rolling operation can only be performed on a cylinder or "coil," the expanding and shrinking operations range from, and to, any shape desired.

The cylindrical stock is formed on a weld roller, an operation that rolls the weld into the metal comprising the sheet stock and the weld is smoothed out on a Grotnes weld roller. This coil, as it is called, can then be rolled, shrunk or expanded to any shape required, without heating. Some of the more complicated operations may call for annealing between steps, but generally the forming is done without the need for treatment of the metal as in other methods.

In the production of a jet engine ring, the coil first goes to an expander where a channel or bead is expanded into the center section of the cylinder. This first operation facilitates the last one, where the coil is slit to form two rings identical in size and configuration. When the bead is expanded the coil is placed between two rings, one an expander ring and the other a hold-back ring. Corresponding dies in the two rings allow for consistent control of very close tolerances.

The coil then goes to the rim rollers for profiling. Two hydraulically operated spindles, mounting suitable tooling for the profile desired, form the rim in a continuous operation. The upper spindle is fixed, while the lower one is moved upward against the rim by hydraulically operated toggle linkage. Thus a differential can be provided in the gear train of one spindle and thereby reduce slippage between the roll and the part.

Rates of feed can be varied so that in any given operation the desired number of turns will be provided to form the desired contour. Cold forming of metals this way is said to materially improve the mechanical properties of the metal and uniform thickness is maintained throughout the part.

View looking into the 'maw' of a shrinker. Simplicity of operation can be seen in the control box arrangement at left. This shrinker sizes heavy ring sections of stainless steel, aluminum, alloy steel and titanium.

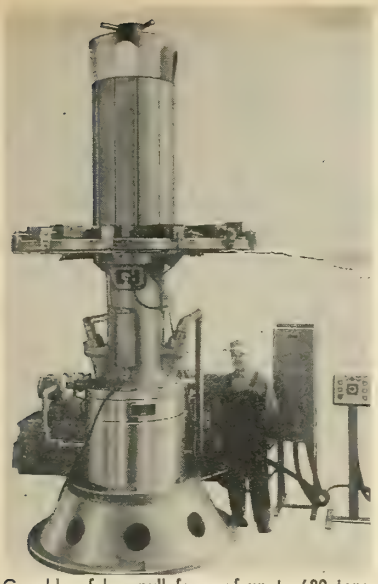
More ecnomical production is claimed for Grotnes machines than with processes which, in principle, can produce the same results. The reasons cited are, simpler manufacturing processes, versatility and adaptability. Quick changeover of forming rolls permits handling of a wide range of shapes and sizes of materials. As noted earlier the rim roller can only handle circular material; however with the expander and shrinker the dies on the machines can be adjusted to handle any shape.

The Grotnes expander is probably one of the most fascinating pieces of machinery ever devised for general application. No quality or characteristic of metal is overlooked in the design of expander principle and operation and surely there is no more versatile a mechanical apparatus in the metalworking field. To borrow a simile from the machine—any improvement in the expander is an expansion of the principle itself.

Such metals as mild steel, alloy steel, stainless, titanium and aluminum can be formed on the expander and the process is called the most economical means of forming and/or sizing any part having a continuous cross section —round, square, oval or polygonal. Subassemblies can be joined by the

Freedom is doing what you like. Some engineers like best to match their wits and skill against difficult technical problems.

This characteristic (or idiosyncrasy) of liking complicated technical problems will be one of the chief qualifications of the engineer we need. He will be required to study the multitude of interactions possible among advanced aircraft, missiles, and electronic devices with each other and with human elements in the nation's most extensive man-machine-computer system.



THE ELEMENT OF FREEDOM

To qualify, substantial prior experience with air-to-air or ground-to-air missiles systems is required together with demonstrated aptitude in the field of system planning. Call collect or write for more information.

System Development Division

The Rand Corporation

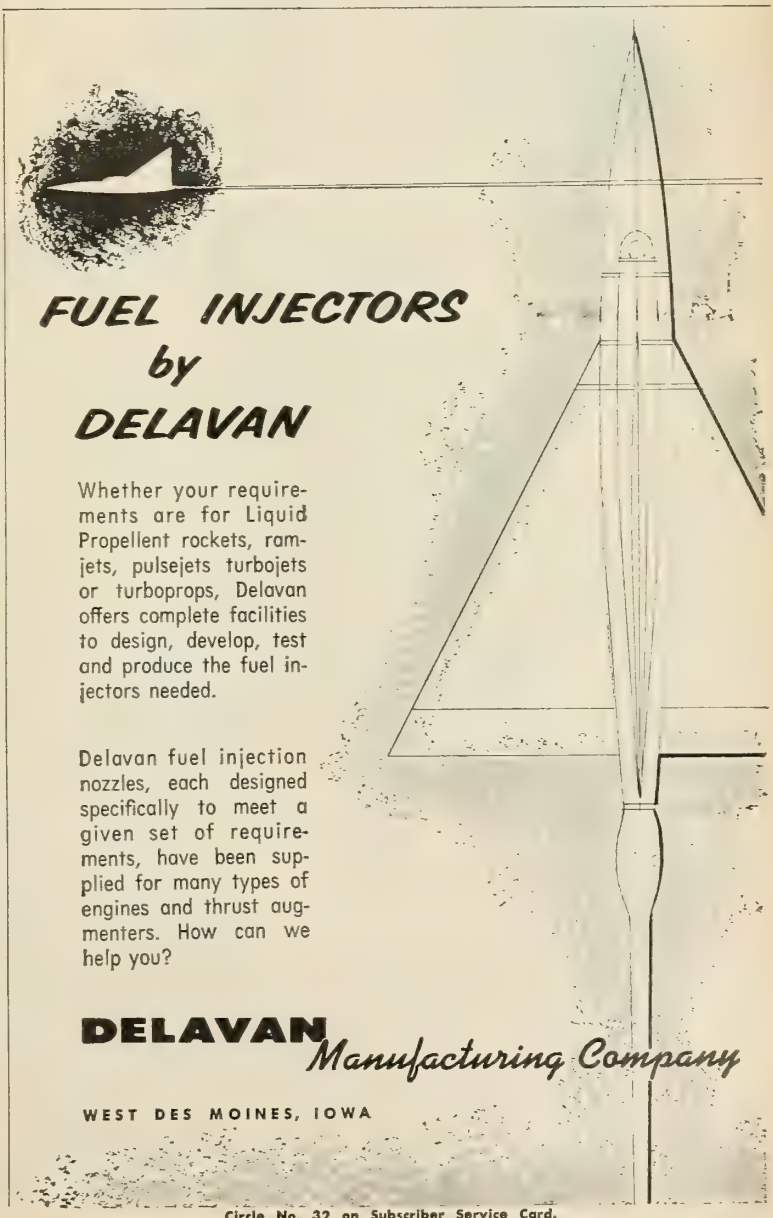
2414 Colorado Ave., Santa Monica, Calif. GRanite 8-8293, Extension 53 or 54

Capable of bar pull force of up to 680 tons, the machine pictured above is one of the largest expanders in general use. This machine sizes and forms jet engine parts such as cones, rings and cylinders.

process without resultant distortion such as with welding or bolting.

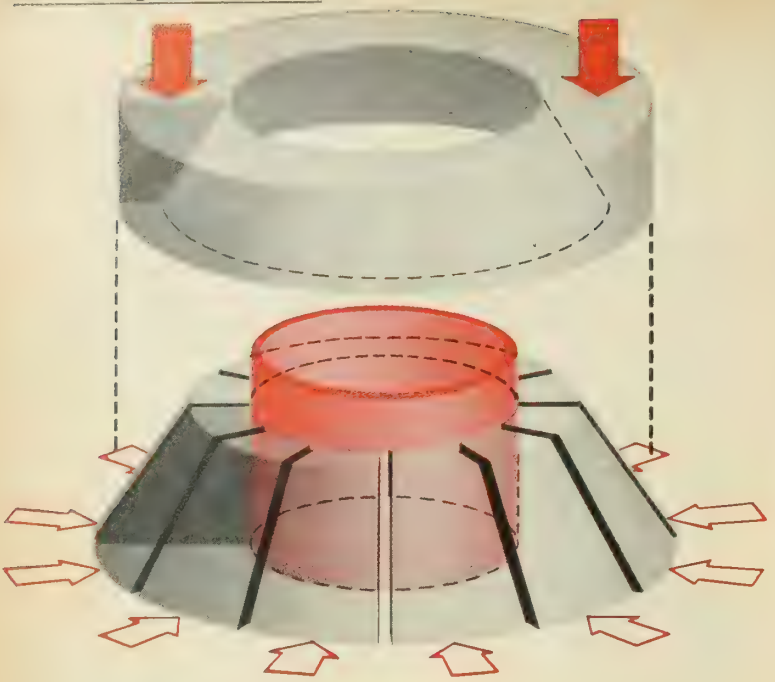
In another application such heavy sections as jet engine rings, hydraulic cylinders and motor frames can be expanded to rough size, considerably reducing machining time and material waste. Expanding is also widely used in testing weld strength and in improving welds and the adjacent metals. Though expanders are designed for use in forming a specific part they are generally adaptable to a certain degree.

The expansion process is simpler and more accurate than any other method known. For instance, in the case of a ring that must be joined permanently with another ring, one within the other, the expander usually does the job in one operation. The outer or larger ring is enclosed by a hold-back ring. The expander presses the smaller ring into the larger one in a permanent bond and the hold-back ring retains the shape and outside diameter of the whole. The inside diameter is established by the expanding dies.



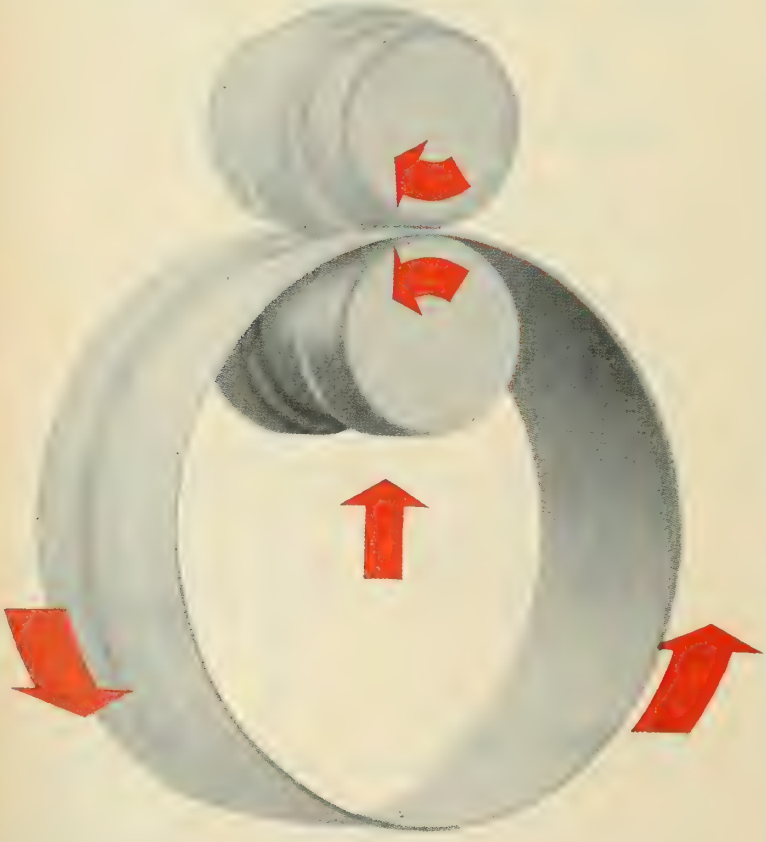
Although the bulk of expander production is concerned with circular or cylindrical parts, it can and does handle a variety of odd and unusual configurations. A wide choice of dies and die arrangements permits an almost unlimited choice of single and multiple operations to produce a desired shape. Once the machine has been set up and a couple of control tests are run, the machine can be run on a production basis, capable of extremely high production rates. A good example is a machine used in the container industry which will turn out 2000 curled, beaded, offset and flanged pails per hour.

As noted before, the basic principle of the expander is fairly simple. However, in the modern versions of the machines a number of inter-related variables tends to complicate the process considerably. The basic principle is that of the inclined plane or wedge, actually a polysided cone resembling a modified frustum of a pyramid. In addition to the cone the basic elements of the expander are the drawbar, jaws, table and power system. The cone is attached to the drawbar which may be hydraulically or mechanically operated.



The movement of the cone being drawn down between the jaws forces the jaws outward at right angles to the cone travel. The jaws move through slots in the table provided for this purpose. The dies for a particular operation are placed on the jaws and as they are forced outward they move against the part to be molded or expanded. The part is placed over the jaws and as the cone is drawn down the metal is stretched until the cycle of the cone travel is completed.

Wide Range, High Production Rate



The hold-back mechanism can be fitted with dies or it can be used as a simple retaining surface. When forming beads, or when a combination operation is desired—shrinking and expand-

Circle No. 32 on Subscriber Service Card.

Shrinking is directly opposite to expansion, the jaws being forced against the part by the descending ring, and is used where tolerances are critical.

Arrows show direction of rollers in forming a rim. Upper roller is fixed while lower one is actuated by hydraulically operated toggle linkage.

ing—corresponding dies can be fitted. An unusual feature of the expansion process is the tendency of stretched metal to spring back to its original shape. Though this action is minute it must be taken into account when setting the jaw travel. After the spring-back is calculated for a given metal and the jaws are set accordingly, all items processed with that setting are formed with identical OD and ID measurements, thus permitting mass production standards to be established.

By fitting the jaws and hold-back ring as noted earlier, a cylinder can be expanded to a square or a cone can be given a polygonic base. In fact, some of the combinations of shapes possible with expansion and shrinking are either impossible or impracticable using any other method. Because of the fact that the metal is processed cold, and that in most cases no machining is required, processing metal parts with the Grotnes Method and Grotnes machines is generally the most economical production standard available.

The question invariably asked is: "Where does the metal come from to allow for displacement in shrinking and expanding metal parts?" The answer supplied by the Grotnes Chicago office is sufficient of itself. It seems that the cold flow over the face of the dies in cold-forming allows the metal to be drawn from the entire body of the part, thus avoiding any local thinning or weakening. Amazingly, in such operations tolerances of no more than ±.002″ are maintained, a degree of accuracy which eliminates much costly additional processing.

The principle of shrinking is exactly opposite to that of expanding. In shrinking the jaws are forced inward by the action of a tapered ring or by toggle links. Shrinking is used where the amount of reduction in diameter is relatively small and where a higher degree of dimensional accuracy is demanded. Shrinking is often employed in conjunction with expansion, and as with expansion, shrinking is done with or without dies. A clear picture of this operation can be adduced by imagining the metal part being compressed by the action of a ring or mandrel being drawn over it.

Typical of the shrinker application is the reduction in diameter and sizing of the domed heads for compressed air tanks. Sizing is effected automatically to insure an inside diameter consistent with the cylindrical shell. Like the expanders the shrinkers lend themselves to a high rate of production.

The Grotnes principle, the company claims, can supply at least part of the answer to any problem of metalworking that might arise.★

Machining for Solid Propellant Rockets

cooperation between product engineer and hardware source can crack missile price barrier

By Joachim H. Kauffmann
President, Diversey Engineering Co.

THE MISSILE is a costly bird, particularly when you figure that despite all the love, labor and money that goes into it, just push the button once and . . . scrap! It's a throw-away item.

The taxpaying public has tolerated the high cost of researching and developing missiles with patience and understanding. The results, on the whole, have justified both patience and cost. However, whether either public or the economy will long stand for production missiles with research and development price tags is doubtful. The recent top-level AF missile cost symposium for major contractors is an example of the coming price consciousness. The desire for more missiles in less time for less money is becoming a national necessity.

In the case of certain vital components, such as rocket nozzles, forward domes, aft closures, adapter rings, accumulators and sometimes even nose cones, machining is often the only known practical means of obtaining the desired end product. Also, it's one of the costliest missile production processes. But costs have been cut in the past and, with proper cooperation between component supplier and end-product engineer, the missile price barrier will also be cracked.

Missile metal machining has progressed a long way since World War II. Technological advances in metalworking, machine tools and metallurgy have all played their part. But better methods breed more rigorous demands. Just as a manufacturer figures he's got a new and complex process down to a routine, along comes a rocket design requirement that demands closer

tolerances, more rigid specifications, more complex contours and a yet more awkward material to be machined.

Diversey Engineering Company now has contracts for machining parts for over fifteen major missiles including *Hawk, Titan, Sparrow, Falcon, Talos, Nike Ajax, Nike Hercules, Recruit, Lacrosse, Polaris, Deacon* and others. The missile materials the company works with include aluminum, magnesium, titanium, aircraft quality steels, nickel-cobalt alloys and molybdenum.

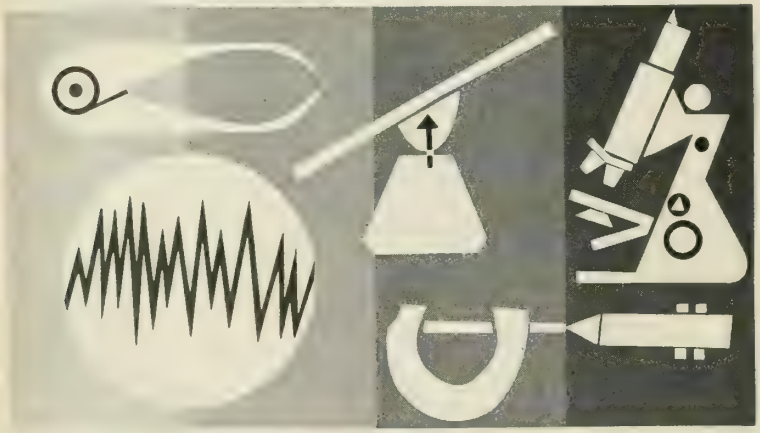
As with any component supplier, it is the responsibility of an engineering company specializing in complex machining to keep its processes and techniques not only up to the job, but on as low a cost basis as possible. It is also its responsibility to keep its market constantly aware of latest developments. Just as missile system research and development teams must propose and test, so must a missile machine shop experiment with and try to develop new and promising processes.

It was just such an effort that proved the full worth of the air tracer lathe—today's mainstay of missile metal machining. And it is just such a similar effort with hydro-spinning and hydroforming that will result in new design flexibility and production economy. Diversey has pioneered in both these fields and now has the largest single contract supply of Monarch air tracer lathes in the U.S.

Above: Four stages in the production of a solid propellant rocket nozzle—rough casting; rough machining; finish machining; threading. To the right, a solid aluminum billet begins to take shape as the core mold for fixing shape of solid propellant burning surface.

In the last eight years development of this equipment has put three dimensional contour tracing on a mass production basis, enabling the rapid repetitive machining of complex missile parts that would otherwise require costly, time-consuming hand work. Hydro-spinning shows particular promise in the production of rocket cones, nozzles and tubes.

To get an idea of the complexity of process and rigidity of specifications in rocket machining takes only a quick look at the quality control requirements imposed in a missile contract.



Each machined part has its own serial number coded to files containing as much inspection and process data as the health record of a VIP at a modern hospital. These cover material analysis, heat treatment of components, subassembling, magnafluxing, radiological and fluorescent dye penetrant inspection processes, hydrostatic testing and finally the bug-a-boo of all missile hardware: strict reliability.

These demands cause a veritable blizzard of metallurgical, quality control reports and certifications to accompany each component to the final assembly point. Precision inspection equipment for examining finish surfaces, contours and dimensions alone in such a plant as Diversey may represent a capital investment of $100,000.

The machining, for example, of one solid propellant rocket nozzle calls for a three dimensionally contoured wall of tapered thickness to be machined to an internal dimensional tolerance of ±0.001 inch and a surface finish of at least 32 microinch. In another case an accumulator's internal dimensions must be held to within +0.0005 inch, —0.0000 by machines designed for normal tolerances of ±0.001. And these machine tools are the best available.

The problems in machining rocket parts are varied. The major one is that standard straight line machining is not acceptable. Items of solid propellant motor hardware generally have one similarity—thin-walled contoured sections. This necessitates the employment of contouring machinery on a greater scale than in any other industry. Thiokol, Allegany Ballistics Laboratory, Aerojet-General, as well as other designers have this common requirement. Diversey specializes in satisfying these needs.

Solid propellant rocket hardware is not as varied as in the liquid engine

HOW WHITTAKER GYRO ENFORCES QUALITY CONTROL

Problem: Provide customers with highest quality gyros—time after time—through quality control.

Solution: 1) use standardized components which have been tested and proven, *2)* a higher training level, *3)* use more detailed assembly instructions, and *4)* set up 100% inspection tests for any customer requirement.

Result: An overall customer rejection rate of less than 2% for Whittaker Gyros.

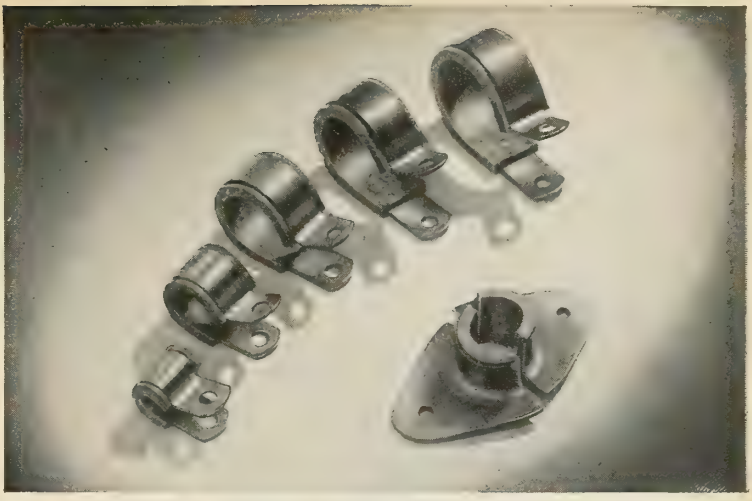
Circle No. 33 on Subscriber Service Card

field but has specific problems all its own. The major hardware items are: a cylindrical case, forward domes, aft closures, adapters and nozzles.

Nozzles are either bolted or screwed to the aft section of the motor case to facilitate the loading of the motors. The case assembly is either rolled and welded, deep drawn or of laminated construction.

The most commonly used alloy steel in this fabrication is electric furnace, aircraft quality 4130 (MIL-S-6758). This hardware with exception of nozzles is generally welded to the case. The whole weldment is heat treated to specifications which spell out yield and tensile properties or they merely specify a hydrostatic pressure test for specific time periods.

After heat treatment of the motor assembly, several surfaces must be remachined to assure alignment of the nozzle. Concentricity and squareness of these surfaces are critical and tight tolerances are spelled out. For example, concentricity and squareness of a typical solid propellant motor assembly might be as close as $\pm$.005 on concentricity over a 12 foot length and squareness and parallelism of .003 inches on all trued up surfaces. This is to be attained on a weldment.



The problem is not so much doing these things, once or twice. It is the development of production methods that enable them to be done on a nearly automatic, repetitive, low cost basis.

Utilizing contour turning techniques permits the design engineer to cut his lead time from prototype to pre-production or production of a solid propellant hardware item. He has the time saving advantage of being able to specify all complex details on a single template, instead of being forced to delay machining until special form tooling, cams and checking fixtures are constructed.

The details are simply machined on a thin plate of good quality steel and can be checked in any modern inspection department, either by standard vernier and radius gages or by comparator. If the template is properly machined, the job is ready to run.

A typical example of this problem is a large, solid propellant motor adapter. The contours are complex, tolerances and surface finishes critical. To fabricate the part properly, it requires a forging designed to give optimum strength. The units are rough machined, using a roughing template in a tracer lathe, to a $\pm$.010 inch tolerance to control heat treating results. Finish machining is done in the hardened state to surface finishes as fine as 16 microinches and dimensional tolerances as close as $\pm$0.0005.

With proper utilization of new

Anyone can make a metal clamp, but one lined like this takes a bit of doing

Take asbestos, reinforce with wire mesh, impregnate with DuPont Teflon and mold to shape . . . a new conception in high temperature clamps, one
–that will take temperatures from —300 to +500 F
–that will never harden nor melt
–that will stand corrosive fumes, oils, hydraulic fluids, solvents, fuels
–that will absorb constant vibration and stay on the job
and do its work. Write for samples and quotations.

turning principles and cutting tools, such as ceramic "throw-aways" and the harder carbides, superior finishes can be attained on modern, rigid lathes which are tracer controlled and can repeatedly duplicate difficult contours and sweeping radii to close tolerances.

In machining hardened missile components, exceptional results have been obtained on air-gage tracer lathes using ceramic tool bits, M-95 and K7H carbides. High velocity turning up to 1000 surface feet per minute—three times what steel is normally turned at —imparts excellent surface finishes ranging between 32 and 63 microinch, thereby eliminating costly grinding and polishing.

Manufacture of core molds for casting the solid propellant is a constantly expanding field. Long contoured tapers are milled on aluminum bars or extrusions in a variety of shapes such as star or cruciform configurations. Extreme care is needed to maintain concentricity along each of the tapered planes in order to ease the extraction of the core from the solid propellant. Generally, all cores are coated with Teflon or a similar substance.

The welding of solid propellant components must be rigidly controlled due to the fact that after welding and heat treating, the only machining that is possible on motor case assemblies and subassemblies are light finishing cuts to true up the axis of the case to the nozzle and to the adapter. Jigs for holding components during welding must insure the end product being as concentric as possible. Since all assemblies are subject to hydrostatic test and/or radiological inspection, welding specifications must be strictly followed.

Care must be taken in heat treating that a minimum of distortion takes place. Here again, due to the thin wall, uneven sections of solid propellant components, a thorough analysis must be made of each component prior to heat treating.

When considering production items from a cost point of view, design and engineering groups should work closely together to ascertain whether an investment casting out of the proper alloy steel can be used by simply machining out the area matching the external dimensions in the components and welding same in place. This can result in great savings in manhours, scrap and lead time.

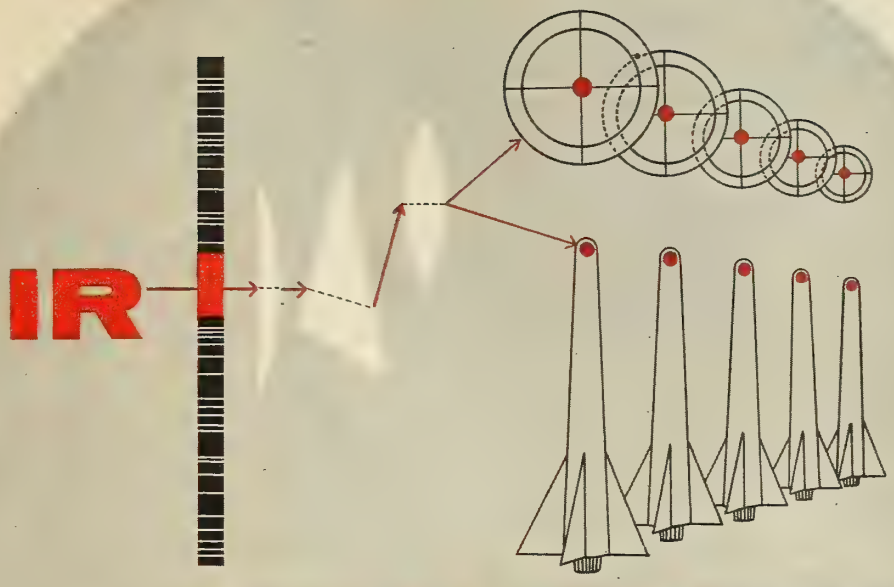
In most instances this 5000-year-old "lost wax" casting process provides physical properties that meet design standards. It is entirely possible that it may prove as economical and useful in rocket motors as it has in turbine engines and other ordnance gear.

Actually, when a missile or rocket

Among the many requirements for heat elements in industry today are those demanding virtually one-of-a-kind design.

Since such requirements normally cannot be met by loom weaving, Safeway technicians fabricate odd-shaped elements individually. Circles, half circles, cutouts, tapers and compound shapes are just a few of the elements fabricated in this fashion and produced in quantity.

Insulation, too, must provide for the characteristics of specialized applications. Safeway produces a wide variety of elements insulated with neoprene rubber, silicone rubber or reinforced plastics.



If you have a problem that requires heat, let Safeway engineers study your requirements and—without obligation to you—submit an appropriate recommendation.

motor is scheduled to go into production, all specifications and tolerances should be given a close second look. For example, is it necessary to pay the heavy premium of machining a rocket motor adapter to thousandths of an inch when it's going to be given a plastic liner accurate to hundredths?

When a missile is in the research and development stage, designers are worried primarily about making the *system* work. There may be a tendency to over-specify materials and tolerances in order to preclude failures due to simple mechanical failures. However, once the system is proved it may well be possible to ease specifications, particularly of individual components. Easing the preparations for machining and the material to be machined, minimizing tolerance — all tend to reduce machining costs. Molybdenum costs more to machine than titanium; titanium, more than steel; steel, more than aluminum, etc.

By machining one component, now in full production, out of an investment casting rather solid stock, per unit costs may be reduced from $800 a copy down to around $200. When the order entails thousands, this is a major cost factor. Considerable cost savings may also result when, say, the external tolerances and finish on an accumulator are eased. Wherever closer tolerances are called for, cost goes up exponentially.

This is the job of the production or process engineer. Its his task to design producibility into production missiles—to check every specification the design engineer calls for; to point out to him differences in costs of various materials, various production methods, tolerances, etc., vs. the difference in performance (if any). This is a vital phase of anything scheduled to go into production, missiles and rocket motors included.

Low Cost Hydrospinning

In this connection, hydrospinning may prove as useful over the next decade as the air tracer lathe is now. Hydrospinning is a cold process in which the work piece is forced to take the shape of a hardened rotating mandrel. Its great usefulness is in the manufacture of hollow symmetrical parts of tubular or conical shape, and is particularly advantageous where walls of varying thickness are required.

In some missile operations now requiring careful contour machining, hydro spinning will save 80 per cent in machining time and 50 per cent in machine costs.

The big plus, however, is in savings in material and time, increase in tensile strength and fatigue resistance and, in some cases, reduction in weight

as a result of cold working. In addition, an excellent finish is obtained on the inside surfaces. Outside diameter finishes are frequently satisfactory in the "as spun" condition.

During hydrospinning, the metal being formed undergoes shear deformation. Work hardening accounts for an appreciable increase in tensile and yield strength. Elongation is decreased proportionately. The process has many advantages in the case of cost cutting and mass production.

At present, cones with an included angle of 30° can be spun from a flat blank. This is a blank reduction of 75%. Lower degree angles can be obtained if the part is preformed. For cones of varying wall thickness, a premachined blank is required.

In the event contours other than those of parallel or angular size are desired, a contour attachment can be used to obtain the necessary shape. This combination of contour hydrospinning lends itself admirably to most solid propellant rocket motor parts.

For tube spinning, hydrospinning basically amounts to cold extrusion. Raw materials can be in the form of cold drawn tubing, hot rolled tubing, rolled or welded blanks or, in some instances, preforms machined from forgings. Because of the tremendous pressure applied, welding defects in welded blanks will show up as a defect in the surfaces of the tubing, thus providing excellent welding inspection. Maximum recommended wall thickness for the tubular blanks is ¾ inch. Some tubes have been spun with a reduction as high as 90%.

In regard to reliability, the missile hardware machining source must exercise strict reins on quality control. Top management must instill a feeling of absolute responsibility in all branches of the facility. Supervisory personnel, as well as machinists, welders, assemblers, testers and quality control personnel must be thoroughly briefed on problems to be solved, processes involved, high quality of workmanship, etc. The whole missile hardware plant must take the deepest interest in all operations. "The end items can only be as good as are the capabilities of the men that manufacture them. A feeling of pride and intense interest must prevail throughout."

As the solid propellant field widens, more unusual demands will be made on the hardware source. It is imperative that this source stays abreast of the newest developments in machine tools. Design, project and process engineers must be informed of these developments and urged to adapt their designs insofar as possible to manufacturing processes with optimum producibility.★

BURROUGHS RESEARCH CENTER NEEDS *Good* ENGINEERS

ALL THINGS ARE BORN IN THE MIND OF MAN

. . . it is the responsibility of the engineer to develop these thoughts for practical, profitable use.

All ideas are but a result of what has gone before and man's ability to adapt his vast store of acquired fact to reason. His mind, when used efficiently, is the most prolific of all computers — it can think, remember, reason and store information better than any man-made machine. This deep reservoir of conscious and unconscious knowledge residing within the thinking individual is a scarcely tapped source of a whole torrent of ideas.

As these new ideas unfold, it will be the responsibility of the engineer and scientist to apply his practical experience and trained reasoning to these new concepts . . to develop them for the most practical and beneficial use.

That is *just* what we are doing at the Burroughs Research Center. If you want to be a part of these exciting discoveries in the field of electronic computing, why not look into the Burroughs story today?

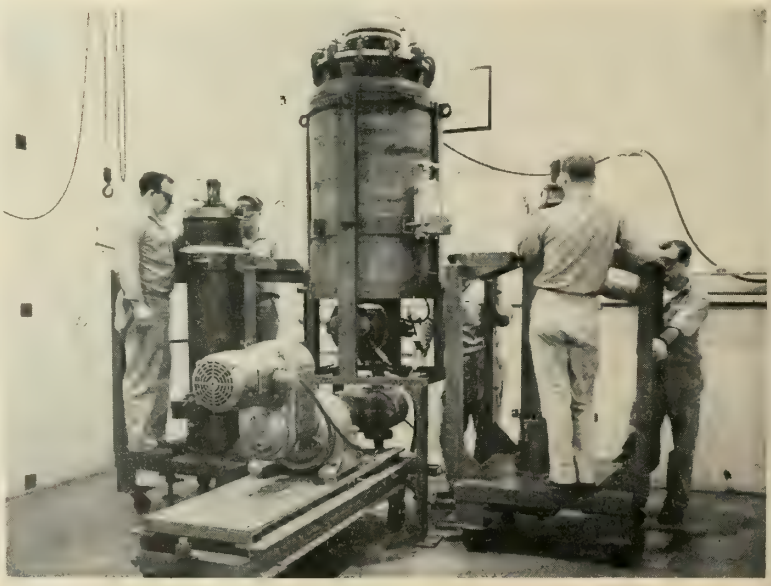
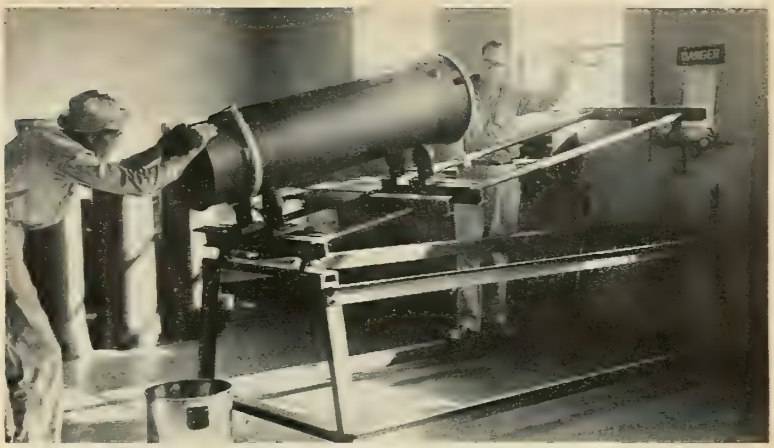
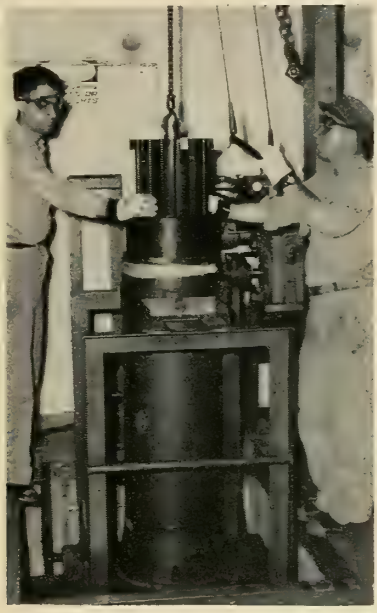
Processing for Solids at Thiokol

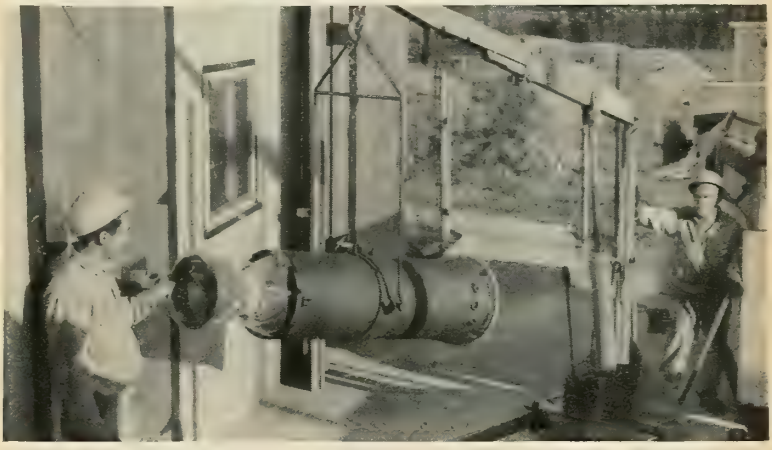


Vertical rocket motor test. The complete rocket motor is subjected to test firing during development (over a very wide rocket motor temperature range). Selective sampling of production motors is a major effort of the testing team. A vertical test pit and allied instrumentation surrounds the motor in this scene and only hot exhaust gases are shown.





LEFT—Remote operation scene. A technician operates a machine from behind a revetment while viewing the operation through a port-and-mirror. RIGHT—Composite propellant mixer in a tilted position as used during discharge of the propellant from the mixer to the transfer can. The Baker-Perkins mixer accommodates about 1,400 lbs. of propellant. The mixer is jacketed and a heating fluid is used to control the temperature of the propellant during mixing.



Propellant (polysulfide, composite type) in the raw state is pumped from the large transfer can into two rocket motors. At this stage the propellant is a very viscous fluid which flows into the lined rocket motor case. The loaded case will be placed in an oven to cure the raw propellant to a hard rubber solid that bonds to the lined case.

Rocket motor case being prepared for lining operation. Each case is first tested, inspected and cleaned. Liquid rubber made by Thiokol is then applied to the entire inside surface of the case and a thin layer of this lining rubber is cured. This thin layer bonds to the case and provides an excellent surface for later bonding of the propellant.

Transfer of a rocket motor from a temperature conditioning chamber to a test cell. Each rocket motor is conditioned to a known temperature prior to test firing thus eliminating one variable from the evaluation of motors during development. This procedure is also used to demonstrate the wide operating temperature range of which these motors are capable.

Removal of the core. A core is placed in the raw propellant prior to cure of the propellant. The core is subsequently removed leaving the desired internal cavity in the case bonded propellant. During burning the flame front progresses radially outward from the internal cavity thus the case is protected by the propellant from the hot gases.

The Army's most sophisticated tactical surface-to-surface missile, LACROSSE, leaves a searing flame in its wake during launch from White Sands Proving Ground. Flame is produced by one of the largest production solid propellant motors—an achievement of the Thiokol Corp. The motor's propellant has a synthetic rubber base, containing an oxidizer.

AC Spark Plug Developing *Regulus* Guidance System

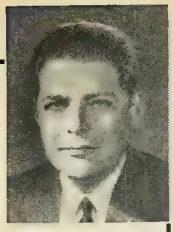
A new type of guidance system for the Navy's *Regulus* missile is under development by the AC Spark Plug Division of General Motors, as well as a guidance system for the Martin *Matador*. Chance Vought Aircraft, builder of the *Regulus*, reports that the missile has already been checked out at altitudes in excess of 50,000 feet and at speeds of Mach 1.5 and above. The *Regulus* system is being handled by AC's Milwaukee plants.

Servo Corp. Builds *Sidewinder* System Tester

Testing and calibration of the *Sidewinder's* infrared detection system is done with an infrared radiation standard developed by the Servo Corp. of America. The Government and Industrial Division of Philco Corp. used the IR device to test the sensitivity of the lead sulfide cell, the heart of the *Sidewinder*.

Sidewinder, the Philco-Navy developed AAM for Navy fighters, is the first missile to successfully use the infrared homing system.

Radioplane Receives Army Target Contract



Radioplane Co. has been awarded a $4.5-million contract by Army Ordnance for providing target flight service to the Army's surface-to-air missile training program at Fort Bliss, Tex. One of the first of its kind to be awarded, the contract requires that Radioplane Company provide not only aerial targets and ground support equipment, but operational, training, and maintenance personnel as well. Field headquarters for the program will be at the Radioplane plant in El Paso, Tex.

Missile Master System Will Support *Hawk*

Missile Master, an electronic system for controlling and coordinating fire of *Nike* anti-aircraft batteries, will also be used to coordinate the *Hawk*, the low-altitude air defense missile, according to a recent Army announcement.

Missile Master is manufactured by the Martin Co. at interim facilities in Orlando, pending completion of the company's Orlando Division plant.

Circle No. 60 on Subscriber Service Card.

Astrionics

By Henry P. Steier

"Our kingdom for a transistor," could be the next utterance of IGY scientists. Serious delays in obtaining enough camera tracking equipment for the satellite program are raising questions as to what it would mean if a satellite were launched without them.

Dr. John P. Hagen, Project *Vanguard* director said recently that we can go ahead safely with Minitrack alone. There must be something lost if the cameras don't materialize on time: It is the degree of accuracy with which data on the earth's shape, gravitational field, atmospheric density, etc., will be obtained.

Use of the cameras would add a whole order of accuracy to such data and new orders of accuracy are a prime goal of IGY work. If only a 1000 megacycle transistor were available the cameras might not be needed.

Minitrack's tracking accuracy limitations will be set by refraction of the satellite's 108 mc signals as they pass through the ionosphere. The angles from which the signals come will be "apparent" not real. Minitrack's designers say raising the signal frequency to 1000 mc would enable Minitrack to compete with camera tracking accuracy.

•

Results of six years surveillance of military electronics in the field have been published by Aeronautical Radio Inc.'s Reliability Research Department. The work should go down in history as a definitive study of unreliability and what causes it. If ever a study was conducted to highest scientific standards of observation and classification of facts this one was. In the face of much talk about unreliability and superficial treatment of it by many segments of industry, this work should, after a close study of its conclusions, be very convincing as a guide post to do something about unreliability, in all electronics work.

•

New rallying point for strolling satellite enthusiasts ought to be International Business Machine Corp.'s new *Vanguard* computer center at 615 Pennsylvania Ave., N.W., Washington, D.C. On one side the new building houses a most colorful display of gold-plated satellite, rocket engine, optical and radio tracking gear, and guidance devices. On the other is equally colorful IBM 704 computer that will keep scientists and the public posted on "how goes it." Not open to the public, the building was designed for sidewalk viewing. It's the newest addition to the "sights" in Washington.

•

Navy will soon give radio astronomy a field tryout on board the U.S.N. Compas Island to determine usefulness for navigation of missile ships and submarines. All weather position-fixing capability is needed. Pioneering work in the field of radio astronomy by Dr. John P. Hagen to codify radio signals from various stellar bodies may soon pay off as a new means of navigation. Navy says the large-antenna problem has been overcome and now antennas suitable for shipboard can be used.

•

If you see a *Moccasin, Rattlesnake*, or *Copperhead* missile name don't be surprised. It'll belong to the *Sidewinder* family of infra-red tracking missiles. We just learned from Dr. Alvin Novick of Harvard University that nature was way ahead of us on use of this tracking method. These snakes belong to a species known as Pit Vipers. On each side of the head between the nostril and the eye is a sensory pit. It houses a heat radiation detector that enables these cold-blooded creatures to track warm-blooded creatures at night. *Sidewinder* snake is one of this species.

ENGINEERS

Electronics, Aerodynamics, Propulsion

Information manual about APL and its programs now available

The Applied Physics Laboratory (APL) of The Johns Hopkins University is unique in that we are neither an industrial nor an academic organization, but rather a composite, having drawn freely from the methodologies of each.

For thirteen years APL has pioneered in guided missiles. Today we are engaged in a broad program of R & D for the Navy; in addition, we are responsible for technical direction of industrial and academic contractors in developing the Terrier, Talos and other major weapons and weapons systems. Our staff members enjoy not only the stimulus of association with their immediate colleagues at APL, but also with those in other organizations of considerable stature.

NEW 30-PAGE PUBLICATION

A few positions for senior engineers and scientists are now open. Information on our accomplishments and goals is available in a new 30-page publication, just off the press.

In it staff leaders representing each of the various disciplines and fields outline the nature of their programs. Information on our new laboratory in Howard County, Md. (equidistant between Baltimore and Washington) is also included, together with facts on the outstanding communities in which our staff members live.

Quantity is somewhat limited. May we suggest you send now to: Professional Staff Appointments,

OPEN TEMPERATURE PICKUPS

The illustrated OPEN TEMPERATURE PICKUPS are precision platinum resistance thermometers capable of high-speed temperature measurement of gases and non-corrosive fluids. Resistance winding, supported on ceramic-insulated posts or on card, is in direct contact with environment to be measured, and can have time constants as fast as 50 milliseconds. Full-scale output voltages of 5 volts can be delivered directly to telemetry commutation circuits. Units operate over selected ranges from −320F to +750F (−200C to +400C), with accuracy better than ± 1% of full scale and repeatability of ±0.2°C. Calibration Certificate giving precise 5-point calibration supplied with each unit. Stainless steel case and rugged construction withstand 1500 psia pressures, ±25 g vibration, and 60 g shocks under MIL-E-5272A. Send for Technical Bulletins 1182 and 1350.

Space Medicine

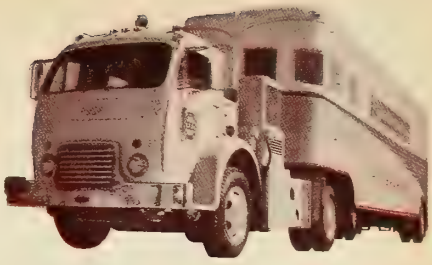
by Hubertus Strughold, MD., PhD.

The following is a report covering the symposium on "Problems Common to Astronomy and Biology" held in Flagstaff, Ariz., June 18. The occasion was a joint meeting of the Astronomical Society of the Pacific and the International Mars Committee.

A paper by Lt. John A. Kooistra, Jr., Dr. Roland B. Mitchell, and the writer, dealt with the behavior of microorganisms under conditions simulating those of Mars. It attracted much interest among astronomers. In these experiments soil samples obtained from the Painted Desert in Arizona, and samples of lava, etc., with their inherent microflora, were exposed to a combination of lowered barometric pressure, altered atmospheric chemical composition, reduced moisture and low temperature as these conditions are found on Mars.

Preliminary results show that there has been a trend of the dominant micropopulation originally in the soil samples to change into a different type of population capable of surviving and multiplying under these conditions. Some of the microorganisms gradually disappeared from the original sample. The experiments represent a completely new approach to the question of life on other planets and to astrobiology generally.

At the same meeting Dr. Ingeborg Schmidt of the University of Indiana at Bloomington, a specialist in color vision, discussed the applicability of recent advances in physiological optics to astronomical observation. She included new data on color vision, night vision, contrast vision, etc.

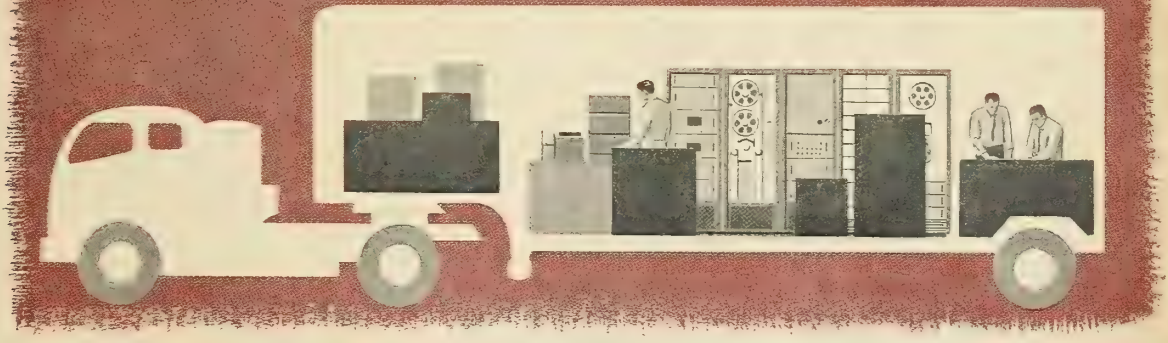


After the Symposium, color vision examinations were given by Dr. Schmidt. It is well known that about 4 per cent of the male population as a whole and only 0.3 per cent of the female population, are defective in color vision. These examinations attracted special interest because of the controversies extending over many years about the various colorations found on the planets. Of the 30 persons examined, six were color defective to a greater or lesseor degree. Information on these cases were, of course, kept confidential by Dr. Schmidt.

In another interesting paper, Maj. David G. Simons, USAF (MC) from the Aeromedical Field Laboratory at Holloman AFB, N. M., discussed the possible use of sealed gondolas in high-altitude balloons as astronomical observatories.

The International Mars Committee, with headquarters at the Lowell Observatory on Mars Hill in Flagstaff, will continue its work. Dr. E. C. Slipher, Director of the Observatory, is the Committee's Chairman. Dr. Slipher conducted studies of Mars during its oppositions in 1954 and 1956, at Bloemfontein, South Africa. (See his report in the National Geographic Magazine of September 1955.) Dr. Gerard De Vaucouleurs, noted French astronomer and author of the book "Physics of the Planet Mars," is secretary of the Mars Committee. He is now in Flagstaff.

The educational television series on Space Medicine has been completed. (As I have reported, the script is by Mr. Green Peyton, Chief of Information Services at the School of Aviation Medicine; the films are produced by the University of Houston; the series is sponsored by the Ford Foundation). In one of the last two films Dr. Albert G. Wilson, Deputy Director of the Lowell Observatory, is seen discussing conditions on other planets with regard to their ability to support life. In the final one, Major General Bernard A. Schriever, Commander of the Air Force Ballistic Missile Division, Air Research and Development Command, appears in a discussion of the human problems raised by satellites and missiles.



Best solution for high-speed flexibility

Put your data-processing lab on wheels

These Trailer Labs—designed and built by Consolidated's System Division—soon will be delivering fast, on-the-spot test data for several aircraft companies. Buyers know that the only efficient location for a data-processing center is at the site where the work is being done. CEC solved this problem with an efficiently designed, integrated system custom-built to do a precision job anywhere. Raw data can be introduced in the form of analog information which is processed at high speed to digital form as punched cards or tabulated summary sheets. Your company can profit with this high-speed flexibility. Let CEC's System Division show you how quickly a custom-designed Trailer Lab pays for itself. Contact your CEC field office for complete information.

CEC's SELF-CONTAINED DATA-REDUCTION LABORATORY

Your company can take advantage of this convenient high-speed system . . . and at no extra cost. For proof, contact your nearby CEC field office, or write for Bulletin CEC 1304-X44.

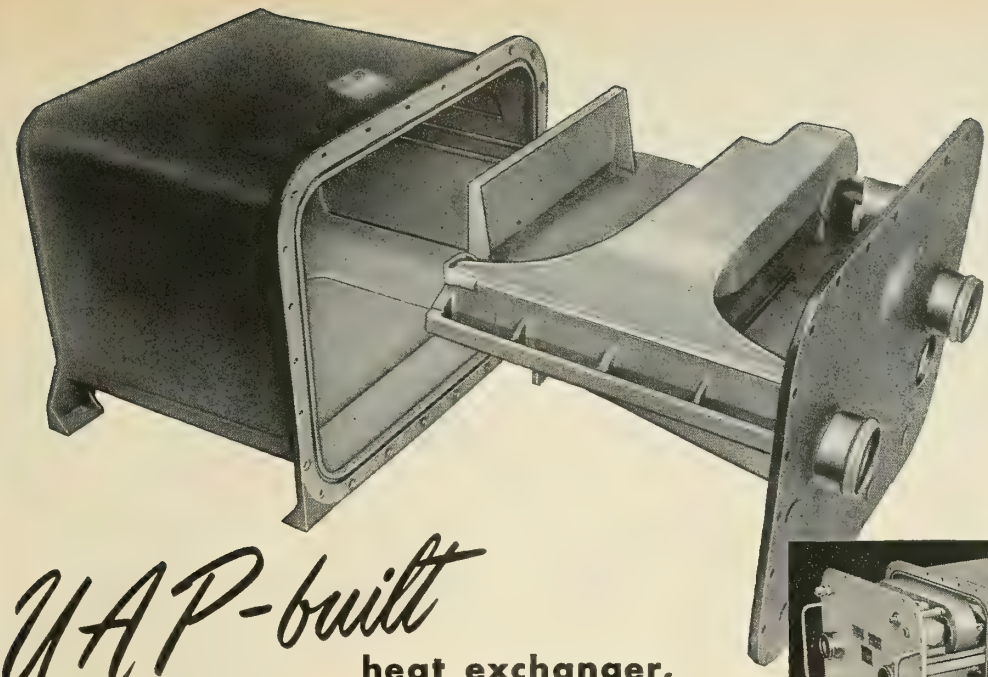
Missile Miscellany

By 1/1/58, this page hears, solid propellants will be able to do anything liquids can (and more) with greater safety, readiness and reliability--all at less cost. This includes city-killer missile ranges up to 12,000 miles and large satellite vehicles. In fact, from propulsion viewpoint, new SPR mass ratios may obsolete Titan, Atlas, Thor, Jupiter overnight.

But then, National Bureau of Standards has produced atomic nitrogen and oxygen: possibly atomic hydrogen and the hydroxyl ion. Made at 2450 megacycles, they are stored at 4.2°K by molten helium. So goes the see-saw.

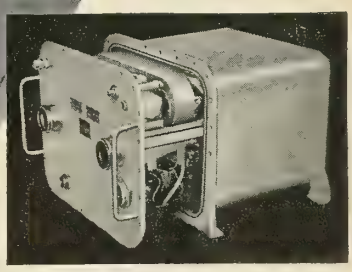
Add the Navaho demise, White House missile ire, etc., and signs are many that the young, precocious, expensive missile industry is heading for a jolting shake-out. While some companies will fall, stunned and flattened or wholly shattered, others will rebound vigorously from reality's hard floor. And the missile business, emerging from the remains of the aircraft industry, will headline new names among the old. This page figures the future's for those who stick to facts; that for those who would cite fact and fiction as one, tomorrow will be rough; end early. And speaking of facts, like dates, those who have reason to fear the first shake should beware the ides of October.



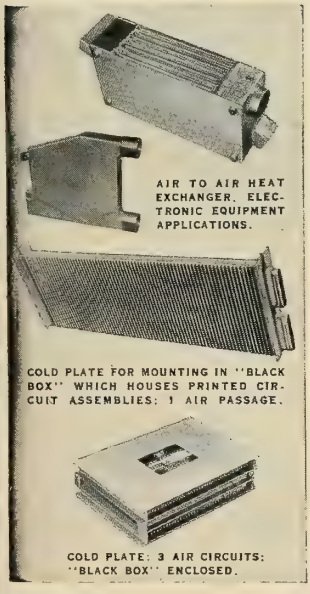
All of which goes to a bit of morning coffee philosophy: Namely, that the missile industry cannot long survive based on the premise that (apologies to P. T. Barnum) "a taxpayer is born every minute!"

And as a further sign of the times, other groups similar to Omar (Olin-Mathieson, Marquardt, Reaction Motors) are forming. Their avowed goals: Take missile business away from the aircraft industry; develop civil uses for rockets. Their means: Production knowhow. Watch their stocks.

In contrast to $269 million in reentry nose cone development contracts to GE and AVCO, this page recently heard a Wilmington company claim it can meet the need with ease and inexpense of a potter spinning soup bowls. An NACA-tested 1/2-inch thick disc of its material failed to disintegrate or crack under 20-second blast of 12,000°F plasma jet.



And back to a favorite subject: What happens to a sub-critical mass of plutonium that's accelerated to relativistic velocities? And another: Why won't heat flow faster when the potential difference is greater?



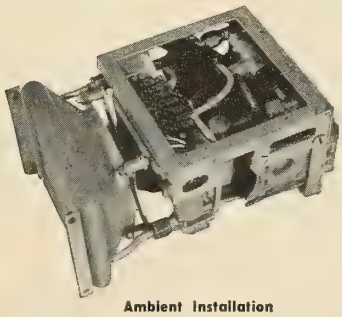
Lest we forget, missiles are a tough business as witness accelerations of plus or minus 40 G's at frequencies up to 600 cycles imposed on missile body by Snark boosters . . . And from the University of Dayton word of work on a reentry test vehicle . . . A rumor that AF may do operational testing of big missiles with nuclear warheads from Pacific coast because of danger of clobbering South Atlantic friends and possible fact Soviets have Florida range better instrumented than AF . . . Suggestion that wherever they're tested, some insurance company might do well to sell anti-missile insurance to those in line of fire . . . Plans for inertial guidance in airliners and FBM-launching submarines contrast with German use of inertial systems in WW I submarines . . . Russia's studying compatabilities of isolated pairs of men and women in arctic experiments--Adamsky ee Evesky on Mars maybe? Dr. H. C. Urey wants to chip study chunks off the moon with nuclear warheaded missiles . . . Smithsonian Astrophysical's Dr. T. E. Sterne figures life of 200-800-mile high satellite at nine years . . . If he gets job here, Dr. Hermann Oberth may cancel his return to Germany . . . Add Danes and Norwegians (but not m/r's exec-ed.) to those taking missile courses at Huntsville . . . Residents of San Fernando valley have timed Rocketdyne engine tests up to two minutes . . . To the right: One way to get ultra-long burning times for solid propellants in minimum length . . .

UAP-built

heat exchanger, chassis-case assembly for compact pressurized airborne electronics*

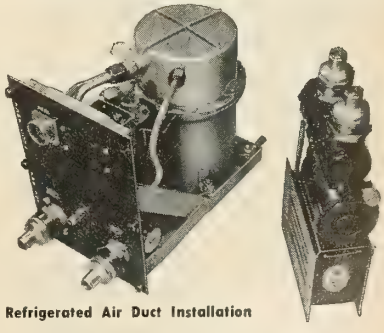
AIR TO AIR HEAT EXCHANGER. ELECTRONIC EQUIPMENT APPLICATIONS.

COLD PLATE FOR MOUNTING IN "BLACK BOX" WHICH HOUSES PRINTED CIRCUIT ASSEMBLIES: 1 AIR PASSAGE.



COLD PLATE: 3 AIR CIRCUITS: "BLACK BOX" ENCLOSED.

UAP dip-brazed heat exchanger is an integral part of the electronic components, chassis and principal structural member. All electronic components are mounted to the heat exchanger. Some assemblies dissipate heat from their surfaces to internal air circulated by a blower through the heat exchanger. Others function as a "cold plate" by dissipating heat through their mountings by direct conduction to the cooling air flow. Ram air or refrigerated air may be used for cooling. The heat exchanger—electronic assembly may be removed from the case as a unit for ease of servicing.



**Unit shown designed by Ohio State University Research Foundation —Air Force Cooling Study Project, W. Robinson, Supervisor.*

For information concerning watt dissipation, and other types of UAP cold plates call or write the nearest UAP Contractual Engineering Office:

PROPELLANT PROBLEMS?

SOLID PROPELLANTS MAY BE THE ANSWER! Solid propellants are simple to handle and operate in the field . . . will not evaporate, slosh or spill . . . and many solids are non-corrosive — give off no toxic fumes.

Phillips solid propellants work efficiently and reliably over very wide temperatures and pressures . . . are highly stable . . . have shelf life of years . . . afford maximum pre-flight, inflight and tactical reliability . . . burn smoothly . . . are economical.

Phillips can also supply solids with non-corrosive exhaust gas . . . low flame temperature . . . very low explosive sensitivity.

Phillips propellants are proved performers . . . let Phillips give you SOLID answers to your propulsion problems.

INDUSTRY SPOTLIGHT

By Norman L. Baker

Thiokol Geared for Solid Propellant Business Boom

ELKTON, MD.—The Thiokol Chemical Corp. may well play the lead role in the military planners increasing emphasis on solid propellants for missile propulsion units of the future. The list of the nation's operational missiles gives Thiokol an impressive lead as supplier of solid power plants.

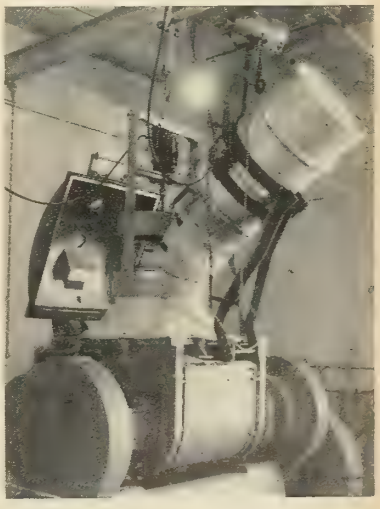
Lockheed apparently has released a contract to Thiokol for the initial testing of the powerplant for the Navy's Fleet Ballistic Missile, *Polaris*. Largest solid propellant missile officially revealed the *Polaris* will have a thrust of about 300,000 lbs. Reportedly Thiokol was selected for the testing phase of the *Polaris* motor development because of its advanced state of the art in developing large high-thrust solid propellants. This further indicates that Thiokol has been pioneering work in the high-thrust field for some time.

Significant is the fact that this work may have stemmed from the *Big "B"* ballistic missile program (m/r July 57, p. 48). Reported to be a 2000-mile Army missile powered by a Thiokol solid propellant motor its thrust rating would be comparable to the *Polaris* propulsion unit. A companion project, *Little "B"*, 750-mile ballistic missile, also will rely on Thiokol for powerplant development.

First flights under the Air Force Office of Scientific Research space program, Project *Far Side*, scheduled to begin this fall, will utilize a multistage solid-propellant rocket configuration. The motors, classed as off-the-shelf units, will be provided by Thiokol and Grand Central. *Recruits* will form the four-barreled first stage. A single *Recruit* will make up the second stage. Third and fourth stages will be modified *Loki* rockets. The fourth stage rocket will be nestled within the package of the four-rocket third stage. *Recruit* power plants are produced by Thiokol while the *Loki* is a development of Grand Central.

Thiokol's solid propellant development history can best be summed up in a list of existing operational missiles. The diversified program required to provide propulsion units for these varied weapon and research vehicles is quickly apparent. The motors range from boosters for the *Matador* and *Goose* to sustainer motors for *Falcon, Nike Hercules, Lacrosse, Terrapin, RV-A-10, Cajun, Recruit, Sergeant, Polaris, Big "B", Little "B"*, and the rocket motor for the new RESCU *Mark I* rocket ejection seat catapult.

Continuing research at Thiokol is conducted in the fields of propellant processing, manufacturing techniques, case-liner-propellant bonding, new material research for case fabrication and new propellant applications. Propulsion units developed at Thiokol range from "thimble-size to those limited only by practical mass-ratio values." Usually, as the size of the motors increase, the weight of the casing also increases until the mass-ratio value makes the design impractical. The search for new materials such as titanium and plastics is a continuing effort of the research team.



To the question of possible solid-propellant ICBMs, a company spokesman answered, "The development of a missile of the magnitude required for an ICBM is well within the realm of feasibility at the present time." This indicates a major reduction in the weight of the casing, a technical breakthrough which could very well mean the elimination of the size-limitation of solid rockets.

A major contribution to the field of solid propellants is the "case-lined cast-in-place" composite fuel mixture, a pioneering effort by the Thiokol Chemical Corp. With this system the composite fuel mixture is cast into place as a liquid and allowed to solidify. This permits bonding of the fuel charge directly to the internal walls of the pressure chamber. Insulation or cooling of the chamber casing and weight of supports is eliminated. Since the burning progresses from the interior toward the chamber wall, the chamber is protected from the heat of combustion by the propellant itself.

The elimination of the weight of inert components and utilization of a lighter, thinner engine chamber resulting in higher mass ratio values, makes the case-lined cast-in-place solid propellant adaptable to high performance systems. Thiokol's case-bonded composite-type propellants are readily adaptable for such an application. This is the determining factor for their apparent lead in the present emphasis on solid propellants for missile weapon systems.

The composite propellants produced by Thiokol are formulated principally of a polymer manufactured by Thiokol, an oxidizer salt, and a small percentage of chemical additives. The dry oxidizer and the polymer are dumped into a mixer by remote control. In the meantime a liquid layer of rubber is applied to the inner surface of the rocket casing and cured. This rubber acts as a bonding agent between the case and the propellant.

When the propellant has been thoroughly mixed it is discharged to a transfer can for the casting operation. The mixture is pressure-pumped from the transfer can into the rocket casings. The mixture is very viscous during this phase of the processing. A core, designed to form the internal configuration of the burning surface, is inserted in the raw propellant. The package is then cured in an oven until the mixture

Dry oxidizer salt is mixed with a Thiokol polymer. Mixing operation is by remote control.

CENTURY MODEL 409D RECORDING OSCILLOGRAPH

Numerous agencies engaged in the manufacture and evaluation of missiles have turned to the Century Model 409D Recording Oscillograph as a reliable means of collecting missile performance and control data.

On-board mounting eliminates the necessity for the costly and often not reliable RF link.

The ruggedness and reliability of this 12-channel oscillograph have been demonstrated many times. One agency reports having recovered 42 satisfactory record rolls out of 43 firings. Another, using special mounting configuration, reports recording at 60 G's without damage.

This 13 lb. instrument is compact enough to be installed in most missiles and all electrical connections including remote control are accomplished through a single multi-pin AN connector.

Wire, Write or Phone

CENTURY ELECTRONICS & INSTRUMENTS, INC.

1333 North Utica, Tulsa, Oklahoma

Circle No. 62 on Subscriber Service Card.

reaches the solid rubber state. The propellant is ready for trimming for the attachment of the rocket nozzle after removal of the core.

The discovery and development of Thiokol synthetic rubber by Dr. J. C. Patrick during the 20s led to the formation of the Thiokol Corp. in 1929. In 1941 a plant was installed at Trenton, N. J. for production of a solid polysulfide synthetic rubber and by 1945 this plant was marketing the basic component of Thiokol propellants, a polysulfide liquid polymer.

Thiokol currently operates six plants and laboratories: Main Offices, Trenton, N. J.; Redstone Division, Huntsville, Ala.; Elkton Division, Elkton, Md.; Longhorn Division, Marshall, Texas; Chemical Plant, Moss Point, Miss.; the Utah Division, Brigham City, Utah.

The Elkton Division was the first to undertake research and development on solid propellants and JATOs under contract with Army Ordnance. Main rocket activities were transferred to the Redstone Division in 1949. Research and development on industrial products are carried out at the main plant in Trenton. The facilities at Redstone and Elkton concentrate on rocket research for the Armed Forces. Although some production work is handled by Redstone and Elkton, the major production effort is at Longhorn.

The Utah Division, latest expansion achievement, recently began test operations. The new test stand at Utah will accommodate motors up to 12 feet in diameter and resist a two million pound load. The testing section is the first major portion of the facility while rocket motor mnaufacturing will commence this fall.

Thiokol employs over 2500 people, over 300 of whom are chemists, chemical engineers, mechanical engineers, mathematicians and physicists.

RMI Expands For Solid Propellants

Reaction Motors, Inc. has announced creation of a separate department for handling solid propellant fuels. Designated the Applications Engineering Department for Solid Propellant Rocket Power Plants, the new department will be headed by William M. Davidson and will be responsible for the development of new business in the field of solid propellants.

RMI's reorganization points out the growing trend in the industry toward the solid propellant fuels. This is the first time in RMI's history that a separate department for solid fuels has been set up, and it reflects the com-

pany's interest in this phase of rocket fuel development.

In the six months since the Institute of Aeronautical Sciences meeting heard speakers deplore the lack of exploitation in the solid propellant fuel field, there has been a distinct trend toward utilizing the fuels to a greater extent. Previous reluctance was laid to reliance on performance figures based on black gunpowder rockets. Judging by RMI's move and those of other producers of fuels, this is no longer true.

Mathieson Plans Propellant Expansion

Olin Mathieson Chemical Corp. has announced a four year expansion program to increase their facilities for developing and producing high energy, solid propellants. New R&D laboratories, pilot plants, and test and production facilities will be constructed at the company's Ordill works, near Marion, Ill.

The program at Ordill will involve the development of new propellants and new processes for the production of propellant grains for rocket engines. The company also plans to expand its development and production of gas generators for auxiliary power units on jet engines and missiles. In addition, it will cast double-base propellants which involve Mathieson's "ball powder" techniques and composite propellants for rocket engines in missiles.

These expansion programs are part of Mathieson's general plan to increase all their research, development and production in the broad field of fuels and propellants. including the new high energy chemical fuels. Two plants for the production of "zip" fuels are already under construction in Niagara Falls. The current program marks the company's first major effort in the field of solid fuels for rocket engines.

Rocketdyne Operates Vacuum Wind Tunnel

Rocketdyne engineers are now using a wind tunnel that pulls high speed air through a vacuum to simulate conditions at extremely high altitudes. The vacuum wind tunnel will be used in probing the performance of rocket engines and testing their components at these altitudes. The tunnel, located at the company's Los Angeles plant, is one of the first designed for high altitude rocket study.

In the tests, compressed air will be released in a supersonic rush through scale models of rocket engine thrust chambers resembling the narrow waist and flare of a hoop

HOW CALIDYNE CAN HELP PROTECT YOUR VIBRATION TEST INVESTMENT

CALIDYNE SYSTEMS ARE CUSTOM BUILT

For years, Calidyne has been building Vibration Test Systems to meet specific military, aircraft, automotive and industrial requirements. Most Systems have been custom-constructed for special applications. Although they were representative of the most modern equipment available at the time, it may now be to your advantage to modernize to meet the newer requirements of this fast-moving field.

HOW TO OUTWIT OBSOLESCENCE

Some of the older Calidyne Vibration Test Systems may have become obsolete to a point where they cannot be revamped to meet more modern requirements. With others, it is possible for us to up-grade the equipment so that its performance will compare favorably with any now being offered. In many cases this can be done without serious sacrifice of the original investment.

IT MAY PAY TO INVESTIGATE

When you want to investigate the possibility of bringing your Calidyne Vibration Test System up to date, get in touch with us here at Calidyne — we can quickly tell you what can be done. The telephone number is Winchester (Boston) 6-3810, or write:

skirt. To duplicate the upper atmosphere, the two-foot-wide testing chamber of the tunnel will be maintained under a partial vacuum adjusted to varying altitudes.

Final instrumentation check-out is made on rocket engine thrust chamber in test section.

Aerojet Sets Up Astronautics Lab

Aerojet-General Corp. has set up an Astronautics Research Laboratory to study advanced propulsion systems, astrophysical chemistry and materials. The laboratory's propulsion section expects to work on research involving ultra-high-energy chemical propellants, ion propulsion systems, gaseous free radical propulsion and nuclear plasma propulsion systems. In addition the lab will study all systems capable of high velocity extra-terrestrial flight. Director of the lab will be Y. C. Lee, Aerojet Director of Research, and Milton Farmer, Associate Director of Research.

Convair Occupies *Atlas* Production Plant

Convair-Astronautics has begun moving into its $40 million plant for the production of the *Atlas* ICBM. The plant, located on the northeastern outskirts of San Diego, is expected to be completely occupied by January. Moving plans and final construction plans were coordinated to afford a minimum of work interference on the missile, which is now in pilot production.

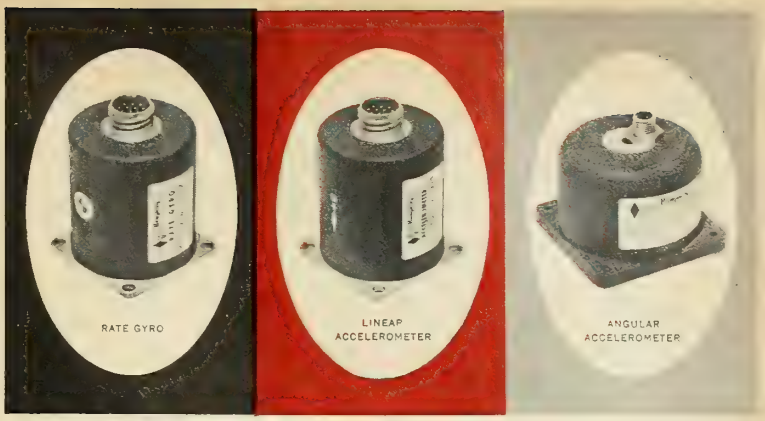
More than 7000 persons will be shifted to the plant. The million-square-foot plant will replace Convair's San Diego facilities as the headquarters of Convair's *Atlas* program.

The engineering lab will be the first section to be occupied, followed

by the office and reception center buildings. The factory building is scheduled for full use by mid-January. Total cost of the plant and its equipment will exceed $40 million, divided almost evenly between Convair and the Air Force. Convair is paying for the land, buildings and some of the equipment, with the AF providing most of the heavy equipment, including machine tools.

Chrysler Lists 1300 *Redstone* Subcontractors

The Army's prime contractor in the *Redstone* Ballistic Missile system, Chrysler corp. has compiled a list of vendors from whom purchases have been made during the program. The list is said to name over 1300 firms in the U.S. from whom purchases were made for the production and research and development phases only. There are a total of 1675 vendors in 34 states and the District of Columbia.



Chrysler's breakdown of the figures show that: 811 of the firms, or 48.4% employ less than 100 persons; 519, or 31% employ from 100 to 500; 121, or 7.2%, employ from 500 to 1000; and 224, or 13.4%, employ over 1000 persons. Since "small business" is usually defined as those employing under 500 persons, the actual number of such vendors is 1330 or 79.4%.

AC Spark Plug Receives *Thor* Guidance Contract

AC Spark Plug Division of General Motors has been awarded a $38-million contract from the Air Force for research, development and production of the inertial guidance system for the IRBM, *Thor*. Authority to begin work under the contract was given some months ago by the Ballistic Missiles Office, Air Materiel Command, which awarded the contract.

GE Gets Contract For Reentry Nose Cones

General Electric's Missile and Ordnance Systems Department in Philadelphia has been awarded a $158-million contract to develop nose cones for the *Atlas* ICBM and the *Thor* IRBM. The company's Nose Cone Section, under R. W. McFall, is staffed by 2000 people engaged in research, systems engineering, design engineering and development manufacturing of the nose cone.

Advanced Instrumentation by Humphrey

New production inertial sensing instruments for extra precision and reliability

Among the outstanding features of Humphrey's new inertial sensing instruments are: dry helium filled, hermetically sealed steel cases; standardized mountings for rate gyro and linear accelerometer; and choice of regular AN connector or new pigmy connector.

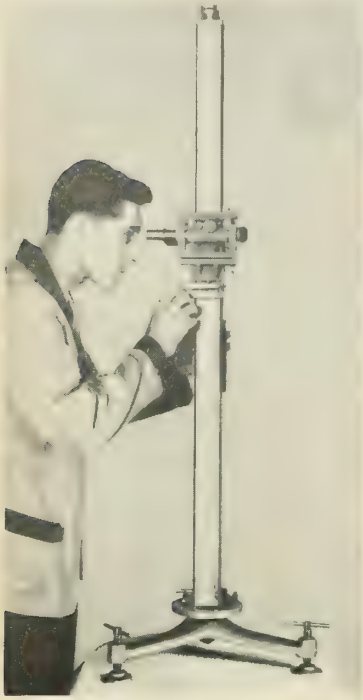
RATE GYRO is of new simplified design, with light-weight efficient motor, accurate trouble-free damping, and choice of inductive or potentiometer pick-off.

LINEAR ACCELEROMETER is of dual contra-rotating mass design. It has practically zero sensitivity to cross acceleration and angular acceleration; ±symmetrical or asymmetrical ranges (0 to 1G) to (0 to 100G).

ANGULAR ACCELEROMETER is compactly designed with completely symmetrical inertial ring. Available ranges are from zero to ±½ rad/sec² to zero to 100 rad/sec.² Except in very low range, either potentiometer or inductive pick-off can be furnished. Performance for either instrumentation or control systems is excellent.

Rate Gyro—Model RG15-0102-1: New simplified design with light-weight efficient motor.

Linear Accelerometer—Model LA15-0501-1: Zero sensitivity to cross and angular acceleration.



Angular Accelerometer—Model AA01-0207-1: Excellent performance for instrumentation or control systems.

Optical instrumentation for accurate measurement of remote or inaccessible objects

Gaertner M901 General-purpose Cathetometer

CATHETOMETERS

Gaertner Cathetometers are designed for accurate measurement of vertical distances or displacements. They are ideally suited for measuring where the object or action is remote or not accessible by ordinary means. Gaertner produces a wide variety of precision-constructed cathetometers to meet your individual requirements.

- **General-purpose Cathetometers**—These combine a high degree of accuracy with a maximum of convenience. Range 100 cm, focusing range 60 cm to infinity.
- **Precision Cathetometers**—For maximum accuracy and rigidity. Readings directly to 1 micron.
- **Micrometer Slide Cathetometers**—For precise measurement of short vertical distances. Range up to 4" or 100 mm. With telemicroscope, focusing range 12 cm to infinity.
- **Co-ordinate Cathetometers** — Permit making precise co-ordinate measurements on objects in a vertical plane. Focusing range 9" to infinity. Co-ordinate measuring range up to 24"x42".

West Coast Industry

By Fred S. Hunter

"First *Atlas* Ends in Failure" is the way the headline read in a widely-circulated national magazine. Well now, let's see! What, actually, constitutes "failure" in the test firing of the prototype of a new missile? How do you define it? Matter of fact, if you learn anything at all from the test firing of an experimental missile, can you call it a failure?

If something starts to go wrong on the first flight—or any test flight—of a manned aircraft, there's a pilot aboard to bring the airplane back to the hangar. Occasionally, a test pilot has to bail out, but normally he's able to return to base and continue the test program with the same airplane after fixes are accomplished. By contrast, if a missile starts to wobble, there's no alternative but to blow it up. You don't get to bring it back and use it again.

Where do you draw the line of "failure." We're reminded of the news writer who coined the phrase "*Snark*-infested waters" in describing Northrop's troubles with early XSM-62s in Florida. Northrop lost 13 experimental *Snarks* in these early tests. Now, successful *Snark* flights have become commonplace over a 2000-mile range in the Atlantic. The missile's reliability is one of its stronger points. How did Northrop accomplish this? Through the things it learned from the 13 losers. Would you say they were failures?

•

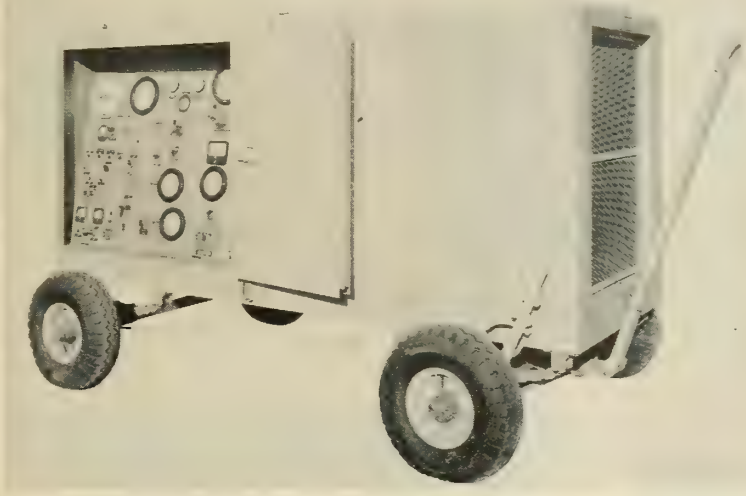
With the Air Force dropping North American's *Navaho*, what happens now to Wright Aero's ramjet engines? The *Navaho* was the only vehicle for which these particular engines were scheduled. But not many ramjets are in the works and the Air Force might consider an R&D contract for continued development advisable. Moreover, the Wright engines are big ones—48 inches as compared to 28 inches for the engine developed by Marquardt for the *Bomarc*. The Wright ramjets never reached flight test in the *Navaho*. It is understood that in one XSM-64 test, they were ignited momentarily at about Mach 1.5, but this wasn't fast enough to keep them going.

•

North American's new general office building in El Segundo is on the route over which Northrop trucks *Snarks* from Hawthorne to the Los Angeles International Airport for loading on Air Force C-124s, and all Lee Atwood and Larry Waite have to do is look out the windows to count their competitor's deliveries.

•

Air Force's announcement that General Electric's $158-Million nose cone contract covers both the *Atlas* and *Thor* missiles would seem to be fair evidence that the Douglas IRBM is still in business and should set at rest rumors that it's shaky. Avco's contract for the nose cone of the *Titan* came to $111 million. It doesn't necessarily follow that the same dollar amount of GE's contract applies to the *Atlas*—it might even be less—but it isn't unreasonable to use it as a measurement and this would leave $57 million of the GE order for the *Thor*. Whatever else may be said of the *Thor*, it certainly is the "quickie" of all the ballistic missiles. Douglas had the first article on the pad within one year's time.



•

Rocketdyne estimates two-way radio systems installed in eight trucks operating out of the Canoga Park plant enable present equipment and personnel to accomplish about a third again as much work.

NEW MISSILE PRODUCTS

MISSILE CHECK-OUT UNIT

A portable hydraulic power supply unit, designed by Haskel Engineering and Supply Company, serves as a source of high pressure hydraulic power for guided missiles requiring precise circuit check-out prior to launching. Designed for use with OS-45 high-temperature synthetic hydraulic fluid, the power supply contains two independent hydraulic circuits with a capacity of 20 gpm and providing pressures up to 5000 psi.

The unit is designed for remote control for personnel safety and its two circuits are both overheat and back-pressure controlled to shut off pressure and return in either circuit in case of excessive heat or back pressure. These controls also provide for dumping the pump output back into the tank and it is not possible to re-energize either circuit until the source of trouble has been corrected. Indicator lights are provided to locate the trouble.

The system features automatic pre-fill and bleed of the hydraulic circuits and is provided with a nitrogen purge pressurization system to preclude the possibility of contaminating the fluid. An automatic control is provided for the air type heat exchanger to maintain proper fluid temperature. Flow indication, system selection, on and off operation and emergency shutdown can all be achieved remotely. The unit is mounted on roadable running gear using light-weight Air Force Arctic tires. The cooling system, electrical system and piping can be serviced from separate access doors.

Circle No. 220 on Subscriber Service Card.

COUNT RATEMETER

Nuclear Measurements Corp. has introduced its manual range changing linear

count ratemeter, model CRM-11. The instrument detects radioactivity sensed by GM, scintillation and proportional counting detectors. It is equipped with six linear scales, ranging from 0-300 C/M to 0-300,000 C/M. Dimensions are 22 x 15 x 10½ inches.

Circle No. 212 on Subscriber Service Card.

POWER AMPLIFIER

Rheem Electronics Division has introduced a new power amplifier for use

in airborne telemetering systems which is available in 17 configurations. Designated the REL-09 RF Power Amplifier, the unit is a single package containing volume, connectors, filament voltage and cathode bias, varied to extend the range of application. The product weighs 16 ounces.

Circle No. 214 on Subscriber Service Card.

INSULATING VARNISH

Lynn Engineering Co. is distributing an insulating varnish capable of withstanding temperatures from —55°C to 250°C, and which is unaffected by gasoline, oils (including ester oils), alcohol, jet fuels, moisture and fungus. Known as Ulti-Meg 110, the varnish is suited for use on high speed rotating machinery and to all types of equipment subject to severe vibration. The chemical reaction of the product is completed during the baking cycle, producing a molecule which is physically and chemically stable and retaining its insulating qualities indefinitely.

Circle No. 206 on Subscriber Service Card.

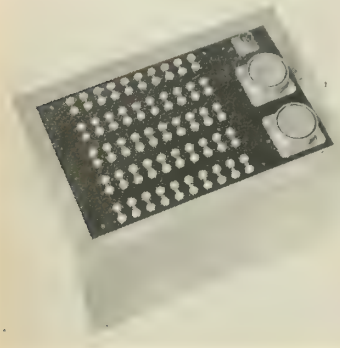
SMALL POWER UNIT

Rheem Electronics Division has developed a special miniature power supply for missile telemetry applications. It provides one unregulated high voltage output, one regulated HV output and a 6.3 volt heater supply. The unit is constructed for maximum reliability under environmental extremes.

Circle No. 204 on Subscriber Service Card.

CERAMOPLASTIC RADOME

A new molding material for radome manufacture is being produced by Mycalex Corporation. Called "Supramica 555", the material withstands temperatures as high as 950°F. The ceramoplastic contains platelets of synthetic mica to act as "crack stoppers" holding the



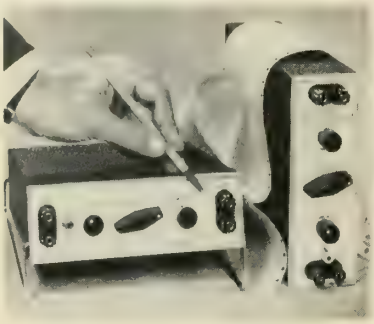
material together even when cracked. Molding tolerance in wall thickness of ±.005 "can be achieved, as well as machining tolerances of ±.001". The manufacturer anticipates that the thermal endurance of the material will be satisfactory at speeds as high as Mach 3.5.

Circle No. 203 on Subscriber Service Card.

THERMOCOUPLE JUNCTION

Pace Engineering Company is manufacturing its BRJ Series of bridge stabilized thermocouple reference junctions providing controlled temperature reference for multi-channel thermocouple measurements. The unit has precision beyond the capabilities of ice baths and cold junction compensators now in use. Up to 48 channels are available in cabinet or rack

mounted models, as well as three-wire junctions allowing a choice of thermocouple materials in each channel.



Long term temperature stability within 1/5°F is achieved with an integral resistance bridge temperature sensing system and magnetic-amplifier controlled heater. The reference temperature may be set to any specified level from 25° above ambient to 250°F and thermocouple tables are available for the standard reference temperature of 150°F.

Several models are offered with a variety of input arrangements and output coupling, thermocouple types and number of circuits. The reference junction is also furnished as part of an integrated control and calibration system for oscillograph recording. The unit's weight is 25 lbs., and it measures 10 x 10 x 15 inches.

Circle No. 218 on Subscriber Service Card.

TRANSISTOR AMPLIFIER

A completely transistorized electronically modulated DC amplifier for use with milliammeter recorders has been introduced by Texas Instruments Inc. The amplifier has a sensitivity range from 10

millivolts DC to 100 volts DC full scale in 12 ranges. Frequency response is up to 50 cps. Specifications on the model 301 are: 7½ x 10 x 2½ inches; 4¾ lbs.; input impedance is 2.5 megohms per volt; output impedance is 39 ohms and absolute accuracy is 2% of full scale.

Circle No. 200 on Subscriber Service Card.

BISTABLE DIODE

Shockley Semiconductor Laboratory has produced a new type diode. It is a low-power four-layer switching diode. The

two-terminal silicon device is capable of existing in either an open or high impedance state (1 to 100 megohms) or a closed or low impedance state (1 to 10 megohms). The diode is switched from one state to the other by controlling voltage and current values.

Typical value ranges are: firing voltage ranges from 20 to 60 volts; holding currents of 25 ma or somewhat less, at

new Zytel wire clamp cuts weight in planes and missiles

This unique wiring clamp weighs only 0.001 lbs. for 3/16" capacity handling 58,000 circular mils . . . only 0.052 lbs. for 2-1/2" capacity handling 8,570,000 mils. It resists fatigue in any position, and withstands loadings up to 50 g's. Easy installation—place wire bundle between U-shaped horns; push down the keeper—it locks, with permanent holding power. Sizes range from 3/16" to 2-1/2" across the horns.

REDESIGNED PREAMPLIFIER

A new weatherproofed and pressurized preamplifier design is announced

by Nems-Clarke, Inc., for use with telemetering receivers. The company says line losses as high as 6 db will not decrease the sensitivity of the receiving system by more than a few tenths of a db. The pass band has a uniform response of 3 db over a frequency range of 215-245 mc. The unit has a self contained power supply controlled from a 1¾" power control panel mountable in a relay rack with other receiving equipment. Similar units are available in the frequency range 225-260 mc.

Circle No. 210 on Subscriber Service Card.

WAVEGUIDE PRESSURE WINDOW

A new waveguide pressure window for half-X waveguide applications has

been developed by Microwave Associates. The window (MA-1339) covers the frequency range 9.5 to 10.1 kmc with maximum VSWR of 1.10 at the band edges. Resonant frequency is 9800 mc. It is used in .2 x .9 ID waveguide applications. Maximum power rating is 20 kw. Maximum pressure handling capability is 45 lbs. on the glassed side of the window and 30 psi on the opposite side. Window construction is of kovar and glass.

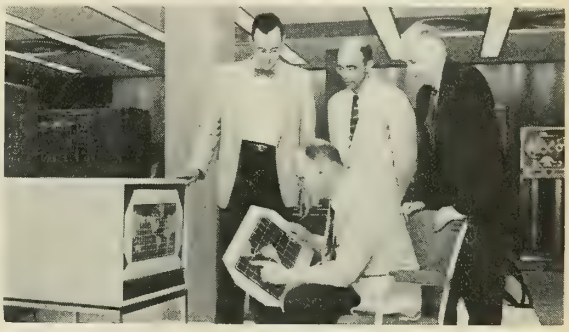
Dr. Joachim W. Muehlner has been appointed a consulting scientist in Lockheed Missile Systems Div.'s research and development branch at Palo Alto. **Dr. Muehlner** was technical director of the range instrumentation development division, Army Ordnance, at White Sands Proving Ground for more than five years. before joining Lockheed.

J. Y. Cunningham will head the new Missile Development Division organization at North American Aviation, which has just been separated from the Los Angeles Division. Other appointments in the new division are **R. M. Stronks,** manufacturing supt.; **Fred Burry,** general supv. of manufacturing services; **Harry Armour,** general supv. of missile planning; **D. F. Ziegler,** general supv. of missile tooling.

The new development planning staff at Fairchild Guided Missiles Division will be headed by **Harry Iddings** who was formerly associated with Cornell Aeronautical Laboratory.

Albert E. Schwerin, manager of Flight Test Engineering for General Electric's missile and ordnance systems department, has been assigned to the Air Force's Missile Test Center. He will head up his department's test activity at Patrick Air Force Base.

Lt. General Laurence C. Craigie (USAF, ret) has been elected to the Board of Directors of the Associated Missile Products Corp. **T. Rogers McNamara,** of Hughes Aircraft Co., has been appointed accounting manager of the corporation.



Dr. Michael Markels, Jr., formerly manager of heat transfer operations, Columbia University Heat Transfer Research facility, has been appointed to head Atlantic Research Corp.'s nuclear activities.

Willem Schaafsma has been named director of projects for the Grand Central Rocket Co. **Stanley Waxman,** former director of R & D, succeeds Schaafsma as director of engineering and research.

Wilfred E. Walton, formerly with General Electric, has been appointed director of engineering at American Machine & Foundry Co.'s Rochester Division.

Minitrack equipment for station No. 1 and a VANGUARD model are inspected by (left to right): Dr. J. P. Hagen, Project VANGUARD Dir.; A. E. Abel, Gen. Mgr. Bendix Radio Div.; J. T. Mengel, Chief, Tracking and Guidance, NRL.; Capt. P. H. Horn, Dir. NRL. Vans equipped by Bendix are heading for S. American Minitrack station sites.

Naval Research Lab. scientists examining a map overlay on which the IBM 780 cathode ray tube output display will trace earth satellite's path. Left to right: Dr. J. W. Siry; Dr. Paul Herget; H. Chrisman; J. J. Fleming. Herget is in charge of computation at VANGUARD Computing Center installed by IBM in Washington, D. C.

Above, Robert Edwards, newly appointed Bus. Mgr., Cook Research Lab., Cook Electric Co. Below is D. A. Bair, Mgr., Reliability Test Section, Cook's Inland Testing Lab., a multi-million facility to include world's largest (100,000 curies) gamma radiation source.

Adm. John H. Sides, deputy to the special asst. to the Secretary of Defense for guided missiles, will assume the rank of vice admiral and report as director, weapons system evaluation group, Department of Defense, on August 1.

Edward C. Wagner has been appointed to the post of assistant to the vice president for engineering, Ford Instrument Co., Division of Sperry Rand Corp.

Max Moore has been appointed chief engineer for the Precision Potentiometer Division of General Controls Co.

E. Douglas Reddan and Norman C. Anderson have been elected president and vice president respectively of Infrared Industies, Inc.

George S. Schairer has been appointed director of research for Boeing Airplane Company. He was formerly chief engineer of the Seattle division.

Jack E. Shuck, formerly a colonel in the Air Force's Air Materiel command, has been appointed a staff scientist on the Product Planning Staff of Lockheed Missile Systems Div.

Charles L. Backus, Jr., has been appointed manager of the Dayton office of Autonetics, a division of North American Aviation, Inc.

S. G. Gregory has been named for the newly created position of director of personnel services for Borg-Warner Corp.

Willis M. Hawkins, asst. gen. mgr. of Lockheed's Missile Systems Div., has been appointed a member of the U.S. Army Scientific Advisory panel.

Dr. Jacob L. Zar, the Guided Missiles Div. of Republic Aviation Corp., has been appointed director of engineering by Airborne Accessories Corp.

Robert J. Mill has been named manufacturing mgr. of Aerojet-General Corp.'s Liquid Rocket Plant at Sacramento. **Y. C. Lee** has been appointed director of research and planning for Aerojet's Liquid Engine Div.

Convair Division of General Dynamics Corp. has announced the following new assignments: **William C. Dietz,** chief of B-58 project; **Norm H. Simpson,** senior project engineer; **Don R. Kirk,** senior project engineer; **Robert W. Moller,** asst. mgr. of B-58 flight test program; **J. F. Robinson,** chief of engineering test laboratories; **R. P. Scott,** chief of engineering flight test; **William H. Crow** and **J. C. Thurmond,** asst. chief design engineers.

Reginald R. Kearton, formerly director of nuclear projects for Lockheed's Georgia Div., has been named director of the new sales branch of company's Missile Systems Div. at Sunnyvale.

James R. Merrill has been named mgr. of Raytheon Manufacturing Co.'s Santa Barbara (Calif.) laboratory, suceeding Harold E. Beveridge, resigned.

John E. Ranks, who served as a missile test officer at sea and as officer-in-charge of the Officers Electronic School, Treasure Island, Calif. during the Korean war, has been appointed mgr. of the Small Systems Dept.'s product engineering section at ElectroData Div. of Burroughs Corp.

Dr. John W. Bond, Jr., has been appointed chief of the physics group at Convair-San Diego.

Edward E. Slowter has been elected vice president of Battelle Memorial Institute, Columbus, O.

Rheem Manufacturing Co.'s new Aircraft Div. has announced three key ap-

pointments: **Glen S. Gipson,** western district sales mgr. with hq. at Downey, Calif.; **P. J. Raferty,** district representaitve in Chicago; **V. E. Selvig,** legal advisor.

The following management changes are announced by Olin Mathieson Chemical Corp.: **John M. Olin,** chm. of financial and operating policy committee as well as chm. of the exec. committee; **Thomas S. Nichols,** chm. of board of directors; **Stanley de J. Osborne,** president of the corporation.

Robert Lee Baddorf has been appointed chief engineer of Topp Manufacturing Co.

Wade Wolfe, Jr., has been named technical liaison mgr. in the construction engineering dept. of Olin Mathieson Chemical Corp.'s high energy fuels organization.

Richard E. Welch, vice president and treasurer of W. M. Welch Mfg. Co., Chicago, was elected president of the Scientific Apparatus Makers Assn.

Ralph Carlisle Smith, asst. director of Los Alamos Scientific Laboratory, has been appointed assistant to the president of the Nuclear Products-Erco Div., ACF Industries, Inc.

Edmund B. Parke has been named director of Production Div. at Reaction Motors, Inc.

Baboo Ram Teree has been elected vice president—engineering and manufacturing of Greer Hydraulics, Inc.

John Carter, a vice president of Corning Glass Works, has been elected president of Fairchild Camera and Instrument Corp.

J. M. Miller has been placed in charge of all design activity on equipment for the Talos missile and **E. F. Lapman,** now chief electronics engineer, has the responsibility for design for all electronic systems, Products Div., Bendix Aviation Corp.

J. E. Schaefer of Wichita has been elected vice chairman of Boeing Airplane Co.

Dr. Seymour B. Cohn has been appointed mgr. of Stanford Research Institute's Antenna Systems Laboratory.

Dr. John P. Nash has been appointed mgr. of the information processing division, Lockheed Missile Systems Div.'s research and development branch.

David E. Shonerd has been named president of Era Engineering, Inc.; **Harold D. Hutchinson,** vice president; **Mary F. Cramer,** treasurer; and **Glendon Tremaine,** secretary.

Gladyln H. Putt has been named executive assistant to L. Eugene Root, vice president and gen. mgr. of Lockheed's Missile Systems Division. Putt was formerly with RAND Corp. as executive assistant to the president.

Sterling C. Spielman is the new director of engineering at Philco Corp.'s Government and Industrial Division. He was previously director of electronic engineering.

I. J. Hammill has been appointed as executive vice president and managing director of Walter Kidde & Co. of Canada Ltd. He succeeds C. K. McLeod who becomes chairman of the board.

Honeywell's "balanced" diversity brings you more opportunities

This Supervisory DataCenter, which enables one man in one location to control an entire air conditioning system for a large building, is just one of Honeywell's advanced automatic control products for civilian use. Honeywell also develops and produces advanced control devices and systems for the home, farm, industrial processing and factory automation.

Honeywell's Ordnance Division develops and produces such military products as: warheads; infrared systems and components; transistorized converters, inverters and rectifiers; test, checkout and training devices; thermal batteries; electronic fuzing; sonar systems; fire control systems and stabilized platforms.

HONEYWELL, world leader in automatic controls, is following a planned development program which is soundly balanced between civilian and government contracts. This program is giving Honeywell the fastest growth rate in its seventy year history. Earnings have more than doubled in the last five years. The engineering force has increased over 100%.

And Honeywell's exciting growth is continuing. To sustain it, we need skilled DEVELOPMENT, DESIGN, PRODUCTION AND ANALYSIS ENGINEERS to work on the types of products listed above.

You will receive the opportunity to grow with Honeywell, the fastest growing company in America's fastest growing major industry—the Electrical-Electronics industry. You'll work in a small group, your accomplishments will be quickly recognized, rapidly rewarded. You start with a first-rate salary, advance quickly from there. Start today.

Sperry Rand Corp. Enlarges Salt Lake Lab

Sperry Rand Corporation will add a 100,000 square foot unit to its Salt Lake City Engineering Laboratory, thus tripling the size of its Utah facility. The new unit will add 90,000 square feet of manufacturing space, 5000 square feet of environmental testing space, and 5000 square feet of utility space to the north side of Sperry's present lab.

It is reliably reported that Sperry will manufacture the Thiokol solid-propellant-powered *Sergeant* missile at the facility.

Honeywell Gets Missiles Repair Contract

New military emphasis on maintenance of missile electronic equipment has resulted in the instigation of a contract repairs program by the Aeronautical Division of Minneapolis-Honeywell Regulator Co. Named to head the new program is George P. Smith, with John S. Wagner administering the integration of production facilities and possibly reorganizing plant operations.

Travelling at Mach 10 it would take about 7 months to reach Mars . . . but we understand that the Martians are prejudiced against hiring foreign engineers, so why bother. Here at ASCOP there are more opportunities for capable men than there are miles to Mars. If you can qualify in the fields listed below, call or write our Technical Personnel Manager.

Lockheed Builds New R&D Center

Lockheed's Missile Systems Division has begun construction on a new lab at its Palo Alto R&D Center, increasing the center's facilities to 218,000 square feet. The new lab is the fourth 51,000 square foot lab to be built at the Palo Alto activity. This latest addition brings the division's Bay area facilities to a total of 583,000 square feet now in use or under construction. Its Van Nuys plant, with 475,000 square feet, raises the Missile Division's total plant space to more than a million square feet.

The new lab, which will be begun at about the time the third lab in the series is occupied, is next to the last in the building program of the division's 22-acre Stanford Park industrial site. Construction will be of the concrete tilt-up type reinforced with steel.

Ryan Opens New R&D Center

Ryan Aeronautical Co. is centering all its engineering, research and development work under one roof at its new half-million dollar Engineering and Research Center in San Diego. The new center includes an environmental test laboratory, a self-contained research machine shop and the main engineering laboratory.

The new center will be used for ground testing components of high-speed aircraft and missiles. While finishing touches are being put on the two-story building, installation of special equipment is commencing. The equipment in the center includes devices to simulate extreme shock, vibration, acceleration, temperature, altitude, humidity and radio interference.

RIAS Awarded Satellite Contract

RIAS, Inc., has been awarded an earth satellite contract by the National Science Foundation, in collaboration with the Franklin Institute, to carry out measurement of the heavy cosmic ray flux. The experiment requires light-weight, shock-resistant, high performance equipment that RIAS is developing with the Martin Co.

The two companies have succeeded in developing a transistorized pre-amplifier to amplify the impulses of an ionization chamber that will detect the cosmic rays in outer space.

DATA PROCESSING SPECIALISTS!

Get in now—at the beginning of the new era in missiles!

When you join Telecomputing's Engineering Services Division, you will be given full scope to allow you to grow . . . your talents will be used to the fullest . . . recognition and rewards will be yours as a matter of course.

Engineering services is a member of an integrated five-company missile systems corporation which designs and manufactures its own data-processing equipment. Our efforts are directed toward the "systems concept." We are engaged in the reduction of large amounts of flight test data being generated by the daily missile firings on the integrated Holloman-White Sands range.

MECHANICAL DESIGN ENGINEERS

Exhaust Nozzle with diameter no greater than a fire bucket's?

...Tail Pipe no longer than a bat?

ME's accustomed to conventionally sized aircraft gas turbine components find a challenge to their ingenuity in scaling down AGT parts full orders of magnitude when they come to SAED (Small Aircraft Engine Department of General Electric).

And miniaturization isn't the whole story either. Many other tough design problems cropped up in producing the T58 Turboshaft — many are involved in developing the T64 convertible gas turbine and other small, advanced power plants.

Design engineers who want to advance in their specialties and associate themselves with a leader in this growing field are invited to investigate new openings at the Small Aircraft Engine Dept.

ALSO: Field & Flight Test Engineers will find openings at SAED's flight test center and at airframe manufacturers' locations, handling 50-150 hour qualification tests, training of customer personnel, etc.

Please write in confidence to Roger Hawk

BENDIX OFFERS THE FINEST GUIDED MISSILE OPPORTUNITIES IN THE MIDDLE WEST

It isn't often that you can combine ideal living conditions with outstanding advancement opportunities. At Bendix Guided Missiles we sincerely believe we can offer you both.

We are sure that you would enjoy living in an attractive community convenient to metropolitan centers and recreational areas.

And, we are equally confident that as prime contractor for the important and successful Talos Missile, no one can offer a greater variety of interesting and challenging job opportunities in the guided missile field.

If you would like proof of these strong statements, why not fill out the coupon and send for a copy of our thirty-six-page booklet "Your Future in Guided Missiles". It not only gives a detailed story of guided missile operations, but it also presents interesting facts about living conditions in the area, the many special employee benefits, and the wide range of specific job opportunities we have to offer.

Send for your copy of "Your Future in Guided Missiles" today.

Bendix — prime contractor for the TALOS MISSILE

Bendix Products Division—Missiles
412 J, Bendix Drive, South Bend, Indiana
Gentlemen: I would like more information concerning opportunities in guided missiles. Please send me the booklet "Your Future In Guided Missiles".

CITY_____ STATE_____

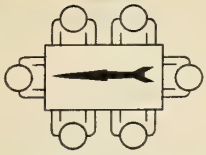
Navy Opens *Vanguard* Computing Center

High-speed electronic calculations at the *Vanguard* Computing Center, which the Navy opened on July 2, will predict future orbits of U.S. scientific satellites. The center will be operated for the Navy by IBM, which will use their 704 electronic data processing system. In conjunction with the 704, which will be magnetic-tape operated, IBM plans to utilize an IBM 780 Cathode Ray Tube Display Unit. This visual display unit will picture the 704's computations in the form of graphs, geometric figures, engineering symbols or words and numbers. The display unit will actually picture a satellite's orbit.

W. R. Grace Co., Pechiney To Produce Silicon

The formation of a new U.S. company for the production of high-purity elemental silicon and other semi-conductors was announced in July by the W. R. Grace Co., of New York, and the French chemical and metallurgical firm of Pechiney. The two companies will combine their efforts in silicon production as they did in 1952 for the production of ammonia and urea in Memphis.

Cooper Development Will Enlarge Facilities



Cooper Development Corp. is doubling its plant facilities due to increased activity in the design and production of high-altitude research rocket devices, meteorological rockets, infrared equipment and special missile assemblies. The three way expansion program involves a new plant in Baldwin Park, Calif., a facility at Fontana, Calif., and a new addition at the main plant in Monrovia, Calif.

NEED AIR FORCE SALES?

I have open time as manufacturer's representative with the Air Force at Wright-Patterson in Missile Systems, Airframe and Engine Components, and Electronic Training Devices. Nine years of successful experience.

P. O. Box 624
Far Hills Branch Dayton 9, Ohio

Engineers:
What's your solution of effective handling of 50 complex projects simultaneously?

SEE HOW ARMA'S PROJECT TEAM SYSTEM BENEFITS THE INDIVIDUAL ENGINEER AND THE COMPANY

Science and technology are becoming increasingly complex. So also are the solutions to the advanced engineering problems which ARMA is called upon to resolve, such as developmental aspects of the Inertial Guidance System for ICBM Titan and the Fire Control System for B-52 tail defense.

To make sure that each project receives expert guidance at every phase—research, design, development—ARMA entrusts each engineering contract to a group of engineers known as a "Project Team."

Composed of key personnel drawn from the major departments of the Engineering Division, a Project Team must see its project through, from conception to completion. Each engineer represents his department and carries equal responsibility for the success of the operation.

To the Individual Engineer, the value of the system is immeasurable. He gains an overall view of company operations, diversifies his professional knowledge and acquires a specialist's know-how in his field.

If Professional Engineering of this Calibre is what you are looking for—and you have had 2 to 5 years experience in precision instrumentation or electronic devices and systems or inertial navigation systems—we will welcome your inquiries at ARMA.

Current openings are at all levels and in various phases of design, development, analysis, evaluation and test operations.

Please forward your confidential resume to Robert Burchell. No reference contact without your permission. Our reply will include two brochures with detailed information about ARMA and its location on suburban Long Island.

Technical Personnel Dept. M-674

DIVISION OF AMERICAN BOSCH ARMA CORPORATION

Roosevelt Field, Garden City, Long Island, N. Y.

ENGINEERS & SCIENTISTS

To Generate Practical Solutions to Pressing Problems

Republic Aviation's Development Staff has important openings for engineers capable of solving practical problems in:

AERODYNAMICS

FLIGHT DYNAMICS

THERMODYNAMICS

The work involves studies of performance, stability, control, flight loads, engine inlets and exits, and aerodynamic heating on atmospheric re-entry. The problems have direct application to vehicles and systems ranging from zero-velocity VTOL craft far into the hypersonic regime of ballistic and glide weapons.

Engineers with experience in solving intensely practical problems will find staff openings of exceptional reward, and opportunity for continued professional growth with the creators of the XF-103 and the F-105B Thunderchief . . . most powerful supersonic fighter-bomber . . . designed and built under the Weapons System Concept. Graduate engineers with various ranges of experience will discover work levels fitting their degree of training and ability.

Salaries are highly competitive. Benefits are broad and intelligent, and include opportunity for advanced academic work. Positions are on Long Island, choice among Atlantic coast locations for working, living, relaxing.

Send a comprehensive resume today to
Mr. George R. Hickman, Engineering Employment Manager
You will receive a prompt, personal reply.

NEW PRODUCT BRIEFS

TION MOTOR. Three phase, 200 , 400 cycle motor for intermit- ty. Unit is of internal planetary onstruction with output shaft of 200, 800, 4000, or 20,000 rpm. tios alterable to suit needs. Re- ¼ hp, rotor shaft on anti-fric- earings. Operates at ambient tures of —100°F to 200°F. n Bosch Arma Corp.
o. 223 on Subscriber Service Card.

SAL CUTTER. Tape-controlled tool cutting head can twist or ny degree during cutting. Stop- e cut or relocating the part is sary. Northrop Aircraft Co.
o. 224 on Subscriber Service Card.

BAND ABSORBER. Broadband ve absorbent material with a m reflection of 0.1% above 8400 ws accurate testing of systems Other absorbers available with characteristics at lower frequen- F. Goodrich Co.
o. 225 on Subscriber Service Card.

OVERTER SWITCH. Precision, nant inverter, available in 75 d variations for low-power and cuit uses. Wide variations in ratings, vibration and shock re- , and frequency ranges avail- ne Bristol Co.
o. 226 on Subscriber Service Card.

ATE INDICATOR. Provides ac- instantaneous readings for set- F hydraulic feeds on machine Unit gives feed-rate changes of d 0-50 ipm, with accuracy within Other scales available. Overall ¾ x 9⅝ x 4¾". National Auto- ool Co.
o. 227 on Subscriber Service Card.

OL ALLOY AVAILABLE. Soft ic alloy coupling high permeabil- high wear-resistance; contains egic elements. Available in strip as .025"; maximum permeability 0 to 120,000; coercive force is sted and Rockwell hardness is O. Hamilton Watch Co.
o. 228 on Subscriber Service Card.

CAL COOLANT. A chemical dielectric for airborne elec- equipment which remains pump- om —65°F to 400°F is available with "black-boxed" electronic Coolant is a silicate ester-based afe to handle and compatible most all structural and electronic ls. Monsanto Chemical Co.
o. 237 on Subscriber Service Card.

PNEUMATIC PRESSURE REDUCER. Miniature reducer with ¼" ports conforms to MIL-R-8572A; weighs 0.17 to 0.25 lbs. depending on spring. Available with or without relief valve and adaptable to hydraulic uses. Operating temperature range from —65°F to 225°F may be altered with internal design change. Pneu-Hydro Valve Corp.
Circle No. 230 on Subscriber Service Card.

EPOXY GLASS LAMINATES. Micaply epoxy glass laminates for printed circuitry are available in black material for uses requiring this type. Standard thicknesses include from 0.032" to 0.5". The laminates are available clad in copper or unclad. Units are also available with circuits flushed to surface of the material. Mica Corp.
Circle No. 231 on Subscriber Service Card.

STANDARD DATA ANALYZER. Developed by Control Instrument Co., this unit simulates and projects machine operations, using precision potentiometers to control programming. Each of three dial-potentiometers represents a different factor in selecting optimum machining conditions. Control Instrument Co.
Circle No. 232 on Subscriber Service Card.

BLAST GAGE. Microphones linear to a 200 db level vs. 0.0002 microbars for accurate reproduction of transient pressure waves without distortion are being produced which are capable of operating continuously at 160°F. Rise times on the order of 100 microseconds are measured, showing steepness of a wave front. Overall dimensions are 2⅜" x ⅝". Massa Laboratories.
Circle No. 233 on Subscriber Service Card.

TRANSISTORIZED CONVERTER. Power conversion unit weighing 1.06 lbs. and having a conversion ratio of 85%, with only about 2% drop in ratio at 185°F. and a ground support unit with 5 DC and 3 AC outputs and weighing 3700 lbs. are both being manufactured by Wincharger Corp.
Circle No. 235 on Subscriber Service Card.

FERRITE CIRCULATOR. A miniature ferrite phase differential circulator provides service as a duplexer and load isolator, functioning as a switching device between magnetron, receiver and antenna. The device gives sufficient insulation between the magnetron and RF energy reflected from line mismatches. Units are available in almost all waveguide sizes. Airtron, Inc.
Circle No. 236 on Subscriber Service Card.

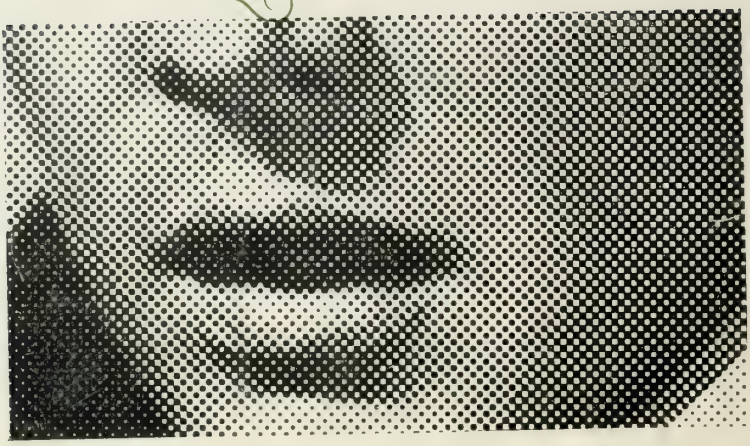
AIRBORNE SYSTEM CAPABILITY

The Research and Development group at Rheem Aircraft is currently engaged in the conception, evaluation and design of advanced airborne systems.

The wide scope and diversified capabilities of this group are evident in the list of current activities:

- DRONE SYSTEMS
- SMALL MISSILE SYSTEMS
- EXPLOSIVE and ORDNANCE DEVELOPMENT
- PROPULSION SYSTEM ANALYSIS

Advanced studies of future missile, aircraft and ordnance requirements are currently under way.



If you would like to join this group of technically capable personnel and participate in broad and diversified projects, submit a resume: Personnel Manager, Aircraft Division, Rheem Manufacturing Company.

All inquiries held strictly confidential.

Rheem

communication is a sometime thing

Lips encouraged to voice new theories helped make possible modern rocket power. Yet—for the sake of our nation's safety—our lips must remain sealed to our enemies.

RMI has long been known for its "open and shut" communication—for its encouragement of creative discussion not only within RMI but also with others who are working to advance America's cause . . . *and* for its constant vigil to protect America's secrets. For over a decade and a half, RMI engineers and scientists have been cooperating whole-heartedly with our nation's security program as they blaze new trails in developing and producing today's . . . and tomorrow's . . . powerplants.

Engineers, Scientists—Perhaps you, too, can work with America's *first* rocket family. You'll find the problems challenging, the rewards great.

MAGAZINE OF WORLD ASTRONAUTICS

AMERICAN AVIATION PUBLICATION

This Issue:

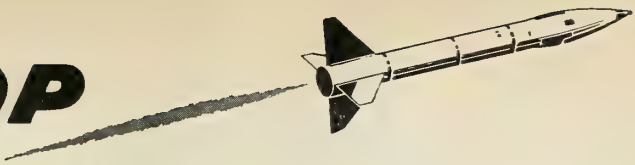
LIQUID ROCKET PROPELLANTS AND EXOTIC FUELS

Friendly Foe

When a new air defense missile is produced, its "kill accuracy" is theoretical until it is tested against a realistic target under operational conditions. The new, supersonic missile target, **USAF XQ-4,** is one of many "friendly foes" developed by Radioplane to simulate various air enemy threats.

Duplicating the performance and radar appearance of a supersonic, high-altitude bomber, the radar-controlled XQ-4 is designed to test the seek-and-kill ability of air defense systems and their missiles.

As major advancements have been made in U.S. Armed Forces air defense weapon systems, Radioplane has designed and developed targets compatible with the missions of these weapons. The XQ-4, for example, not only imitates invading bombers, but tallies up the score of hits and misses when fired upon.



Radioplane, the first to produce remotely controlled target aircraft, maintains dynamic research programs to seek low-cost solutions for tomorrow's defense problems.

ASCOP

records missile "history"

at giant new DATA CENTER

ASCOP M Series Ground Station at General Electric's Data Reduction Center

GENERAL ELECTRIC's new multi-million dollar Missile Data Processing Center — one of the nation's largest — is now engaged in advanced scientific computation and evaluation of missile flight tests.

This giant Philadelphia center contains the most advanced automatic data processing and handling equipment in use today. A completely integrated operation, it greatly facilitates the speed with which vital data can be made available for analysis.

Playing an important role in this strategic operation is the ASCOP PW Data Reduction System which includes monitoring facilities. An ASCOP Ground Station handles many channels of low frequency data . . . simultaneously reduces eighty-six data channels, held to a system accuracy well within 1%. This data is originally gathered in the missile by ASCOP airborne telemetering units.

The linearity and reliability of this ASCOP system is a major factor in the advanced performance of the entire installation. And, significantly, the modular-unit flexibility of ASCOP equipment made possible delivery of the system **months in advance** of the opening of the GE Data Center . . . one more reason why it will pay you to investigate ASCOP for your present and projected programs.

ASCOP M SERIES GROUND STATION

PLAYBACK AND MONITOR GROUP • DECOMMUTATOR AND TRANSLATOR GROUP

This ASCOP PW Ground Station is a complete "packaged" system for data processing. Eighty-six Channels may be reduced in real time from tape records. Utilization of zero and full scale sensitivity reference channels affords continuous automatic system calibration, avoiding frequent manual adjustment and the need for critical components. All channels may be visually monitored simultaneously. Easy access to slide mounted chassis is featured even during operation.

"QUICK LOOK"

ASCOP Monitor Console provides a means of rapid simultaneous inspection of all eighty-six channels. Can also be supplied with a Stripper Panel which makes possible the inspection of selective channels as desired. The ASCOP Monitor Console saves data reduction time and provides important maintenance advantages.

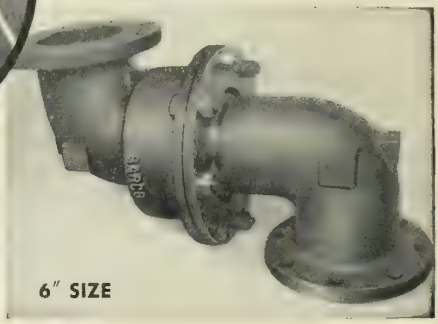
BARCO FLEXIBLE JOINTS

For Handling High Energy Fuels . . . .



. . . . . liquid oxygen, white fuming and red fuming nitric acid, and JP 3, 4, and 5 fuel

4" SIZE

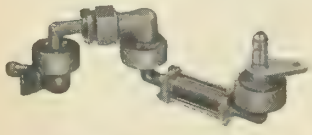
4" special stainless steel Barco Flexible Ball Joint for handling liquid oxygen.

6" SIZE

180° flanged 6" Barco Ball Joint for use in loading and unloading line handling liquid propellant.

-special designs for LOX and other Missile Fuels

Extensive design and manufacturing experience is yours to call upon at Barco for the handling of special liquid fuels in the aircraft, rocket, and missile industries:

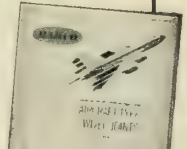


—Flexible Ball Joints for metal loading lines handling corrosive fluids.

—Special flexible joints with leakproof seals for conveying fluids at low temperatures down to −300°F. Also high temperature designs up to +1000°F.

—Special designs resistant to nuclear energy radiation.

Barco joints provide flexibility *unlimited* for piping and tubing. Our engineers will be glad to work with you on special problems and assist with recommendations.



Flexible Hydraulic Lines for Missiles, Aircraft

MISSILE LAUNCHER HYDRAULIC ASSEMBLY

Barco produces high pressure self-aligning swivel joint and tubing assemblies for hydraulic pressures to 4,000 psi, and higher. Also a wide selection of standard and special swivel joints and assemblies for launching and flight gear. Sizes ¼" to 1".

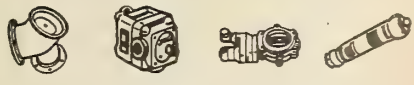
that's the word, sir...

Parker



Hydraulic and fluid system components

Parker *specializes* in hydraulic and fluid problems *as these problems apply to* ***your*** *SYSTEM.* This is called "Parker's system approach." What does it mean to you? Just this: Parker's leadership in experience and design is at your disposal to make sure that your fluid and hydraulic system components are exclusively for ***your*** system—*an integral phase of that system*—to make sure that the *whole* performs exactly to requirements—or *better!* Why not ask us how the Parker "system approach" can save you precious engineering lead time and effort?

let a Parker team help you!

The Parker Team provides specialized viewpoints to get the right answers. It's the first step in the "systems approach" . . . gives a Parker customer the plus value of leadership in experience, for today's *AND TOMORROW'S* fluid and hydraulic problems.

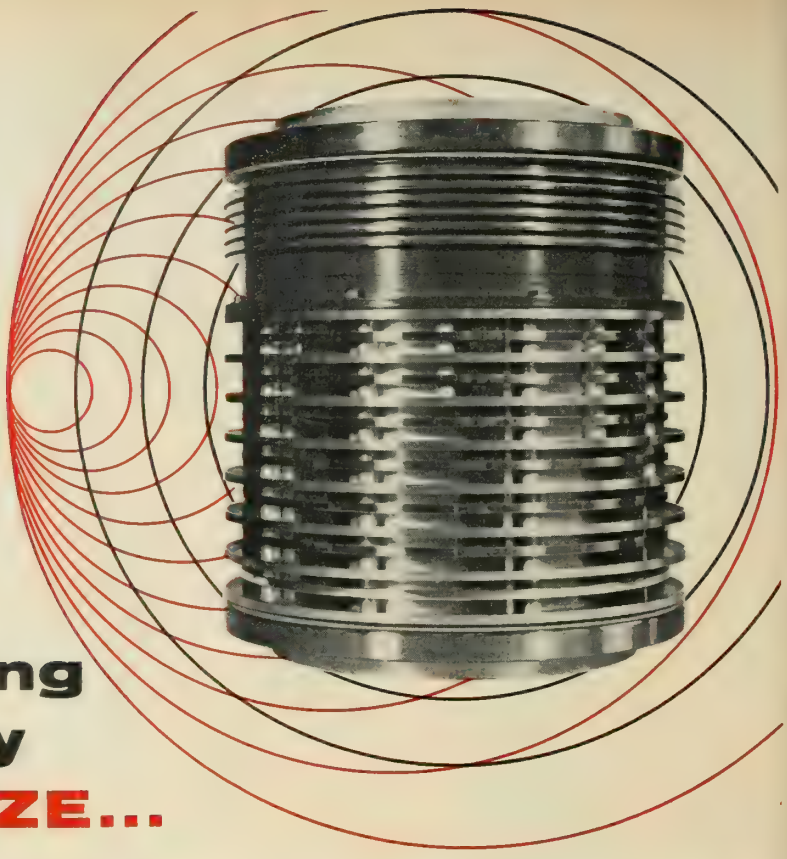
Model II B Accelerometer

INERTIAL GUIDANCE . . .

a Breakthrough by Bell Aircraft

The high precision, II B linear accelerometer, now in quantity production, is one of many examples of the recent dramatic progress of the *Avionics Division* of Bell Aircraft Corporation in the field of inertial instrumentation. With a range of ±25 g's and a frequency response of 0 to 350 cps, its performance is rated by leading authorities as exceeding all others now available.



As one comparatively small detail in Bell's overall inertial guidance program, the accelerometer is indicative of much broader more advanced accomplishments by Bell's team of instrumentation experts. This and their other successful developments . . . the knowledge they have gained in over 20 years of work on inertial components . . . are available to other missile and guidance system builders in advancing the frontiers of technological achievement. For information write: Sales Manager, *Avionics Division*,

Avco today

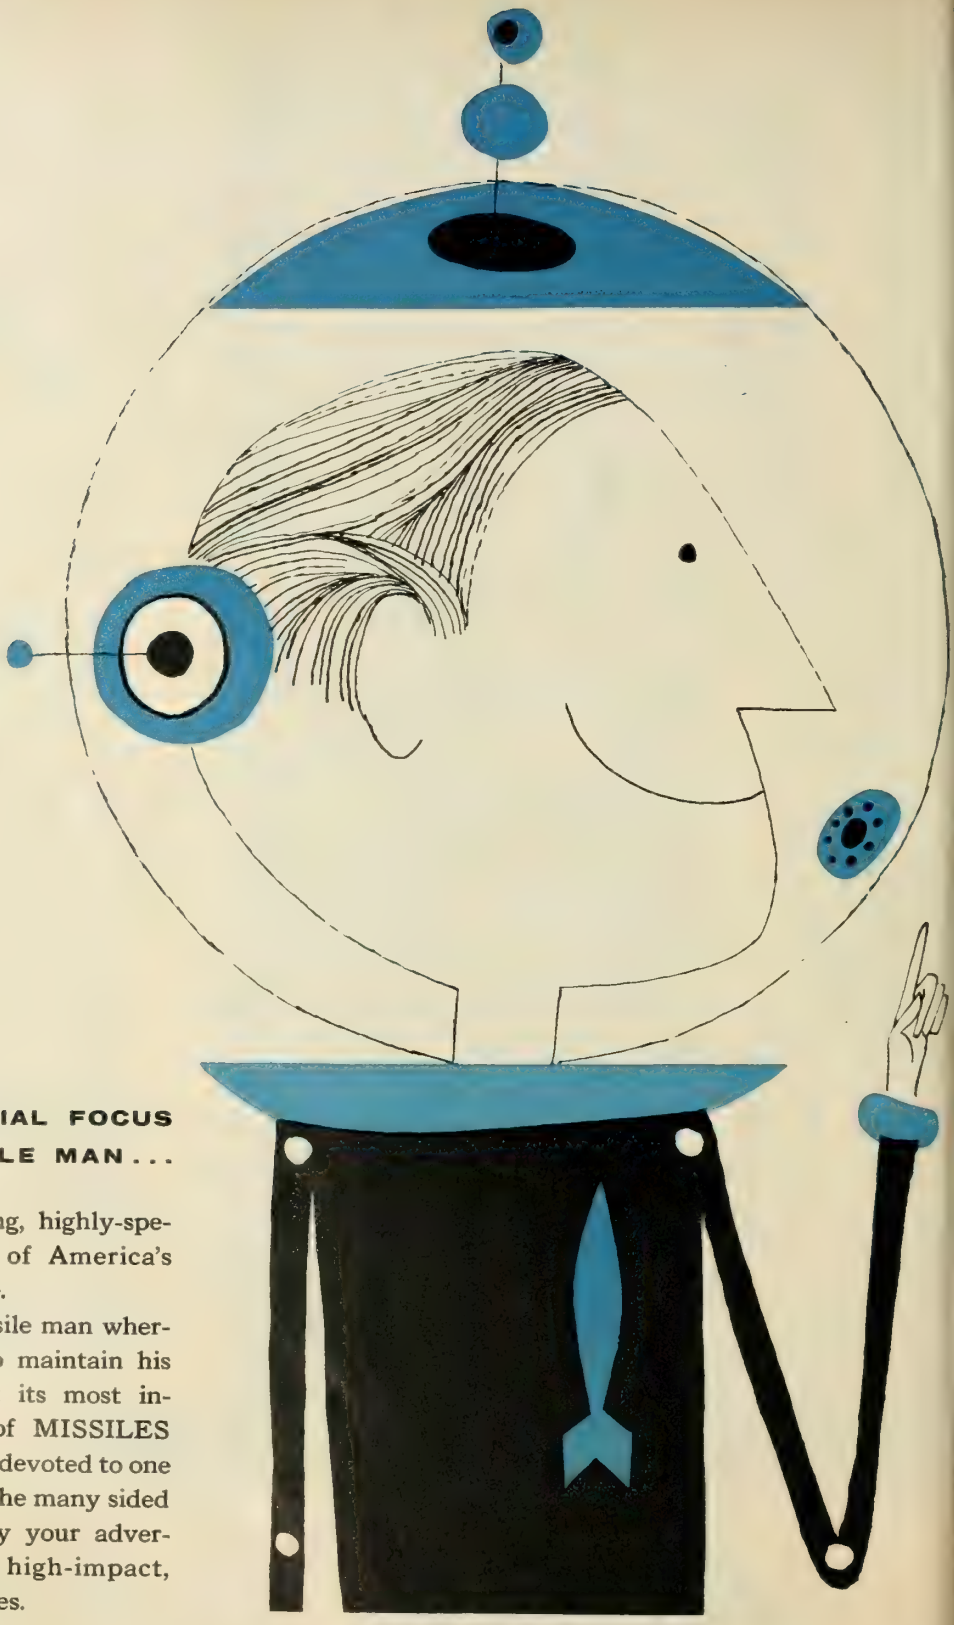
Avco makes the "business end" of the ICBM

How to keep the intercontinental ballistic nos cone from blazing into white heat and vaporizing completely, as it re-enters the earth's lower atmosphere, has been one of the biggest problems facing missile developers. Avco Research and Advanced Development scientist have solved this problem in the laboratory. With a device called a "shock tube," they hav simulated 18,000 mph speeds and 15,000 degre temperatures to study what happens to a missil during re-entry. They have produced re-entry information which has enabled Avco engineers to design and construct an experimental nose cone for the Air Force Titan missile. Another *breakthrough* by the Research and Advanced Development Division of Avco! What is Avco'

THIS IS AVCO

Avco today is a diversified organization whose products include aircraft power plants and structures, electronics for defense and industry, and specialized home and farm equipment. Avco's divisions and subsidiaries are:

Crosley—electronics and aircraft structures . . . American Kitchens . . . Lycoming—reciprocating engines and gas turbines . . . New Idea and Ezee Flow—specialized farm equipment . . . Research and Advanced Development . . . Crosley Broadcasting Corporation . . . Moffats, Ltd. (Canada)—commercial gas and heating equipment.



Scientists interested in unusual opportunities for advancement can grow with Avco.

For a copy of this Pursell illustration in full color, suitable for framing, write to "Art Reprints Department" at Avco Manufacturing Corporation, 420 Lexington Avenue, New York, N.Y.

Let's Call In General Yates!

Cutbacks in military buying and manpower are under way, with more coming. Arms cuts of major size are already in effect. Defense spending will be cut from $40.2 billion to $38 billion or less. Actually, this may be interpreted as an avalanche-type cutback, and it will be felt. The Army will feel it in terms of less manpower; the Navy must mothball 60 major combat ships; the Air Force will stretch out and cut orders for planes.

Businesswise, our missile programs will not suffer much, in spite of such drastic cancellations as the death of the *Navaho.* Those 12,000 or more people weren't all working on the *Navaho,* were they? Furthermore, North American's facilities and engineering capabilities represent such an asset to the nation's missile knowhow, that North American already is back in business. However, current defense cutbacks will mean a streamlining of the missile program. This isn't to say that there will be a cutback in terms of ultimate missile striking powers. But the White House expects more and better missiles for less money. This makes sense. We are beginning to learn.

Nevertheless, it remains a fact that the missile business is still in quite a messy state. It is rather disorganized. Very few people know very much about where we're going, nor the best way to go about getting there. That's why the White House asked for action. Reportedly, important decisions will be made next month when the policy makers sit down and discuss where we're headed, what should be cut and what should be done, in general, to eliminate wasteful spending. In other words, decisions vital to our current and future defense will be made.

In this connection, the spotlight will be on our new Secretary of Defense. Neil H. McElroy is known as a man who wants facts, not theories, from subordinates and associates. His approach probably will be much like Charlie Wilson's, viewing the job as a business rather than a political or technical problem. He is known to be digging hard for facts. He makes up his mind quickly, and only new facts can make him change a decision.

There's nothing wrong with that approach, so long as fact can be sorted from fiction. This hasn't always happened. Many people lay claim to the role, but few are missile experts. Very few. When McElroy starts digging for facts he most certainly will have to turn to some of those few who know something about missiles, those who have built and flown missiles successfully. And they are not always where you expect to find them.

To arrive at the optimum of overall missile producibility and operational effectiveness, the new defense secretary ought to call in the man who knows more about Army, Navy and Air Force missiles than anyone else . . . AF Maj. Gen. Donald N. Yates. He is Patrick AFB's energetic, eager commander. He is the only top military man who has had the opportunity—for several years—to watch all the birds all the time, who has had daily contact with the missile industry's researchers, designers and military brass—even the push-button personnel—and who has built up a truly vast scientific knowhow of our entire missile arsenal.

Gen. Yates is known as an efficient, hard-working military man—working in the interest of this country's military strength. He is a scientist as well. He is admired by his associates. He wears the Air Force blue, yet he is popular with Army, Navy and Air Force missile men alike. Call him in. Listen to him. It will pay.

all with Warheads by Honeywell

One big reason so many missiles carry warheads made by Honeywell is that the Honeywell Ordnance Division has the development and production experience and facilities necessary to handle warhead projects through their complete evolution—from feasibility studies to volume production.

Honeywell Ordnance is equipped for, and has extensive experience in aerodynamic and lethality studies and structure design. Also helping to make Honeywell Ordnance a leading supplier of warheads is the fact that all types of fuzing, safing and arming devices can be developed and produced under the same roof.

If you require development work in the areas of missile equipment, fuzing, fire control, underwater ordnance or special products, Honeywell Ordnance Division would welcome your inquiry. Phone, wire or write to Honeywell Ordnance Division, Dept. MI-9-225, Hopkins, Minnesota.

Honeywell Diversified Systems Span the Field

LIQUID LEVEL SENSING SYSTEMS keep Rockets ready for INSTANT LAUNCHING

Before the "FIRE" signal is given, a rocket or missile stands ready on the launching platform, frequently for a considerable time. Yet it must be ready to fire at any time, in spite of the evaporation of the highly volatile fuel and oxidizer liquids.

To keep fuel constantly up to capacity, Simmonds Liquid Level Sensing System senses when the fuel goes below a prescribed level. Automatically, the System then actuates a valve to add more fuel, shutting off when "full" level is reached. This process is continuous until the rocket is launched.

These Simmonds Systems have no moving parts—are shock, vibration and corrosion resistant—operate on low power consumption. They operate in any aircraft fuel, hydraulic fluid, jet engine oil and other liquids and liquified gases, meeting all MIL specs. Detailed literature on request.

GUIDED MISSILES AND ROCKETS AROUND THE GLOBE

cover picture:

Symbol of the US position in the field of liquid propellant rocket engine development is the flame and smoke of the Titan ICBM engine undergoing static test at Aerojet-General. The Titan engine, developed by Aerojet, is one of the highest impulse engines in the free world. It is our responsibility to push the Titan and Atlas ICBMs to completion to counter the threat of Russian supremacy in the arsenal of 'ultimate' weapons.

PYLE *star-line*® CONNECTORS

Assure long-lasting protection of vital connections under a wide range of extreme environmental conditions

Currently establishing itself as a performance leader in the missile systems field, Pyle-Star-Line connectors offer engineers an entirely new line of electrical connectors for universal military and industrial use.

With characteristics of construction and performance never before combined in compact, rugged, lightweight standardized connectors, they exceed NEC requirements and classes A, B, C and E of military specifications MIL C-5015C.

FEATURES

Tough, lightweight shell: Strength comparable to mild steel, yet weighs only ⅓ as much.
Anodic coating: Gives shell toughness of case-hardened steel. Takes up to 1800 volts to penetrate coating.
"Sandwich" insulation: Silicone laminate floats between two rigid discs. Silicone disc absorbs shock, lets contacts align themselves freely; rigid discs impart just the right amount of restraint. Gives all advantages of both flexible and rigid mountings.
Chamber sealing: Silicone insulation disc positively and completely prevents water, gas, moisture or dust from passing into shell.
Wide range of pin and socket configurations: Configurations from 2 to 100 poles available. Within each form size all inserts are interchangeable and reversible.

Environmental Limits of Pyle-Star-Line connectors	
Temperature	—80 F. to 225 F.
Pressure	300 PSI External, 200 PSI Internal
Chemical Resistance	Most acids, most alkalis, oil
Corrosion Resistance	Salt Spray: 300 days without failure
Dust Resistance	Exceed requirements of MIL C-5015C
Shock Resistance	50G Minimum
Vibration	Exceed 20G to Method II of Mil C-5015C
Humidity & Moisture Resistance	Exceed Class E. Spec. of Mil C-5015C
Air Leakage	Meet Class E Spec. of Mil C-5015C

Write today for complete specifications.

SPEED YOUR MISSIL

Precision Weldments in Stainless

FROM THE LEADING PRODUCE

Welding of all types on special steels and alloys can be contracted confidently at the Jet Division.

Our experience in forming, welding, stress-relieving, and heat-treat titanium, high-alloy and stainless steels for jet engine component available to you now for your missile programs. Deliveries will be prom quality will be to your required standards. Our engineering staff can a help you design and engineer weldments of all types.

Machining of weldments can also be done right in our own plant people accustomed to closest tolerances, unusual alloys and designs, aircraft-quality standards.

Let the Jet Division supplement your own overloaded missile prod tion facilities. Capital investment will be eliminated, the search for qu fied engineers and production people will be avoided. Delivery will made to suit your production schedule. Write today for a Jet Divis Sales Engineer to call.

SEND FOR BOOKLET MR-357

which describes the facilities and products of the Jet Division in detail, shows how you can use these facilities to best advantage.

For Precision Switching . . .

. . . try this Rugged and Reliable, featherweight squib-actuated switch

Designed for use in guided missile and special weapons circuits, the "OM-300 Series" Squib Switches are now available for general use wherever there is need for a compact, reliable device to open and/or close up to four electrical circuits simultaneously. The actuating squib is more sensitive than a delicate relay, yet switching action is faster and more positive than that of a massive solenoid switch.

The OM-300 Series includes all possible combinations of normally open and normally closed contacts in the four pole switch illustrated above. Switches of this series will solve many problems for designers of warhead fuzes, missile control systems, aircraft emergency systems, and missile telemetering systems.

See "ATLAS" about your Explosive-Electromechanical Problems . . . .

- Size: ½" x ½" x 2⅛" (Terminals extend ⅛") (Non-delay)
  Weight: 280 grains (.64 oz.) (Non-delay)
  Number of Poles: 4, any combination of open and closed
  Current Capacity, Closed Pole: 25 amperes continuously
  200 amperes for 100 milliseconds
- Voltage, Standoff, Open Pole: 500 volts minimum
  Energy to Actuate Switch: With carbon bridge squib—500 ergs at 50 volts (Minimum values recommended)
  With wire bridge squib—5,000 ergs at 6 volts (Minimum values recommended)
- Switch Actuation Time*: Less than 5 milliseconds
  *Actuation Times as short as 0.1 millisecond and as long as 20 seconds will be available.

Write today for additional data on this effective device.

Solid-fuel Issue is Challenge

To the Editor:

Your magazine serves extremely useful purposes. Not only does it keep the layman up to date on a common sense basis but it also provides information in well co-ordinated comprehensive form a businessman can understand.

But most important of all, the statements in your magazine must be appreciated for their authoritative value at a time when advertising writers and customers' men in brokerage offices have suddenly become experts on missiles, rockets and jets and, with the help of a few chemical terms, dispense so glibly an appalling amount of hogwash that at best represents 25 per cent half-baked knowledge, 25 per cent imagination and 50 per cent stupidity.

Your article on the solid fuel industry is excellent in every respect and I am looking forward with much pleasure to your next issue which will discuss the exotic fuels and their values, about which there is so much controversy.

New York 17, N. Y.

A New Road To Controlled Fusion?

To the Editor:

Here is an idea I thought of three years ago. I have tried to make it several times, but haven't succeeded yet.

The rocket works on the "hollow charge" principle.

I thought that this engine would increase the rocket exhaust velocity and could be throttled. The directional control is similar to the air nozzle in the Ator VTOL. Most important about this is that you might be able to have a nuclear fusion reaction in the jet of the rocket.

This could be done by having a plasma jet of tritium and deuterium focused so that the molecules collide similar to a "hollow charge" which would form tremendous heat to start the fusion reaction.

The heat problem would be solved because the fusion reaction is away from the walls of the rocket chamber.

Russell H. Jones, Jr.

Arlington, Va.

To the Editor:

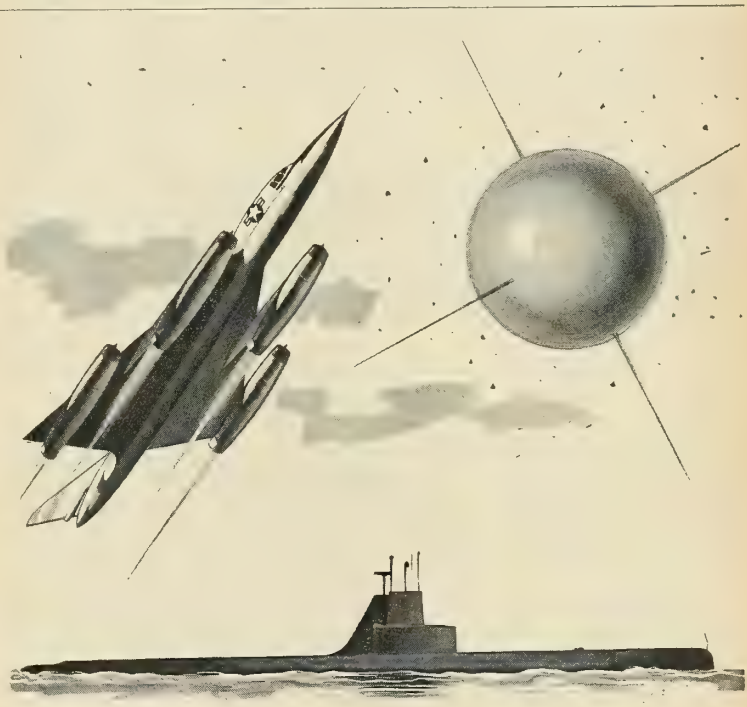
Our Society, the Asociacion Argentina Interplanetaria, is a member of the International Astronautical Federation and has nearly 500 members of which about 30% are university graduates, 35% are university students and the rest are amateurs. We are organizing a big exposition to be held in Buenos Aires, December 1957-February 1958 and expect to get some material to be exhibited from foreign countries. We will also exhibit some small rocket motors built in this country and some models of different satellites as well as designs, graphs and photographs of rockets.

We ask you to consider the possibility of sending us on a loan basis some of the material you have exhibited at the Sheraton Park exhibition hall. We are sure you have many, very interesting things to be exhibited in this great Latin American city.

Teofilo M. Tabanera, President,
Asociacion Argentina
Interplanetaria
Buenos Aires
Argentina

We feel the best sources for you to contact would be the American Rocket Society, 500 Fifth Avenue, New York, N. Y., and the State Department, Argentine Desk, Washington 25, D.C.—Ed.

SRO at m/r



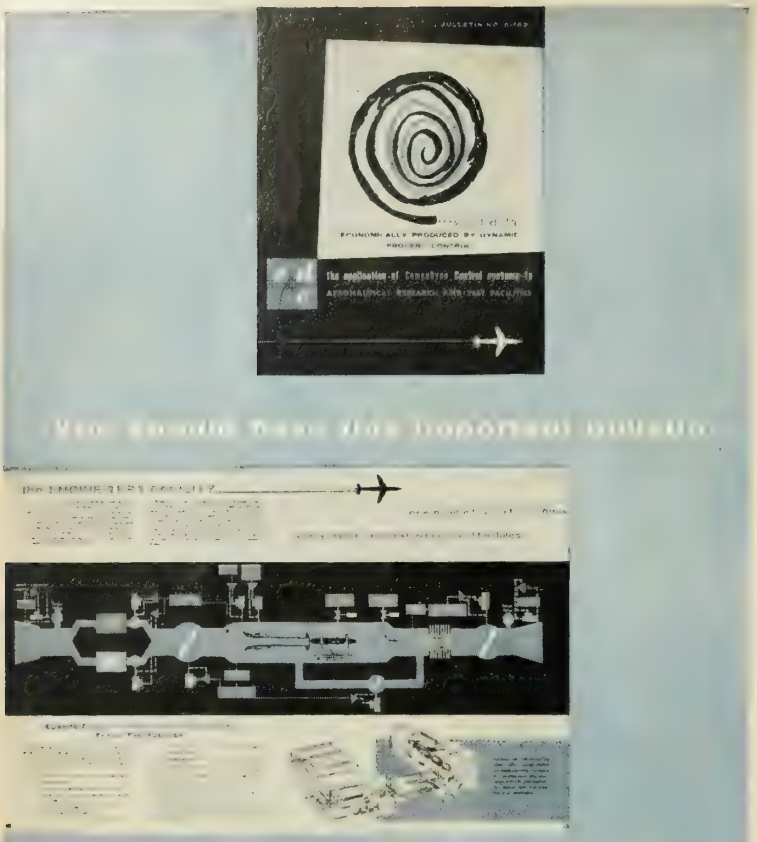
To the Editor:

I have just received a two year subscription to your magazine and would just like to say the first copy exceeded my expectations. Keep up the good work.

I would like to know if the back issues of m/r are available. My subscription started with the July, 1957 issue.

Gene A. Lewis
15718 Mandalay Rd.
Cleveland 10, Ohio

Sorry. No back issues available. All gone.—Ed.



We may have already solved your flexible ducting problem

Flexible's been solving tough ducting problems in many different fields for a great many years. And has engineered all kinds of special shapes and tubings in a wide variety of fabrics and coatings for unusual applications . . . a starter duct for jet aircraft, for example, as well as special ductings used in the missile field for ground support. So it could be that we already have the answer to your particular problem. If not, we'll put our research facilities, including our brand-new laboratory, to work immediately. If silicone ducting is called for, our special Silicone Department, working with automated machinery, is prepared to meet your specifications.

To find out how Flexible can solve your ducting problems, write us, outlining your requirements. Our engineers will be glad to put their experience to work for you. Write to Dept. 219.

Our Ed Gets New Look

To the Editor:

I am an engineering student and enjoy your excellent magazine very much.

A group of my classmates and myself were discussing MISSILES AND ROCKETS the other day. We agreed that one of the best things about it is the column, Missile Business (formerly Aerophysics), written by Seabrook Hull. He is an extremely colorful writer. However, we

Ed Hull: New Look

Ed Hull: Old Look

were curious about what he was thinking when his picture, which appears at the top of the column, was snapped. We made the following conjectures:

1) His wife had just run off with another man.
2) She came back.
3) He had just given up smoking.
4) You are not paying him what he thinks he's worth.
5) He had just been told by his doctor he has to give up drinking.
6) He had been drinking too much the night before.
7) He lost $200 on a horse.
8) Aviation Week scooped him.
9) The photographer reminded him of his father whom he hates.
10) He hates everybody.

Tom Monahan

369 Bleeker Street
New York City, New York

Thanks for those kind words on Seabrook (Ed) Hull's column. He's not quite as mean as he looks. However, Ed is such a busy man around here, we never got around to having his picture taken, so an old passport photo was used over the column. But your letter did it.—Ed.

Future Lady Missileer Wants Advice

To the Editor:

I am a junior in high school and am very interested in astronomy, missiles and rockets. I make A's in school and am taking physics, chemistry, and algebra as well as other required subjects. I think I would like to major in physics, since I am more interested in rockets and missiles and actually going into outer space than I am in just studying the stars. Could you tell me what subjects I will need, how to select a college for this, and any other information I might need?

Miss Marsha Meador

625 9th St. N.
Columbus, Miss.

There are three basic subjects that should be included in your high school curriculum—Chemistry, physics and mathematics. There are many excellent colleges throughout the country that can supply the required courses. We suggest you contact your high school counselor for individual guidance. If you are 18 years of age you can and should join

Circle No. 59 on Subscriber Service Card.

the American Rocket Society as a student member. Good luck!—Ed.

m/r Encyclopedia for National War College

To the Editor:

The National War College has selected the following item, among others, as required reading during a five-week course beginning Oct. 11, 1957:

First Annual Guided Missile Encyclopedia, MISSILES AND ROCKETS, July 1957.

Your advice is solicited with regard to securing a minimum of 160 copies for distribution to the students and faculty.

F. E. Fitzgerald
Faculty Service Consultant
The National War College
Washington 25, D. C.

Reprints are in the mail.—Ed.

A Question of Semantics

To the Editor:

There has been a rapid evolution in the aviation industry which has affected many fields. The latest to be affected appears to be semantics. Several times recently I have seen the word "sophisticated" used in aviation literature with a new meaning quite at variance with its original meaning. The latest such usage that I have noted was in your June editorial: "This Is Not the Time to Cut," where you refer to the "more *sophisticated Titan.*" Would you please enlighten me as to your definition of this ubiquitous adjective, and the authority for such a definition.

R. B. Wall
6401 Lander Lane
Dayton, Ohio

Webster's states that one of the definitions of sophisticated is "deprived of original simplicity, made artificial, or, more narrowly, highly complicated, refined, subtilized, etc." Use of the word "sophisticated" in reference to the Titan was simply to say that the Titan is considered to be more advanced and a more complex missile, which is in accordance with Webster's definition. Who started using the word "sophisticated" in aviation and missile circles isn't known, but usage has spread.—Ed.

Not That Young

To the Editor:

The fifth paragraph in the July Astrionics column is resented. Please be informed that the average age of most licensed, transmitting radio amateurs is approximately 30 years. This makes your reference to "high school kids and other amateur hams" misleading to the reader. I have enjoyed amateur radio as a hobby since 1915 and have been licensed by our federal government since 1927. My resentment comes only from unfavorable publicity the radio amateurs unjustifiably receive. Let's hear more of the many favorable things.

F. C. South W3AIR
Electronics Engr.
APL/JHU

We seriously respect the fine traditions of amateur radio operators and are sorry if Mr. South mistook our intentions. However, there are always some irresponsible persons in every field. It is because of this that the audio tones to be used are secret.—Ed.

DESIGNS RELAYS

TAILORED FOR AIRBORNE SYSTEMS

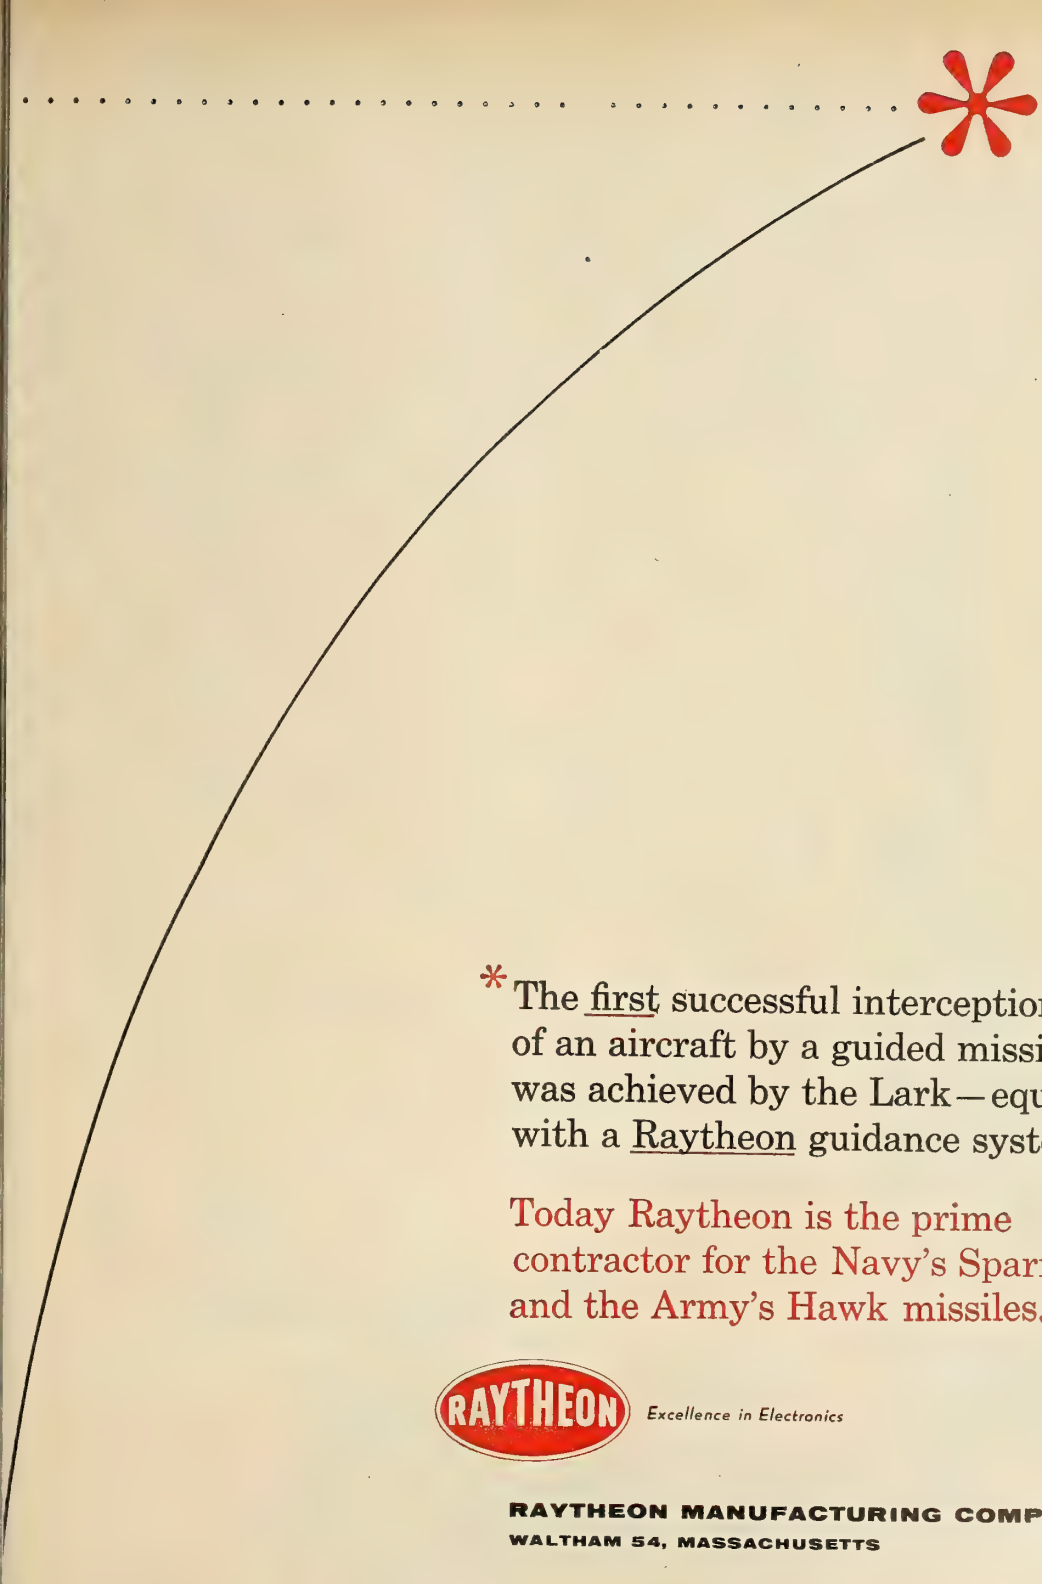
Lockheed Missile Systems announces new positions in

MISSILE FLIGHT CONTROLS — *the creative field for engineers*

Few fields equal missile systems flight controls in the need for original thinking. The ever-increasing performance of missiles presents problems that grow constantly in complexity. At Lockheed, weapon systems programs demand important advances in flight controls. Emphasis is on new ideas, new techniques.

Positions are open on the Sunnyvale, Palo Alto and Van Nuys staffs for engineers possessing strong ability and interest in: Research and development of advanced flight control systems for controlling missiles and rockets; system synthesis by application of control system feedback techniques; analysis and design of nonlinear servo systems; development of transistor and magnetic amplifier techniques in the design of advanced flight control systems; analysis and simulation of the dynamic performance of the guidance – autopilot – airframe combination; development of systems utilizing advanced types of inertial and gyroscopic instruments; analysis and design of hydraulic servo systems for controlling missiles at high Mach numbers; environmental and functional testing of prototype flight control systems.



Inquiries are invited from engineers possessing a high order of ability. Address the Research and Development Staff, Palo Alto 7, California.

SIXTY SECONDS TO CATCH A SUNFLARE

IGY leads off with an assist from CDC

Sunflares leap into space at velocities which stagger the imagination. They occur without warning and last but a few minutes. To get vital sunflare information when it's available CDC rocket crews get the two-stage research rocket off in sixty seconds! Then, from an 80 to 150-mile-high vantage point, instruments in the NIKE-DEACON or NIKE-ASP combination detect and telemeter data on the sun's radiation—important new information to expand our knowledge of radio propagation.

CDC was awarded the IGY Sunflare contract by the Naval Research Laboratory, and was responsible for modifying and assembling the two-stage rocket vehicle, and building the instrumentation-telemetering head. Here is another important activity where CDC skills are helping speed the answers to questions in high-altitude research.

COOPER DEVELOPMENT CORP.

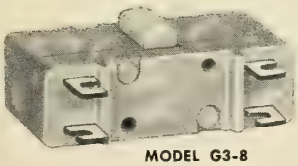
FOUR PROVEN ANSWERS TO SWITCHING PROBLEMS

Subminiature sealed switch is environment-free; mounts interchangeably with MS25085



MODEL EF-3

gle Pole, Double Throw
ve. Differential, .004 Max.
ertravel, .003 Min.
er. Force, 5 to 17 oz.
ease Force, 60 gram
c. Life Ratings:
150,000 ops. @ 125/250 V. A.C.,
2.5 AMP.
100,000 ops. @ 125/250 V. A.C.,
5.0 AMP.
50,000 ops. @ 30 V. D.C.,
(2.5 AMP., IND.; 4.0 AMP., RES.)
ib. Temp., −65° to +180° F.

Sealed in a corrosion-resistant, treated aluminum enclosure, this tiny switch is environment-free; highly vibration and shock resistant. It carries 5 amps. at 125/250 V.A.C. with an electrical life rating of 100,000 operations. Low operating force and small movement differential make it ideal for bi-metal temperature, diaphragm operated and other "feather-touch" devices, while small size permits mounting singly or ganged in restricted space. Rugged and dependable, it has positive snap action.

iny 40 amp. basic switch has high ipacity, longer life and constant ability of tolerances

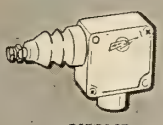
easuring only 1¾" x 43/64" 15/64", the Electro-Snap G3-8 sic Switch handles current rat-s up to 40 amps. A new thod of combining Electro-ap's double-break action with heavy-duty switching element ures electrical and mechanical of 100,000 cycles at large

MODEL G3-8

pacities; also provides constant stability of tolerances and accurate eatability. New plastic compound case gives the switch an am-nt temperature rating of —100° to +300° F. with extreme shock istance. Small size makes it ideal for motor controls and compact omation set-ups. A wide range of actuators is available.

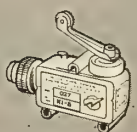
OPERATING CHARACTERISTICS

Single Pole, Double Throw
40 AMPS @ 125/250 V. A.C.
@ 30 V. D.C. Res.



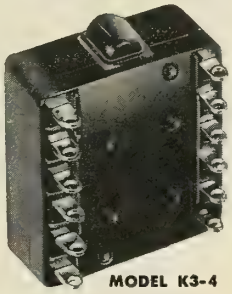
Oper. Force, 45 oz. Approx.
Overtravel, .015" Min.
Move. Differ., .055 ± .010

ELECTRO SNAP



PRECISION SWITCHES

BASIC SWITCHES



DIECAST ENCLOSED SWITCHES

HERMETICALLY SEALED LIMIT SWITCHES

CONFORM TO MIL & AN SPECIFICATIONS

Simultaneous triple-pole switch interrupts 3-phase ac. circuits; 6-circuit control in a small package

MODEL K3-4

Triple-Pole, Double Throw
15 AMP., 125/250 V. A.C.
30 V., D.C. Res.
10 AMP., 30 V., D.C., Ind.
Overtravel, .015 Min.
Move. Diff., .028 ± .007
Mech. Life, 1,000,000 ops.
Elec. Life, 500,000 ops.

This Electro-Snap triple-pole switch simultaneously reverses current flow through three windings of a 3-phase motor up to 1 H.P. and interrupts other types of multi-switching installations. Instantaneous "make" and "break" snap-action of the three poles is independent of the speed of actuation—even extremely slow moving cams can be used.

The K3-4 Series offers designers a wide variety of 3-phase circuit hookups for servo-controls, to limit movement of machine members and as a start-and-stop switch which formerly were possible only with complicated relays or a number of separate switches. A large selection of standard actuators is available.

Small basic switch is low cost; directly interchangeable with AN3234 Specs

F2 SERIES

These Electro-Snap F2 Series snap action switches are extra-compact with extremely high electrical capacity for their size. Mechanical and electrical life at 1/32" overtravel is 150,000 operations, minimum, with accurate repeatability and constant stability of tolerances. Self-aligning springs provide contact wiping action rare in a switch of this size.

Durable case of special plastic gives the switch an ambient temperature rating of −100° to +275° F. or +375° F. Available, *at low cost*, in three basic models with a wide selection of actuators.

SERIES F2 BASIC SWITCH: F2-3: Single Pole, Double Throw
F2-2: Single Pole, Normally Open; F2-1: Single Pole, Normally Closed

OPERATING CHARACTERISTICS

Electrical Rating: 10 AMP. 125/250 V. A.C. 60 cycles
30 V. D.C. inductive and resistive (6 AMP, 30 V. D.C. for Airborne Application)
Operating Force, 7 to 12 oz.
Reset Force, 4 oz. Min.
Pretravel, 3/64 Max.
Movement Differential, .011 ± .005
Overtravel, 1/32 Min.

Formsprag—pioneer in the development of sprag-type clutches—now offers a truly versatile small clutch for a wide variety of aircraft applications.

In terms of your product's performance, Formsprag FS-02 and FS-04 Clutches provide unusual compactness, utmost accuracy and torque, simple and dependable operation.

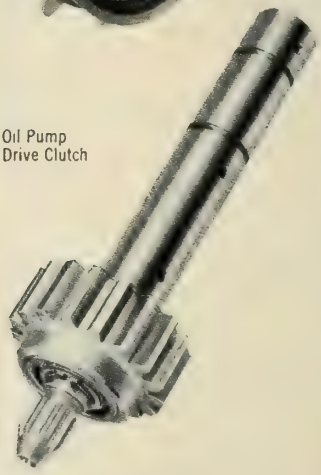
Shown is a standard model. However, inner and outer races can be machined to provide through shafts, external gears, etc. Carefully controlled aviation quality and approved inspection procedures insure outstanding precision.

HERE'S REAL COMPACTNESS

	Bore Size	O.D.	Torque	Over-running Speed
Model FS-02	¼"	1¼"	50 in. lbs.	*2400
Model FS-04	⅜" and ½"	1⅝"	200 in. lbs.	*2400

*Higher speeds possible on special applications. Consult with factory.

CHECK THESE TYPICAL AIRCRAFT CLUTCH EXAMPLES



Backstop Clutch for Ammunition Feeders

Gas Turbine Starter Clutch

Oil Pump Drive Clutch

Among other uses are backstop clutches on positioning devices for electronic tubes and automatic uncoupling for energy dissipation on radar antennae drives. The FS-02 and FS-04 series can be custom manufactured in a variety of materials including stainless steel or supplied in any specified rust inhibiting process.

MORE INFORMATION?

Should you require details on these Formsprag small clutches as well as the complete line, write today for this new 26-page catalog.

Over-Running, Indexing and Backstopping Clutches for aircraft, automotive and various industrial applications

VICKERS

miniaturized motorpumps

...for Vanguard Earth Satellite Rocket Vehicle

Numerous Vickers miniaturized hydraulic airborne components have been successfully developed for missile use without sacrifice of their inherent high efficiency and reliability. Representative of the "packaged" approach to dependable missile hydraulic power is the PFM-3906 constant displacement piston type pump shown here mounted on an electric motor. The pump has a theoretical delivery of 0.84 gpm at 7400 rpm and 1000 psi with a volumetric efficiency of 95%. The explosion proof motor has 6.0 in.-lb. torque from 6900 to 9000 rpm. The complete package weighs 8 lb. . . . 1 lb. for the hydraulic pump and 7 lb. for the electric motor. **The overall length is less than 10 inches.** For further information about Vickers miniaturized hydraulic components and complete packages, ask for Bulletin A-5216.

Taking the measure of tomorrow...

Developments from the modern research laboratories of Curtiss-Wright serve many industries today —lay the groundwork for future achievements.

An airplane powered by a Curtiss-Wright engine has flown so fast that a noon take-off in New York would land it in California at 10:20 A.M. same day—turning back the clock!

A Curtiss-Wright nuclear gauge measures the thickness of fast moving sheet materials during production—without touching them.

Curtiss-Wright produces a heat-registering paint for recording the temperatures of working parts in action.

The fields of Curtiss-Wright activity are continually broadening, and now include products for nearly every major industry . . . products of imaginative engineering in electronics, atomic power, plastics, metallurgy, ultrasonics, aviation . . . products of Curtiss-Wright research that continually take the measure of tomorrow.

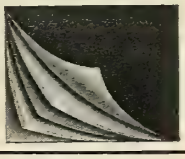
HITCO Products

Designed to Beat the Heat!

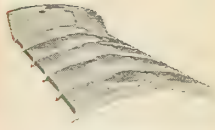
REFRASIL High Temperature Insulation in 7 physical forms:

BULK FIBER | BATT | CORDAGE | CLOTH | SLEEVING | TAPE | YARN



REFRASIL "Pre-Formed" and "Wrap-around" Insulating Blankets are preferred by the majority of aircraft and jet engine manufacturers all over the world!

WRAP-AROUND



PRE-FORMED

THERMO-COUSTI
Removable Insulating Blankets combine top Acoustical and Thermal insulating efficiency with convenient flexibility for ease of installation and removal in jet airliners, cargo and Military Aircraft.

THOMPSOglas
Formed High-Density Fiberglas is designed for Thermal and Acoustical Insulation, and is a versatile protective insulation Material for a variety of Aircraft and Missile applications.

REINFORCED PLASTICS
For Military, Industrial and Commercial Products. REFRASIL Cloth, combined with High Temp Resins, is possible liner for Missile uses. Typical High Temp Aircraft parts shown.

HITCORE Honeycomb
In Stainless Steel and a variety of other materials. Various thicknesses, core sizes and foil gages can be combined to meet your special requirements.

Power for the world's mightiest weapons:

ATLAS • THOR • JUPITER • REDSTONE

These are the names of the great new missiles of America—defense systems of unprecedented speed and striking power. To feed their monstrous thirst for power, a new kind of engine had to be created—an engine with enough propulsive thrust to drive tons of projectile in a colossal arc upward from the earth's surface to the bounds of atmosphere, and on through space itself at thousands of miles per hour.

The answer was the large, liquid propellant rocket engine. Only a few years ago ROCKETDYNE, directed by the Air Force, set out on a program to design and build these high-thrust propulsion systems—a job that meant starting from scratch, and writing the book as they went along.

Today, ROCKETDYNE can report that the power for these revolutionary new weapons is ready. Engines for the Armed Services' high priority missile programs are being built in quantity at two ROCKETDYNE plants—Canoga Park, Calif., and Neosho, Mo.

The possession of such weapons is of crucial importance to America. Free men everywhere are entitled to know that the power for our major missiles is being delivered—on schedule.

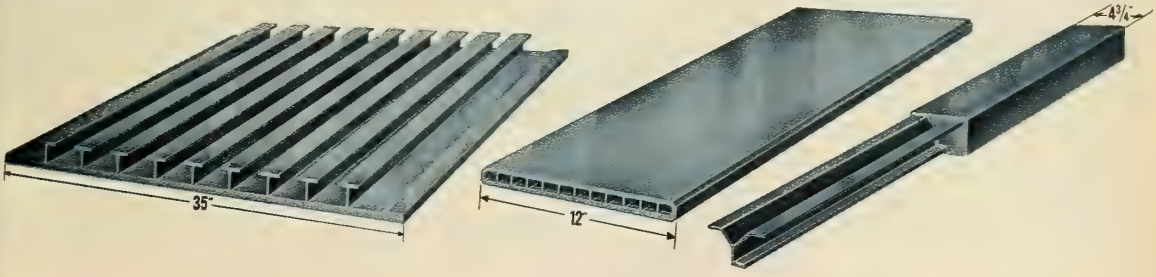
New Design Trends for

Harvey Aluminum Extrusions

To any experienced engineer or designer, aluminum extrusions are a common commodity. You don't have to tell him that extrusions offer such advantages as ease of fabrication, design flexibility, etc. He knows that. What he wants to know now are the newest advances made possible by the extrusion process.



Potential for new configurations and applications

Typical new applications for Harvey Aluminum Extrusions are illustrated below. The design possibilities for aluminum extrusions are now practically limitless. Large heavy press sections; unusually complex shapes; wide, integrally stiffened skin panels; solid, hollow, and stepped extrusions; and extra long thin sections can be obtained from Harvey in all aluminum alloys. Heat-treated shapes can be produced in lengths up to 80 feet, weighing as much as 2,500 pounds. The maximum circumscribing circle diameter practical is 25½ inches. For functional, structural, or decorative applications demanding custom design plus light weight, corrosion resistance, high strength, and a naturally attractive finish, Harvey Aluminum Extrusions are first choice. And remember, Harvey is traditional for high quality and service.

Harvey Aluminum leads in extrusions

Harvey's completely integrated facilities include a large complement of extrusion presses ranging in size from 1400 tons to 12,000 tons, stretch-straighteners up to 3,000,000 pounds capacity for lengths up to 105 feet, and the newest supporting and finishing equipment.

If you have a problem with extrusions, thoroughly qualified Harvey specialists are always ready to help you improve your product. Write to Harvey Aluminum Sales, Inc., Torrance, California, or contact the nearest sales office listed under "Aluminum" in your classified telephone directory.

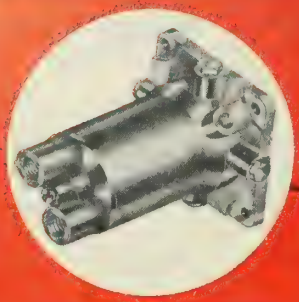
INTEGRALLY STIFFENED SKIN PANEL is produced in extra wide widths on heavy presses. Combination of skin and stiffeners in large panels minimizes machining, simplifies assembly, improves performance of aircraft, missiles, and military vehicles.

DECK COOLING PANEL for aircraft carrier is extruded on heavy presses. Light-weight, water-tight aluminum panels circulate water to offset intense heat generated against deck in jet aircraft operations.

STEPPED EXTRUSION for aircraft structural member eliminates machining and reduces assembly time. Aluminum part is lighter and stronger than outmoded built-up section formerly used.

Making the most of aluminum . . . for everyone

HARVEY ALUMINUM SALES INC., TORRANCE, CALIFORNIA



HARVEY Aluminum

Harvey is a leading independent producer of quality aluminum products in all alloys and sizes: Rod and bar, pipe, tube, hollow sections, press forgings, forging stock, impact extrusions, structurals, special shapes, extrusions, screw machine products and other aluminum products. Harvey is also producing similar items in titanium and steel.

WHY DOUGLAS ENGINEERS AND SCIENTISTS GO FURTHER . . .

At DOUGLAS, you'll work to expand the frontiers of knowledge in today's most advanced missiles program

1. Nike 2. Honest John 3. Sparrow 4. Thor IRBM 5. Secret 6. Secret 7. Secret 8. Secret

It's no secret that we're in the "missile business" to stay . . . with sixteen years behind us and an ever-expanding future ahead

There can be no mightier challenge than to be assigned to any one of the major projects now under way in the Douglas Missiles Division.

Some – like Nike and Honest John – have pioneered missile development. Others on which Douglas engineers are engaged are extending the horizons of present-day development . . . cannot be mentioned for reasons of national security.

These are the projects that require engineers who are looking far beyond tomorrow. You will use all of your talents at Douglas and have the opportunity to expand them. Your only limitations will be of your own making. Douglas is an engineer's company . . . run by engineers. Make it your working home and build an important and rewarding future in your field.

Genisco G-Accelerators play vital role in ICBM development

Threading the needle half-way round the world leaves no room for error.

Inertial guidance—self-contained guidance systems used to direct huge ICBM's to the target—depends for its accuracy upon the degree of internal instrumentation perfection. Switches, relays, delicate instruments, and hydraulic and electrical systems must operate perfectly—even while subjected to tremendous acceleration forces.

Testing components and complete asssemblies to simulated operational G-forces, as required by MIL-E-5272A, before relying upon their operation in actual flight is easily accomplished with Genisco's G-Accelerators.

Genisco's precision centrifuges are available in five standard sizes—from high-speed machines capable of high G-loadings, to large 12-foot diameter machines capable of accommodating complete electronic or electromechanical systems.

All models incorporate features necessary for critical laboratory testing, as well as the ruggedness and simplicity of operation required for production-line test programs.

Many automatic features minimize operator responsibility and chance for error. Built-in safety features and integrity of construction provide maximum protection to both personnel and machine.

Complete specifications on all machines and accessories are available. *Write, outlining your specific requirements.*

MODEL B78
Accommodates test objects up to 25 pounds; 1200 G-pounds max.

MODEL C159
Accommodates 100-pound test object on each end of boom; 2000 G-pounds max.

MODEL D184
Range of 1 to 800 G's; 1000 G-pounds max.

MODEL E185
Subjects two 300-pound assemblies to 100 G's. 30,000 G-pounds max.

MISSILE ELECTRONICS
Another AAP First

Sums up to one half of this nation's missile expenditures are invested in the *electronics* part of the business. With new, sophisticated guidance, tracking and computing systems under way, missiles will become more efficient, yet more complex. Thousands of engineers today—and many more thousands tomorrow—will put their efforts into *missile electronics* for the sake of advancing missile guidance, tracking, telemetry, data reduction, computing.

These thousands of engineers—comprising the *missile electronics* business—have not been adequately served. After an extensive survey American Aviation Publications, Inc. has decided to meet this challenge. It has decided to cover the missile electronics market and its engineers and management personnel with an up-to-date exclusive and extensive monthly presentation titled MISSILE ELECTRONICS, starting October 1957.

This "magazine"—a supplement to MISSILES & ROCKETS—will be published as a separate section within MISSILES & ROCKETS—at no additional cost to our subscribers. The two-magazine-in-one approach to the vast missile and astronautics field will enable us to serve our readers better, in that we will cover the entire field to the very utmost extent.

For this important expansion program American Aviation Publications, Inc., the world's largest aviation and astronautics publishers, will again increase its staff of top-notch editors. Needless to say, MISSILE ELECTRONICS and its readers will benefit from our worldwide staff facilities.

Your comments and suggestions as to how we can make MISSILE ELECTRONICS useful to you would be welcomed and appreciated.

Watch for the first issue, next month—October.

WAYNE W. PARRISH,
President and Publisher,
American Aviation Publications, Inc.

Shock wave around a simulated missile

SUPERALLOYS for supersonic performance

We develop them. And through modern vacuum melting produce them to the closest possible limits of chemical control and uniformity of mechanical properties for use in such critical components as aircraft turbine blades, buckets and skin material for missiles and rockets. UDIMET 500, one of our well established vacuum melted alloys, combines unsurpassed stress-rupture life with excellent ductility and fatigue strength in the 1200°F to 1800°F range. At 1200°F, for example, its tensile strength is 180,000 psi —at 1600°F, 100,000 psi. For further information concerning applications of these superalloys to your products, write to address below.

VACUUM MELTING
provides these properties

- *High temperature corrosion resistance*
- *Increased ductility*
- *Extreme cleanliness*
- *Precise chemical control*
- *Longer stress-rupture life*
- *Increased tensile strength*
- *Better fatigue resistance*
- *Greater yield strength*
- *Greater impact resistance*
- *Greater creep properties*

IS YOUR JET ENGINE RPM MEASUREMENT ACCURATE AND SAFE?

TAKCAL®

READS JET ENGINE SPEED to GUARANTEED ACCURACY of 10 RPM in 10,000 RPM (±0.1%)

The inter-relation of RPM to efficiency and thrust in jet engines is fundamental. Proper adjustments for maximum thrust, maximum engine life and maximum safety of operation can be made only upon accuracy of instrumentation. The TAKCAL tests to guarantee that accuracy.

The new B & H TAKCAL incorporates a refinement of the frequency meter principle. It operates in the low (0 to 1000 cps) range, reading the frequency of the tachometer generator on a scale calibrated in percent RPM corresponding to the engine's RPM. It reads engine speed while the engine is running with a guaranteed accuracy of ±0.1% in the range of 0 to 110% RPM. Additionally, the TAKCAL circuit can be used to trouble-shoot and isolate errors in the aircraft tachometer system, with the circuit and tachometer paralleled to obtain simultaneous reading.

The TAKCAL's component parts are identical with those used in the J-Model JETCAL Analyzer. They are here assembled as a separate unit tester and for use with all earlier models of the JETCAL Tester.

The TAKCAL operates accurately in all ambient temperatures from −40°F. to 140°F. Low in cost for an instrument of such extreme accuracy, it is adaptable to application in many other fields.

For full information write or wire...

CHECKS TACHOMETER "SYSTEM" ACCURACY. ADAPTS TO ANY FREQUENCY PROBLEM!

Explosion-proof TAKCAL for special applications. Measures 200 to 7500 RPM, direct reading, with ±0.1% accuracy.

Your project gets synergism under this roof

(as the Douglas DC-8 A-C generating system did)

Synergism gives you order instead of chaos in electrical projects involving the power side of the bus and beyond. No matter how often specs are changed.

At Jack & Heintz, we're set up for synergism—under-one-roof co-ordination and co-operation. We give you a *personal* co-ordinator . . . one of our Project Managers is assigned to your job. It's his job to accelerate your project quickly to top speed by smoothly integrating action among all product creating and producing phases. He acts fast when specs are changed . . . can quickly unravel any knotty problems created by a design change.

The result is true co-ordination of aircraft electrical projects. It must be housed *under one roof* to provide short lead time, prompt delivery and top quality and reliability.

Perhaps Jack & Heintz synergism is the reason why we produce the widest range of aircraft systems and equipment available from any single source under our one roof.

We invite your inquiry. Write to Jack & Heintz, Inc., 17637 Broadway, Cleveland 1, Ohio.

Soviet IRBMs, ICBMs Jolt U.S.

A Soviet count-downer recently pushed a button that fired a ballistic missile probably between the small missile-launching island of Kolguev in the Arctic near Novaya Zemlya, and the Northwest Pacific Sea of Okhotsk—apparently the first intercontinental ballistic weapon anywhere in the world to go the distance (over 3000 miles). Furthermore m/r learns from reliable Norwegian sources that the Reds have been launching intermediate range ballistic missiles from naval ships in arctic waters for some months and continue to do so. And while the Reds were impressing their missile prowess on the world, a group of top U.S. missile producers met in Washington and formed the National Guided Missile Industry Conference with an avowed purpose "of putting the U.S. missile effort on a more rational basis."

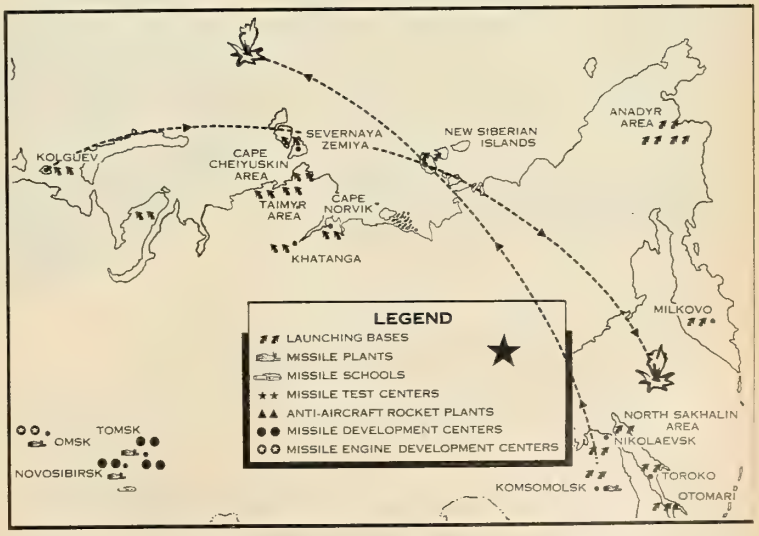
On that Monday evening when the first banner headlines of Russia's ICBM capability blared across the nation's front pages, none of the missile businessmen had forecast Soviet ascendancy in long-range missiles, but frustration and premonition were common to everyone present—"We need missiles, not politics and false economy."

On what indeed may be a fateful evening in world history, these representatives of American competitive free enterprise decided that they, if nobody else, would try to put order and efficiency into the U.S. missile effort. They are convinced missiles require a different approach from aircraft.

Those in at the founding represent some of the most successful names in missiles today—boast contracts on such important projects as *Titan, Polaris,* the *Nike* series, *Lacrosse, Talos, Falcon,* and *Hawk.*

Their organization will work, within the limits of security, to air basic guided missile problems and their solution before Congress and the American public; and to spread vital missile know-how throughout the guided missile industry. A secondary, but still important emphasis of the group will be to push producibility (low cost) as well as availability and reliability of "in-service" missiles.

In recent history, the record shows, the Russians have never made an announcement such as this on the ICBM, without there being a sound basis of fact. Announcements of Soviet A-bomb and H-bomb achievements are good examples of this. Besides, the ICBM is not a big step from the IRBM—and they have been firing these with alarming regularity.



The official TASS ICBM announcement, as quoted in a Radio Moscow news broadcast monitored by m/r describing the missile as an "over-continental ballistic missile, capable of delivering a nuclear warhead anywhere in the world." The difference between "inter-continental" and "over-continental" isn't clear, but it could imply a range over the standard U.S. ICBM figure of 5000 miles or could merely have been a way of stating that the missile was tested over the Russian land mass. A tip-off to Western intelligence sources that something big was brewing could have been the Soviet warning a short while back for all foreign shipping to stay clear of the Sea of Okhotsk, north of Vladivostok.

Furthermore, a U.S. missile engineer just returned from Russia within the last few days insists that the Reds will launch an artificial earth satellite before the end of September—probably on Sept. 17, the 100th anniversary of Tsiolkovsky's birth. Konstantin Tsiolkovsky is generaly recognized as "the father of space flight" for his proposals on reaction-powered space flight before the turn of the century.

Meanwhile, Scandinavian fishermen report having witnessed several Soviet shipboard IRBM launchings this summer. First reports of such firings over a year ago suggested that the missiles involved were Russia's 700-mile ballistic missile, the *Comet.* More recent reports indicate the missiles may now have a much greater range—could possibly be the 1800-mile T-2 (M-103).

Norwegian sources told m/r the firings take place at night under bright midnight-sun conditions when visibility and optical tracking are perfect. In addition, Russia is known to have missile-launching sites on the Kolski peninsula as well as near Novaya Zemlya. Reports have not been confirmed whether Russia has launched any big missiles from these land sites. Sea launching is considered, however, to be much more difficult. The U.S. has still not launched any ballistic weapons from shipboard.

As reported in previous issues of m/r Russia's long-range ballistic missile knowhow probably is on a par with ours. Their guidance systems might be cruder, but their production output is in high gear. Ours is not. Apparently, the Reds believe in a vast amount of crude missiles rather than a few with pin-point accuracy.

Possible flight paths of the Russian ICBM firing is depicted by dotted lines. The more probable impact point is the Sea of Okhotsk (lower right) recently closed to shipping.

Spectre: First Throttleable Production Rocket

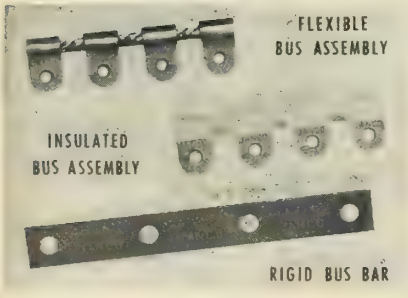
LONDON—(JAMES HAY STEVENS) In offering the *Spectre* as a production HTP/kerosene rocket, The de Havilland Engine Co. claims seven special advantages for the propellant choice: (1) automatic thermal ignition—but *not* spontaneous combustion; (2) catalytic decomposition of all HTP entering engine—i.e. avoidance of liquid injection with its explosion risk; (3) low-loss turbine drive for propellant pumps—its exhaust is used as part of oxidant; (4) controlled variable output over wide thrust range —idling less than 5% of max.; (5) ability to stop and re-start indefinitely; (6) foolproof—designed as an airplane engine with safety and long life; and (7) self-contained—propellant pumps and starting system are in the engine and it uses turbojet fuel.

Although the first practical airplane rocket—the *Walter* 509 in the WW-II Me 163 intercepter—was controllable, the *Spectre* is the first modern rocket to be throttle-operated, as distinct from multi-barrel thrust controlled.

Development by DH has continued for about ten years, starting with the *Sprite* ATO unit for the *Comet* 1. This was a 'cold' HTP unit, using solely the energy released by catalytic decomposition into oxygen and superheated steam at 1,100°F (600°C), publicly demonstrated at the 1952 SBAC Display. Next step was the *Super Sprite* 4000 lbs. x 40 sec. ATO pack for the Vickers *Valiant*, which burns the decomposition products with kerosene.

Design and prototype construction of the *Spectre* took about two years, with the first bench run in July 1953. This run was "cold"; the first "hot" run not being made until the early fall, an acceptance test being made within a month. Design rating of the *Spectre* D.Spe.1 was reached in July 1954. A water-cooled reaction chamber and nozzle were used for these early runs, but in November 1954 this was discarded and the engine was run continuously for more than one hour, using only the integral HTP cooling system.

Initial flight trials in the belly of an English Electric *Canberra* (B-57) started cold last December, with the first hot firings in January. Ground firings in the tail unit of a Saro S.R.53 were carried out in a rig at Hatfield before the airplane itself flew on May 16.



The advantages of being able to use the same fuel as a turbojet are obvious in terms of flight plan flexibility and tactical supply in the field. HTP is, at present, expensive to manufacture, but the method lends itself to mass production as economical as other oxidants. A practical design feature is that the flame temperature of HTP/kerosene not only peaks at the Stoichiometric ratio, which means cold running in the event of control valve failure, but its value of around 3600°F (2000°C) is about the limit for present materials.

The *Spectre* is now on British Security's Initial Publication List, which means only externally obvious features are revealed—dimensions but neither weights nor performance.

It is a compact, completely self-contained engine 56.5 in. long, 26.5 in. in diameter. The installation di-

Janco

QUALIFIED ELECTRO-MECHANICAL PRODUCTS FOR THE AIRCRAFT AND MISSILE INDUSTRIES

Circle No. 107 on Subscriber Service Card.

ameter over the three-point thrust mounting is 32 in. The reaction-chamber/expansion-nozzle assembly scales 44 in. long, with an overall diameter of about 13 in. and a nozzle lip diameter of some 10 in. The HTP supply pipe is nearly 2 in. in diameter, that for the fuel, over 1 in.

The cylindrical reaction-chamber-/expansion-nozzle assembly is bolted together from three sub-units—a forward end, ribbed central body and the rear casing, which is almost half the engine length. In order to achieve efficient combustion over a wide thrust range, it is necessary to use a high pressure, around 500 lb/sq. in., hence the ribbing.

The front of the *Spectre* is a gearbox casing with a large oil sump having a filler and sight level glass on the left side. The position of the gearbox suggests a turbine drive in the head of the reaction chamber, probably of impulse type and energized by a portion of the catalyzed HTP.

At the front of the gearbox is a vane-type, high rpm centrifugal pump, which delivers HTP into a pipe running along the top of the nozzle casing. Beneath the fore part of the casing, there is a smaller external pipe leading to the head of the reaction chamber.

Kerosene is delivered by a centrifugal vane pump on the left side of the gearbox to a cylindrical fuel-cooled oil cooler on the right side, after which it again traverses the engine to a valve unit on the left side of the reaction chamber.

Most of the control cranks and the various sequencing valves are on the left side of the engine. On the right, is a spherical accumulator mounted atop a pump/valve unit with a manual actuating unit. Pipes lead from the inlet side of the HTP pump to the valve, thence to the top of the sphere and from there to the reaction-chamber casing.

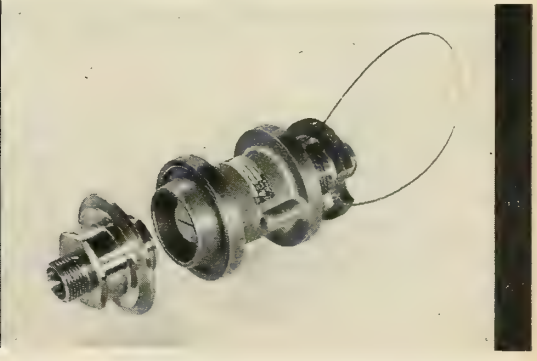
Although performance and weight data are classified, it is known that the *Spectre* was made to the same specification as the Armstrong Siddeley *Screamer*. The latter is unclassified because it was axed when the Ministry of Supply decided to abandon LOX for manned aircraft rockets. A full development story on the *Screamer* was given by S. Allen, chief engineer of Armstrong Siddeley's Rocket Division to *The Royal Aeronautical Society* on October 11, 1956.

The *Screamer* had a design sea level static thrust range from 1000 lbs to 8000 lbs; maximum thrust at 40,000 ft of 9500 lbs.

Army to Supply Navy *Polaris* Test Motor

The U.S. Navy's *Polaris* Fleet Ballistic Missile program is still a joint Army-Navy operation—in part at least. Thiokol Chemical Corp. holds a contract from Army Ordnance to supply engines for *Polaris* test vehicles. This is in cooperation with Lockheed Aircraft Co., prime *Polaris* systems contractor. These are full-scale missiles. The firing schedule has all the earmarks of a crash program, with actual flight tests to begin this fall. This means Navy's already well ahead of previously announced targets for getting an operational FBM.

Navy, apparently, is taking full advantage of the knowhow that has been accumulated by ABMA at Huntsville, Ala. Though Aerojet-General Corp. is officially designated as the *Polaris* rocket motor contractor, it is not beyond the realm of possibility that Navy is running a competitive development program as between Thiokol and Aerojet to see who comes up with the best solution to *Polaris* propulsion problems. If so, look for a later determination between the two, as to just which one gets the final production contract.



Little information is available as to the exact nature of the *Polaris* missile, except that it is to be a 1500-nautical-mile ballistic missile, capable of being fired from either surface ship or a submerged submarine. It will be powered by a solid-propellant motor and be about eight feet in diameter and 40-to-45 feet long. Every effort will be made to keep its length down, including such devices as the use of multiple exhaust nozzles, say, four instead of one. This configuration offers other advantages as well, such as: imparting spin by canting the nozzles; enabling any number of nozzles to be fired as desired; and a possible gain in efficiency as more complete burning is achieved in the plenum chamber.

Stromberg-Carlson Opens New Facility

Stromberg-Carlson, a division of General Dynamics Corp., has opened its new administration building and recently purchased electronics center at Rochester, N. Y. The facilities provide an additional million sq. ft. to the company's expanding telecommunication and electronics business.

ON MARK

quick-disconnect couplings for missiles, aircraft and ground support equipment

Typical of the precision-built quick-disconnect couplings designed and produced by ON MARK is Part No. 5-8016-12, as illustrated. These efficient couplings range in size from ¼" to 2" inside diameter, with sizes up to 10" or larger available on special order.

Fluids handled are compressed air and gases, ordinary and "exotic" fuels, liquefied gases, peroxide, ammonia, hydraulic fluids, ethylene oxide, turbine exhaust gases and low pressure cooling air. Operating temperatures range from –340° F. to 1000° F., operating pressures from –14.7 psi to 3000 psi.

ON MARK quick-disconnect couplings utilize various operating methods – disconnecting remotely by compressed air, electrical solenoids, lanyard, pullaway, breakaway and combinations of these methods. They can also be connected or quick-disconnected with one hand in a single simple, push-to-connect motion under full line pressure of 3000 psi.

Five reasons why Cherry "700" rivets* give you superior fastening

1. The "700" rivet design produces sheet clamping action that is superior to any other blind rivet. This same clamping action guarantees consistent uniform head seating.

2. Cherry "700" rivets provide a positive hole fill, even in oversized holes. Simplifies hole preparation problems in the shop and reduces hole drilling costs.

3. Wide grip range. One rivet can be used for several material thicknesses, thus reducing stock and lowering costs.

4. When installed, the wire-drawn portion of the stem, as shown, indicates that (1) a blind head has been formed, (2) the sheets have been clamped together, and (3) the rivet has expanded to fill hole.

5. High uniform stem retention is maintained within a greater hole tolerance range because the stem always adjusts to fill the hole.

Let us demonstrate the superior features of the Cherry "700" rivet in your shop on your trouble spots. Call or write Townsend Company, Cherry Rivet Division, P. O. Box 2157-Z, Santa Ana, Cal.

X-17 Nose Cone Has Mirror Finish

A ballistic missile test nose cone, with one of the smoothest surfaces created by man, has super buffing and polishing prior to flight into the ionosphere on the Air Force's X-17 re-entry rocket. The AF said the X-17 has brought many ballistic missile test nose cones past the extreme re-entry temperatures.

Underground Factory In the Works?

HUNTSVILLE, Ala.—A series of obscure real estate transactions is now nearing completion here. Execution of the final deed to some remote mountain property on the big bend of the Tennessee River is expected to clear the way for start of a much-discussed but little publicized project believed to involve American Machine & Foundry Co., Redstone Arsenal and the Army Ballistic Missile Agency. (See m/r, May '57).

For almost two years now, a group of citizens who work to bring new industries into this area has been quietly buying up, in their own names or through proxies, various parcels of land scattered about nearby Green Mountain. This is a big ridge, about 1500 feet high and five miles long, a part of the Blue Ridge-Smoky range that cuts across Northeast Alabama to Birmingham. Green Mountain lies across U.S. Highways 231-431 from Redstone Arsenal and stops at the very edge of the Tennessee River.

The men who have been buying up the tracts of land on Green Mountain are all members of the Huntsville Industrial Expansion Committee. The city being what it is—a rapidly-expanding missile and rocket center—it has been impossible to conduct such operations in secrecy.

There have been persistent reports that AMF is planning some kind of

THE ELIN DK-102 PRECISION POWER OSCILLATOR!

® Reg. U.S. Pat. Off. Pat. Pending.

For top precision performance in the oscillator field it's ēlin oscillators that can speed your results, save dollars! Ideal for pre-flight missile system checkouts, precision 400 cycle gyro testing, special power sources, time correlations, etc.—*wherever* you need "tuning fork" Frequency Stability, Absolute Voltage values, extremely low Output Impedance, Ultra-low Distortion and High Power Capacity!

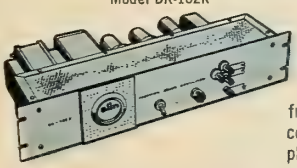
The ēlin Precision Power Oscillator gives you all this through an exclusive High-Q LC tuned circuit and special voltage-sensitive bridge combined in a circuit employing a large amount of negative feedback. Standard model—2 watts power output (6 watt model, DK-106) and at audio frequencies between 250 to 15,000 cps. Special models available in higher power capacities and at other frequencies or to customer specifications. Write for literature TODAY!

SPECIFICATIONS:

FREQUENCY
250 CPS. to 15,000 CPS.

POWER
2 Watts (DK-102, DK-102R).
6 Watts (DK-106, DK-106R).

VOLTAGE
10, 30 & 100 volts RMS.
All with floating, center tapped output.



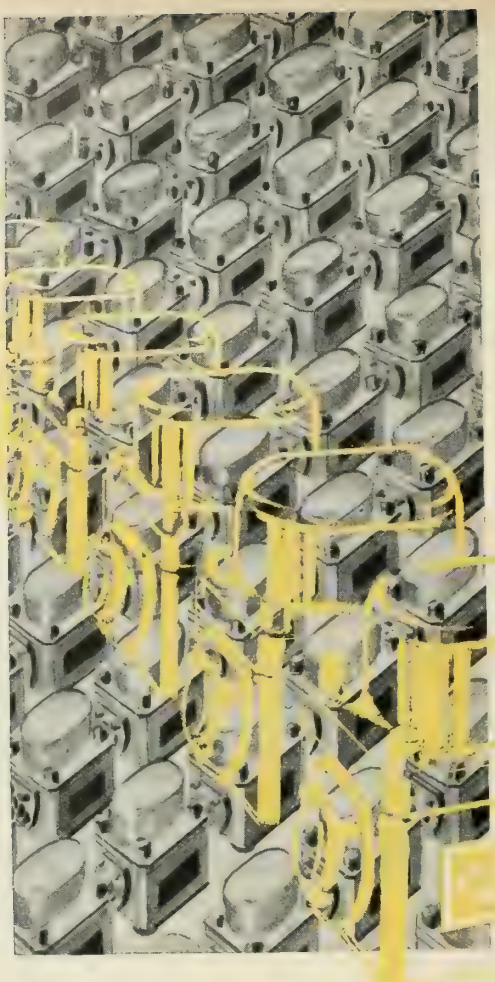
DISTORTION
0.1% maximum harmonic content
0.05% maximum AC hum
0.01% maximum noise

FREQUENCY STABILITY
±0.5% maximum, under usual ambient conditions.
±0.02% maximum, per ±10 volts variation in line voltage.
±0.05% maximum, zero to full load.

AMPLITUDE STABILITY
±0.1% maximum, under usual ambient conditions.
±0.02% maximum, per ±10 volts variation in line voltage.
±0.2% maximum, zero to full load.

PRICE: $295.00 (Subject to change without notice.)

Model DK-102R



ELIN LEADS A "DOUBLE LIFE" of quick-change versatility providing fast modification from a DK-102 (cabinet model) to a DK-102R for rack mounting! All models are smartly styled, compact (5¾"H x 9"D x 16⅞"W) and built to give reliable, trouble-free service. 115V AC plug-in power is made to either lugs or AN adapter at rear of chassis!

underground factory in the mountain, perhaps for the manufacture of missiles, rockets and components. AMF officials are here periodically for closed sessions with officers at Redstone and ABMA and the Industrial Expansion Committee. None will say anything publicly about the Green Mountain reports; neither has anyone denied them.

The latest acquisition of some 35-40 tracts is said to clear the big promontory for whatever purposes are in mind, although there is another report that one more tract remains to be purchased—one that is legally complicated because it involves property that passed to the Alabama State Board of Education under a will. This transaction, however, is said to be virtually completed.

Earlier this year the same group negotiated the purchase of some 200 acres on the river at the very end of Green Mountain. This is now to become the site of new state docks, presumably to serve the new installation and also to help cart away the vast quantities of limestone that must be excavated if the factory is to be built.

Informed sources say that some explanation of all the mysterious moves in and around the mountain may come within six months.

Missile Submarine Launched at Mare Island

The Navy's first submarine built primarily as a guided-missile sub was launched in June at the Mare Island Naval Shipyard. Capable of handling the *Regulus* missiles, the *Grayback* (SSG 574) is scheduled to join the fleet in July, 1958.

The two submarines now operating with the fleet as guided-missile subs, *Barbero* and *Tunny*, were converted to missile-carrying subs after first operating as conventional submarines. Two others being constructed are the *Growler*, a conventional powered submarine and the *Halibut*, the Navy's first guided-missile, nuclear powered submarine, and the first ever designed from the keel up as a guided-missile carrier.

Funds for three additional nuclear-powered guided-missile submarines have been requested in the fiscal 1958 budget.

Gilfillan Receives *Corporal* Contract

Gilfillan Brothers, Inc. has received a $695,000 contract for *Corporal* ground guidance improvement, it has been announced by the Department of Commerce.

Big B Rocket May be Major Breakthrough

Primarily Army's *Big-B* and *Big-B Junior* programs involve major developments in solid rocket propulsion. Whether the knowhow is applied to a 2000-mile missile, a 750-mile missile or a 12,000-mile missile is, for the moment, academic.

The most important point is that by the application of wholly new techniques to conventional solid propellants, considerable gains in mass ratio as well as thrust, and possibly specific impulse, are expected. Details of just what these techniques are, is a closely guarded secret. It is known, however, that from a manufacturing point of view, there are no really thorny problems in the way of rapid progress. Static tests of the first motors are expected to take place within a few weeks.

Once the new state of the art has been proved out, solid propellants for large-missile applications will hold a much more competitive position with the liquid rocket engines that are now doing the big jobs. Doing this work is Thiokol Chemical Corp. at Huntsville, Ala. This solid propellant breakthrough is believed to involve several simultaneous approaches to different problems. One is believed to be concerned with a new appreciation of the old principle of several smaller nozzles replacing one and firing out of a high-pressure plenum chamber—such as Thiokol is supplying on its *Polaris* test vehicle motors.

Electronics Spending Predicted at $3.5 Billion

Military spending for electronics may reach the $3.5 billion level by the end of the current fiscal year, according to an estimate made by the Radio-Electronics - Television Manufacturers Association. This will top by $700 million fiscal 1956's $2.8 billion expenditures.

The estimate is based on the premise that fourth quarter government spending often approaches 60% of the total of the three preceding quarters. Through the first three quarters this fiscal year military spent $2,492 million.

New Building Spurs Payroll at Redstone

HUNTSVILLE, Ala.—July's new construction contracts awarded at Redstone Arsenal, Army Ballistic Missile Agency and Ordnance Guided Missile School bring the value of the building program now under way at this huge Army rocket and missile center to more than $24 million.

Temporary employment of some 1500 persons on the new projects has boosted the work force at the three installations to almost 16,000, the highest total in its history. More than 14,500 people are working permanently at the three agencies.

Largest of the new projects involves five buildings for the Missile School—three classroom and laboratory structures and two shop buildings costing nearly $4 million. Blount Bros. Construction Co. of Montgomery, Ala., contracted to complete this project by June 1958 in time for the slated expansion of the Missile School from its present 1750 students to 3500 in 1958.

Other new structures at ABMA include: a missile surface treatment facility, an acceptance test and qualification building and an engineering mission support building.

In varying stages of construction now are: three static testing service buildings, a $4,280,000 four-building complex for structures and mechanics use, a guided missile test shop, a missile assembly and inspection hangar, an addition to a structural fabrication laboratory and 270 family housing units.

400 Days to Reach Mars Army Scientist Says

HUNTSVILLE, Ala.—The first projected time table for travel to and from Mars has been set by Dr. Gilford G. Quarles, scientific consultant at Army Ballistic Missile Agency here.

An ionic propulsion ship, using an earth satellite platform, would require 400 days to reach Mars, he says while the return trip would take 300 days.

"Although interstellar travel must await the development of more efficient propulsion systems, such as the photonic system, interplanetary travel is definitely within the scope of present technological feasibility," he declared.

"Daffynitions" Amuse Redstone

In the wake of Dave Morrah's *Saturday Evening Post* comic series on the mixture of German and English terms invented by his fictitious Herr Schnibbel, it was inevitable that the close co-operation between former German scientists and U.S. missile men at Redstone Arsenal should result in their own glossary of terms. Here are some "daffynitions" concocted by bi-lingual jokesters:

guided missile—das skientifiker geshutenwerke firenkrakker
rocket engine—firesphitter mit schmoken-und-schnorten
nuclear warhead—das eargeschplitten loundenboomer
celestial guidance—das skrewbalische schtargazen peepenglasser mit komputenrattacen schteerenwerke
engineering department—das aufguefen grupe
project engineer—das schwettenouder
structural test engineers—das pullenapardten grupe
security detail—das schnoopen bunche
hydrogen device—das eargeschplitten laudenboomer mit ein grosse hollengraund und alles kaput.

Amoco Solid Rocket Plant Nears Completion

Amoco Chemical Corp.'s new factory at Seymour, Ind., for the manufacture of solid-propellant starters for jet engines, is expected to be finished this November. Standard Oil Co. of Indiana, a pioneer in ammonia-based propellants, did the original research work leading to development of the solid propellant starters. The $3.5-million Air Force production contract for 300,000 of the units is handled by Standard's subsidiary, Amoco Chemical Corp.

Meanwhile, Standard's Research Laboratories at Whiting, Ind., and Seymour are continuing work under Air Force contracts on solid-propellant grain sizes for various purposes.

Martin Announces Missile Cooling System

Baltimore, Md.—At a press conference last week the Martin Co. disclosed the development of an advanced missile cooling system. System was designed to combat heating from aerodynamic friction in high-speed flight and electronic components.

Main feature of the system is the use of water as a cooling medium instead of the frequently used ammonia systems. Martin announced that the system has undergone one year of ground testing with an excellent performance record. Advantages over present cooling systems is its compact size, low cost and ease of manufacture.

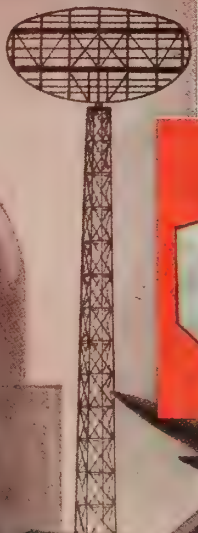
ERCO GROWS



bringing new strength to the armed forces private industry and the free world

ERCO, long a leading contributor to the field of air power, as a major supplier of flight simulators, tactics trainers*, weapons support systems, countermeasures and extensive engineering and manufacturing facilities, gains tremendous strength in combining with NUCLEAR PRODUCTS. As a result of this combination the ERCO facility at Riverdale (divisional headquarters) is now supplemented by a plant in Buffalo and a complete nuclear physicist-engineering staff in Washington, D. C.

Today not only can you rely on ERCO to design and build the same high quality equipments as it has in the past, but you can expect an amazing range of new products which will be made possible by the joint skills of Nuclear Products and ERCO's engineering and production teams. . . . . Flight Simulators . . . . . Nuclear Research and Power Reactors . . . . . Weapons Support Systems and Equipment . . . . . Nuclear Products for Defense and Peace . . . . . Electronic Countermeasures . . . . . Specialized Machinery for Automated Production . . . . . This is a new dimension in creative engineering and manufacturing available to you through Nuclear Products-Erco.

Jupiter Guidance Hits 99.98% Accuracy

A *Jupiter-C* test vehicle, consisting of a *Redstone* first stage, cluster of *Recruits* second stage and another cluster of *Recruits* third stage, recently flew 1200 miles and landed within 400 yards of its target. That works out to about a 0.02 per cent miss error—or 99.98 per cent accuracy.

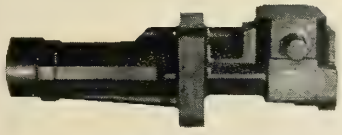
This was the Army rocket flight that also achieved a 400-mile altitude and a reentry velocity of 12,000 miles per hour. Just prior to the warhead hitting the Atlantic, a capsule was ejected containing a letter addressed to Maj. Gen. John B. Medaris, Commanding, Army Ballistic Missile Agency. This was recovered.

The reentry velocity was in the same ballpark as that which will be faced by ICBM and IRBM warheads. It is significant that the nose cone made the reentry flight down to the ocean's surface intact. It is also significant that this nose cone is reported to have been a nonmetallic structure.

No statement, official or otherwise, has been made as to the guidance system used in this *Jupiter-C* flight. However, it seems virtually certain that it was the radio-inertial system developed under ABMA direction jointly by Jet Propulsion Laboratory and Motorola's Western Electronics Division.

More *Vanguard* Details Given to Congress

Incrementally, version by version, the story on the Project *Vanguard* satellite creeps out. With the recent request to Congress for an additional $34.2 million "to complete the project", some additional facts were put on the public record by Office of Naval Research Chief, Rear Admiral Rawson Bennett and others of his staff, including Dr. John P. Hagen, Project *Vanguard* Director, Naval Research Laboratory. Amplification and additional details, however, were placed off the record.



In what for a Capitol Hill committee hearing was a mild session on the record, Adm. Bennett placed the blame for rocketing *Vanguard* costs on the General Electric first-stage engine, the Aerojet-General second-stage and "some structural troubles with the vehicle itself."

Near the end of the brief hearing, Rep. George H. Mahon (D., Texas), Chairman of the House Appropriations Subcommittee on Defense Department Appropriations, asked Adm. Bennett about reports that the Army had the capability for launching an artificial earth satellite, and at considerably less cost than *Vanguard*. Adm. Bennett replied:

"I would like to answer that on the record. The Navy Department was selected by the Department of Defense on the basis of the considered recommendation of the Stewart committee, a committee of nationally known experts, to do the job. This assignment was made with complete knowledge of the work which was going on in all agencies. Therefore, we are proceeding with it as best we can. (Discussion off the record.) We were asked to do a job to further science and we are trying to do that. On that basis, we have no comment on the rumors."

Clarification on the troubles with the first-stage engine only serves to muddy the waters. Again, quoting Adm. Bennett from the hearings: "In the case of the first-stage G.E. engine,

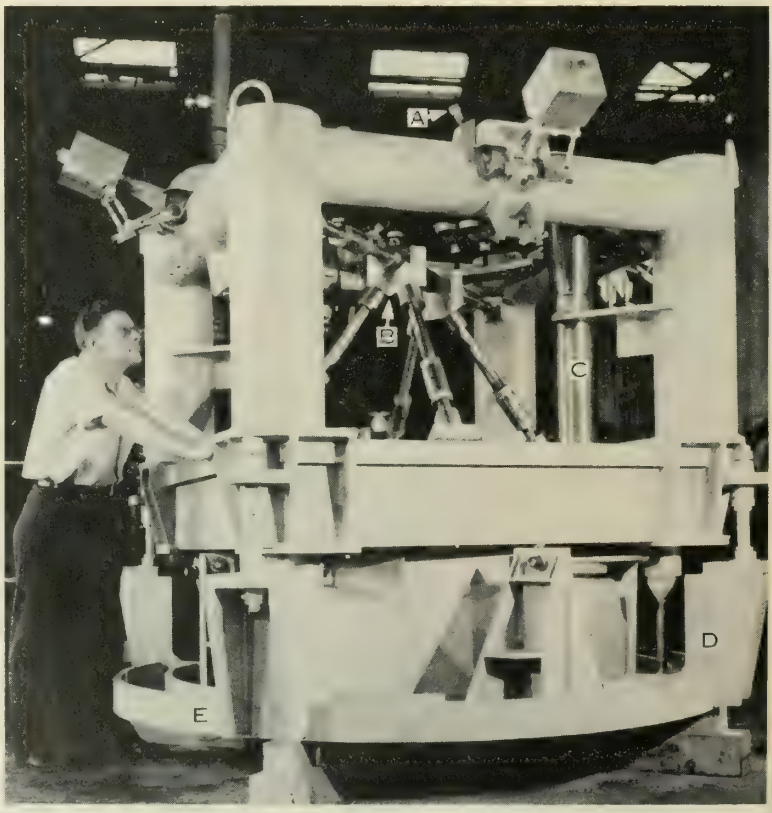
it seemed to burn out. A lot of work was required to find out why, and then to correct it. Briefly, the real answer was that quality control: the nozzles, the injectors, and other items were not accurately enough made so that unusual heats, that is, local heat spots in the engine, would be prevented. Once that was realized and corrected, the first-stage engine was on the beam."

This conflicts with other stories of what happened to General Electric's engine. GE engineers suggest that the trouble with the first three engines delivered to the prime contractor and rejected was as follows: In subjecting the delivered engines to hydrostatic test prior to static test firing, water of insufficient purity was used, and afterwards the engines were not properly cleaned. A period of time elapsed prior to test firing. During that period, rust spots developed which in turn resulted in hot spots and burnout.



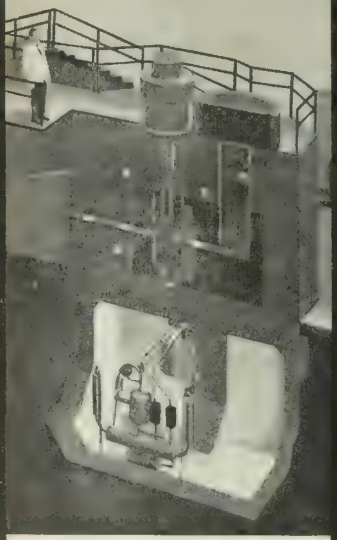
Second-stage engine experienced a similar sort of trouble which was eventually corrected. He pinned down structural problems with the vehicle as a "computational suspicion that vibration, etc., would set in within the vehicle frame."

As a result of these and other problems, as well as an initial inability to estimate costs properly in advance on such an unfamiliar project, "to date, The Martin Co. estimates its committed costs to be $47,581,000. This figure has built up from an original estimate of $28,649,000, made in March 1956."

The total estimated cost of the satellite program now stands at $110 million. These are directly chargeable or traceable costs. Of this, the Navy is responsible for supplying all but $13,874,000. The latter amount is being supplied by the Defense Department and National Science Foundation.

Adm. Bennett does not anticipate any further major costly problems, but doesn't rule them out either.

Vanguard Launching Platform Displayed



VANGUARD launching and static test platform, manufactured by Loewy-Hydropress, as it awaited shipment to Patrick AFB, where it has been installed for some weeks. (A) Pull-away pickup points on which the rocket rests, (B) the tripod which supports the engine, (C) pipe to carry exhaust to flame deflector, (D) one of four load cells to weigh rocket, fuel, measure thrust and similar functions, and (E) weighing ring for the entire unit.

Rocket Trends

by Erik Bergaust

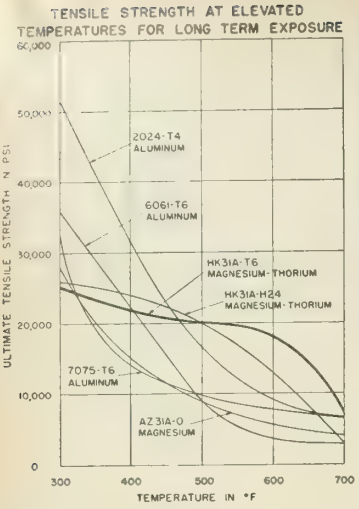
WASHINGTON IS WHISPERING ABOUT A POSSIBLE MERGER of the *Atlas* and *Titan* programs. This comes sooner than expected and may be nothing but a rumor. It is conceivable that *Titan* will be taken off the super-priority list. In line with current streamlining and cutbacks, Air Force might want to save some money on expensive overtime work etc.

LOOK TO TWO LARGE CHEMICAL FIRMS to enter the missile picture. One is about to receive a dollar-per-year information contract. (Chose the Air Force because of its open-minded attitude about proprietary rights.) The other company has already spent considerable money in R&D on new solid propellants for industrial uses.

THROTTLEABLE, INFINITE TIME, ON-OFF SOLID PROPELLANT SYSTEM is under test. The system does not employ an auxiliary liquid system for throttling. Standard motor configuration is used for on-off operation. The system is being written into several drawing-board missiles.

JUPITER PROGRAM IS STILL HANGING FIRE. Ford's missile subsidiary is trying to get this IRBM to keep its Chicago (near Midway Airport) plant going. An alternate Ford site may be the Navy reserve engine plant at Romulus, Mich. Meanwhile, Chrysler has lined up 180 potential large vendors for *Jupiter* and is considering a solid-propellant back-up version (to meet increasing solid demands from *Redstone* and to compete with Aerojet's solid *Polaris*).

PHILLIPS PETROLEUM IS REPORTED AS NOT BEING TOO INTERESTED in such high energy oxidants as ammonium perchlorate. Because Phillips' process uses extrusion equipment, grain scale-up is probably now at its peak. From publicly shown pictures, it looks like Phillips is not likely to exceed ¼-million lb/sec for single grains.



AMERICAN POTASH & CHEMICAL HAS TAKEN ANOTHER STEP nearer getting into the rocket picture. National Northern of West Hanover, Mass. has been acquired by AmPot and will work on squibs, igniters, gas generators, and solid rocket propellants. AmPot is a leading producer of potassium perchlorate and the new lithium oxidants—the nitrate and perchlorate. AmPot also is the nation's only large-scale producer of ammonium perchlorate—which forms the basis for virtually all of our present high-energy composites.

SOVIET MISSILE SPIES IN THE US must have an easy time. All one has to do is drive down US Highway 70 toward Alamogordo, N.M. The *Dart* anti-tank test range is clearly labeled and visible from the road. In addition, all targets are numbered (you can easily determine the distances with your speedometer and take a jim-dandy picture with your camera), so that width of traverse and range can be estimated.

DEATH OF *LOKI* HAS LEFT AMERICA OPEN TO ATTACK by low-flying, enemy cruise missiles. Even effectiveness of *Hawk* (which will not be operational for several years), is questionable against modern low-altitude jet planes or even sonic cruise missiles. A barrage flak rocket is still needed in the defense picture and *Hawk* is designed for a fleet of large bombers and not one single hostile airplane.

REACTION MOTORS INC. HAS DEVELOPED A PACKAGE liquid propellant rocket system. The Navy has expressed considerable interest in the system as a competitor for solid propellant systems. Major feature of the system is its capability of providing a constant total impulse.

DIMETHYL ETHER COMPLEX OF BORON TRIFLUORIDE has been found useful in a process of separating the isotopes of boron. The dimethyl ether complex of boron trifluoride is converted to potassium fluoborate by introducing the complex into an aqueous ethanol solution containing potassium fluoride, expelling ether liberated from the complex and recovering the potassium fluoborate formed.

Creep Resistance at 300°-700° F.

In this temperature range, use the thorium-containing alloys of magnesium. They are the only satisfactory metals which combine creep resistance with good strength and light weight.

For designers of high speed jet planes, rockets, and guided missiles, this solves a problem. Formerly it was thought necessary to use heavy materials. They are less satisfactory than these magnesium alloys.

Formerly available in the form of castings only, thorium-containing magnesium alloys now come in rolled sheet. B&P's mill produces this sheet.

B&P engineers will help you redesign in magnesium. B&P offers the magnesium industry's most complete facilities for fabrication and assembly. Your inquiry will bring a descriptive booklet.

Space Medicine

By Hubertus Strughold, MD., PhD.

In a paper given at a symposium on astronautics in Cranfield, England, in July, Dr. Hans G. Clamann from the School of Aviation Medicine at Randolph Air Force Base, Texas, dealt with the importance of metabolic water production in the human body, for a closed cabin system in space flight. In such a system, green algae could be used to convert carbon dioxide and water into oxygen, and into food for the occupants. But over a long period of time, through biological oxidation which reconverts oxygen and food into carbon dioxide and water, an excess of water is continuously produced in the human body and would eventually accumulate in the cabin. This throws cold water on the plans of those space enthusiasts who hope to go into interstellar space, which takes much more than the time necessary to complete this chemical transformation. Thus, in space travel of long duration, the astronaut is faced with a new type of barrier—a "water barrier"—within the closed ecological system of the cabin, which can only be overcome by returning to the paleological stage of an amphibian like the crocodile or by finding some method of dealing with this excess water.

•

Two books have been published in the Soviet Union by Astronomy Professor G. Tikhov under the titles ASTROBIOLOGY and ASTROBOTANY. They deal essentially with the botanical aspect of life on Mars. The greater part of Tikhov's discussion is devoted to the optical properties (reflective and absorptive) of the blue-green areas on Mars, as compared with those of terrestrial plants in the subarctic regions. Studies of this kind are closely related to the work of the Institute of Aerophotography in Leningrad.

•

The books report that a special institute, known as the Department of Astrobotany, has been founded in Alma-Ata, Russia. It also includes a description of an astrobotanical garden, in which hardy cold-resistant plants from the Antarctic which may be possible on Mars, are cultivated.

•

At the School of Aviation Medicine, Maj. Gen. Otis O. Benson, Jr. has expanded the Department of Space Medicine considerably, so that it can cope with all conceivable problems in missile and space operations.

•

Several space medical papers will be presented at the annual Congress of the International Astronautical Federation in Barcelona, Spain, Oct. 7-12. Maj. David G. Simons of Holloman Air Force Base, N. M., will discuss Medical Problems Involved in Sealed Gondolas; Dr. Siegfried J. Gerathewohl will give a paper on producing the Weightless State in Jet Aircraft; and Dr. Ingeborg Schmidt of the University of Indiana at Bloomington, will present research on the Visibility of Artificial Satellites.

•

The writer will attend the Barcelona meeting, representing the Space Medicine Branch of the Aero Medical Association by request of the president, Alfred M. Mayo of the Douglas Aircraft Co., who cannot be present because of other commitments.

EDISON'S SIZE 11 GEARHEAD MOTOR

1000 TO 1 GEAR RATIO UNIT USED IN BOEING'S BOMARC

Typical of the specialized servo motor work done by the Edison Instrument Division is a size 11 gearhead motor with 1000 to 1 gear ratio. This unit is currently being supplied to Boeing for use in its newest missile project, the Bomarc.

This gearhead motor offers minimum size and weight for systems designers, and extremely fast delivery schedules on units of this type make its use mandatory wherever applicable.

Edison's capabilities in servo motors, servo instrumentation, and associated precision equipments and systems are the result of years of cumulative engineering experience and the best in modern machine shop and quality control facilities. When critical requirements are necessary for servo motors or allied components, or if you'd like to know more about Edison's Systems work, write for *The Systems of the Instrument Division.*

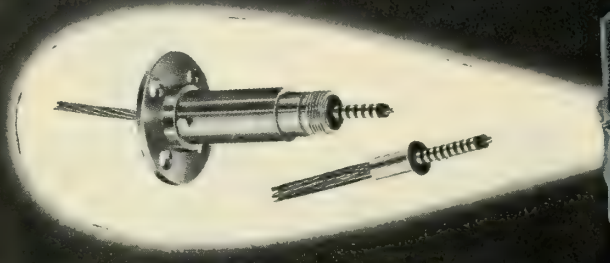
WHY ECLIPSE-PIONEER SELECTED



Poly-Scientific
SLIP RING ASSEMBLIES

Eclipse-Pioneer Division of Bendix Aviation, demands the ultimate in quality and performance for its 14104 Vertical Gyro.

This precise instrument requires extreme miniaturization of the slip ring assemblies for minimum torque on its gimbal axes . . .

Generated noise levels have to be held to extreme minimum . . .

Poly-Scientific assemblies offer these advantages and more

Extremely close dimensions, tolerances, and concentricity—strength and rigidity—coin gold ring for wear resistance, tarnish resistance and dielectric strength . . .

And what's more, all these requirements are met at reasonable cost.

If you have need for high quality slip ring and brush assemblies, commutators or other similar miniaturized components . . . whether it be for design, prototype or production requirements . . . Write for the full story, now. Or, if your need is urgent, call Prescott 2-8042, today. Our teletype number is Blacksburg 42.

INTERNATIONAL NEWS

By Anthony Vandyk

Trainer Role for Britain's *Fireflash* Resented

The Fairey Aviation Co. is very bitter at the British administration's relegation of the RAF's first production missile, the *Fireflash,* to a training role. The Weapon Division's Executive Director, C. H. Chichester Smith, says the *Fireflash* WS met all its specification requirements—exceeding several—and points out that it is fully tested, tropicalized, winterized and in production *now*, whereas delivery of the early operational models of the D.H. *Firestreak* will only start eighteen months from now.

Although tailored to the now abandoned Supermarine *Swift,* the *Fireflash* has been successfully adapted as a two-missile installation on the Hawker *Hunter* 6. The beam-riding guidance of the *Fireflash* is an all-weather all-altitude system, in contrast to the infrared homer, which can be foiled by thick cloud.

It seems likely, however, that RAF Air Staff policy has changed on the basis of two factors in beam-riding guidance; (a) human error possibility during period between launch and hit, during which pilot must keep narrow pencil beam aligned on target and (b) the fact that pilot must continue to head toward the possible explosion of a nuclear bomb load.

It is also apparent that the external boost system used to accelerate the *Fireflash* dart must have considerably higher drag than an internal rocket motor.

Description

The *Fireflash* WS consists of a fighter plane fitted with a radar beam, a gunsight, a simple "permission-to-fire" computer, with aircraft-to-missile services and a battery of missiles.

The missile itself is a cruciform unpowered dart which is boosted to maximum speed by two solid-propellant rockets externally mounted on its forward end. During the boost phase the unguided missile is spun by offset venturi nozzles to minimize dispersion due to asymmetric thrust.

At burnout, an explosive separation device throws off the spent rocket cases laterally, leaving the dart to coast supersonically toward the target. The rudders, indexed at 45° to the wings, unlock at separation and the missile is roll stabilized by aileron-type (differential) rudder action to a datum established at launch.

As soon as roll error is reduced to specified limits, guidance commands are switched to the control blocks. The missile's position relative to the axis of the radar beam, measurable in polar co-ordinates, is interpreted as Cartesian linear errors resolved in the two control planes, pitch and yaw.

The pneumatic actuator, served by electro-pneumatic relay valves, applies rudder deflection which reduces linear errors and returns the missile toward the beam-axis. During this gathering phase, clamping diodes limit maximum lateral acceleration. The missile then rides along the beam axis, following any beam motion which may occur.

Thus accuracy of *Fireflash* is dependent upon the accuracy with which the beam is laid on the target. In daylight the fighter pilot simply tracks the target by keeping the image at the center of his gunsight graticule. The radar beam axis is accurately harmonized relative to the gunsight axis, so that the only significant guidance error introduced is that due to the aim-wander of the pilot airplane combination in tracking the target.

Development trials were carried out by Fairey on suitably modified

Cut-away view of FIREFLASH booster rocket and attachment fittings.

Meteor 7 and *Meteor* NF 11. Successful beam-riding has also been demonstrated from a two-weapon installation in a *Hunter*. A third installation, in a RAF squadron of *Swift* F 7 fighters, is currently operating as a missile training unit. Installations in other planes are practicable and simple.

Construction

The *Fireflash* breaks down conveniently for ground handling into the rear cylindrical portion of the dart, which contains all the control, guidance and power supply equipment, mounting wings and rudders and an explosive assembly comprising the warhead and its fuse, the two boosters and their separation gear. This assembly is simply attached to the main body of the dart, after it has been fully pre-flight tested on a Fairey O.A.T.S. (Operational Airfield Test Set).

Structurally, the rear body of the dart is a magnesium-zirconium alloy extruded and forged tube, into which slides a two-rail chassis carrying the internal equipment. The wings and rudders are aluminum alloy precision forgings machined only over their attachment bosses.

The boosts are attached to each other by a U-shaped separation unit and fittings on the motors mate with holes in the warhead case. The fuse is attached to the warhead, and a spacer device forward of the fuse tip pre-tensions the assembly to make it adequately rigid.

The separation gear comprises a twin piston-cylinder breech block containing 0.06 lb of cordite. The pistons, attached to one motor, are held by shear pins in the cylinders attached to the other motor. A single igniter in the base of the unit flashes to the two separate charges in the two cylinders.

A pressure switch, which arms on build-up of pressure in the boost rocket case and fires when the pressure subsequently falls to 250 lbs/sq in., is located in the nose of each rocket. These are series-connected, so that when both boosts are all-burnt, a firing pulse is passed to the igniter.

The pressure in the cylinders builds up until the shear pins fail and the boosts then separate relative to each other and to the dart. The boosts are fitted with stabilizing fins to prevent toppling after separation, which could cause deceleration fast enough to endanger the firing airplane.

Control and guidance components mounted on the chassis, from front to rear, list as follows:

- Forged light-alloy 3,000 lb/sq in. air bottle, internal reducing valve, electro-pneumatic stopcock.
- Lateral accelerometers measuring in the two control planes.
- Air-blown gyro assembly: roll displacement gyro, two rate gyros for the two control planes. These are con-

THE VITAL DIFFERENCE

Flight-proved high temperature FLUOROFLEX®-T hose assemblies

...for 3,000 psi Hydraulic Service

FLUOROFLEX®-T:
Aviation's most advanced hose

The Original fluorocarbon hose

Patented tube compound

Greater flex life

Superior impulse life

Leakproof, blowoff-proof fittings

Two years of flight experience now stand back of this high temperature 3000 psi hydraulic hose . . . the best proof of reliability.

This hose achievement reaffirms that the Fluoroflex-T patented tube does make a *vital* difference . . . affording corrosion-proof plumbing of highest integrity. The lines have solved the fatigue problems met in many high temperature high pressure applications. Their Resistoflex-designed fittings locked tight to hose give complete assurance against blowoff under severest conditions.

These assemblies are the first to pass the Wright Field high pressure, high temperature hose tests.

VITAL FACTS ABOUT FLUOROFLEX-T

All Fluoroflex-T hose starts with Teflon powder — which is only a *raw material.* It's a known fact that compounding ingredients and the fabricating techniques used with Teflon can vary properties in the end product *substantially.* Therefore, the fabricator's integrity and experience are the user's best assurance of performance and reliability.

Many years of research and testing went into the development of the unique and patented Fluoroflex-T tube. The 3000 psi hose assemblies emphasize anew the conservative policy of Resistoflex in presenting a product. *Long term* testing and *field service* were essential phases in the development. Send for data.

® *Fluoroflex is a Resistoflex trademark. Teflon is a DuPont trademark.*

tinuously blown while the missile is attached to the airplane, but coast during missile flight—the rate gyros have speed monitors.

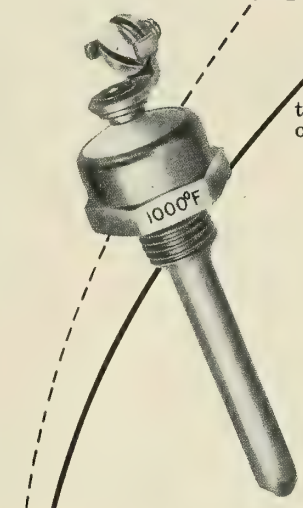
- "Receiver": electronic component blocks predominantly interpreting received guidance signals, plus control system electronic components.
- Electric power supply assembly.
- Servo motor comprising actuator, four pairs of piston-cylinder units and four electro-pneumatic relay valves.

Russians Design Burner Devices for Rock Boring

Russia claims to be pioneering in the development of non-military uses for "rocket" engines.

Scientists at Moscow's Bauman Institute—an aviation research center—have designed burner devices for boring granite and other hard rock with a gaseous stream obtained by combustion of kerosene. Sections of rock at which the incandescent streams of gas are directed are heated rapidly and unevenly. This causes the rock to break up instantly into scales that are blown out of the bore hole.

According to the Russians, this method allows holes of various diameters to be bored in the hardest rock "many times faster" than by mechanical methods. By reducing the exhaust velocity of the gas, it is possible to make a pocket for explosives.



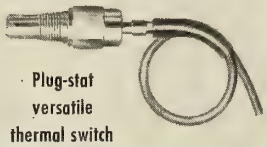
Soviet reports say that this form of heat boring is cheaper than any other process and is being introduced at quarries and pits. Portable "rocket borers" are planned for mineral prospectors.

Red Meteorite Probe In Progress for IGY

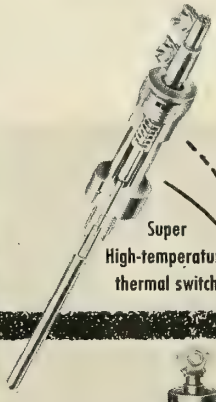
The Soviets report that their IGY study of meteorites is being concentrated in four observatories: at Kharkov in the Ukraine, Kazan on the Volga, Tomsk in Siberia, and Stalinabad in Tadjikistan (Central Asia). Accounts of this work are being made public by Professor V. V. Fedynsky.

At Stalinabad, Pulat Babajanov, a young Tajik scientist, is in charge of meteorite work. He guides the "meteorite patrol," as the Russians call their meteorite-photographing camera. As the result of the camera's continuous performance, the Stalinabad observatory now owns hundreds of photographs of meteorites in flight. With the aid of these photos, Babajanov and his associates are calculating the meteorites' trajectories and speed.

New CPI thermal switch is *Light and Lively*



This new lightweight (weighs less than one ounce) thermal switch features an operating differential of plus or minus only one degree with extremely fast response.



With an effective calibration temperature rating from −20°F +1000°F, it will even operate accurately when subjected to momentary undershoots to −80°F and overshoots to as high as 2000°F.

Wherever fast-acting, sensitive, thermally responsive regulation is required for control of dangerously high or low temperatures, this "LIGHT and LIVELY" switch will do the job accurately, dependably.

Ask about these CPI switches, too.

Plug-stat versatile thermal switch

Super High-temperature thermal switch

Hermetically sealed fire detector type

Thermal switch for temperatures to 1200°F

How KENNAMETAL* helps to send it on its way

Seal rings in pumps handling red fuming nitric acid for rockets face a most severe test against corrosion, especially since they may be in contact with the acid for years before being required to operate.

In one particular assembly, rings were exposed to temperatures of 300° under 45 psi face pressures while rotating 17,500 rpm. The previously used material lasted approximately 120 minutes. Then rings made of Kennametal grade K501 were installed and one of the world's leading designers and manufacturers of aircraft components and systems, reports average life of the Kennametal rings as "over 120 minutes to indefinite."

They state that "the Kennametal rings sealing results have been far superior with no indication of seal face wear" and that "the Kennametal ring has indications of less bending and distortion when installed between two mounting faces making assembly simpler and reducing assembly time."

This is only one of the dozens of instances in the development of missiles and rockets where getting a design off the board and into the air depended on finding materials with unusual properties. Kennametal has been usually successful in filling these needs, providing not only corrosion resistance, but heat and abrasion resistance, also.

Why not get full information . . . and, if you wish, recommendations as to which Kennametal type would best fit your particular needs. Just write KENNAMETAL INC., Dept. R, Latrobe, Pa., and ask for our new 12-page Kentanium booklet.

World Astronautics

By Frederick C. Durant III

The orbits planned for the Russian IGY satellite vehicles have been reported to be "at a small angle to the meridian." Reliable information just received indicates that the orbit will be about 60°. The U.S. orbit selected will be about 35°. This choice by the Russians will permit viewing of their satellites by a much wider portion of the earth than those of the U.S. Areas which will be able to view the U.S.S.R. satellites include Great Britain and all of Europe from Madrid to Oslo, the northern half of the U.S. and most of the U.S.S.R.

•

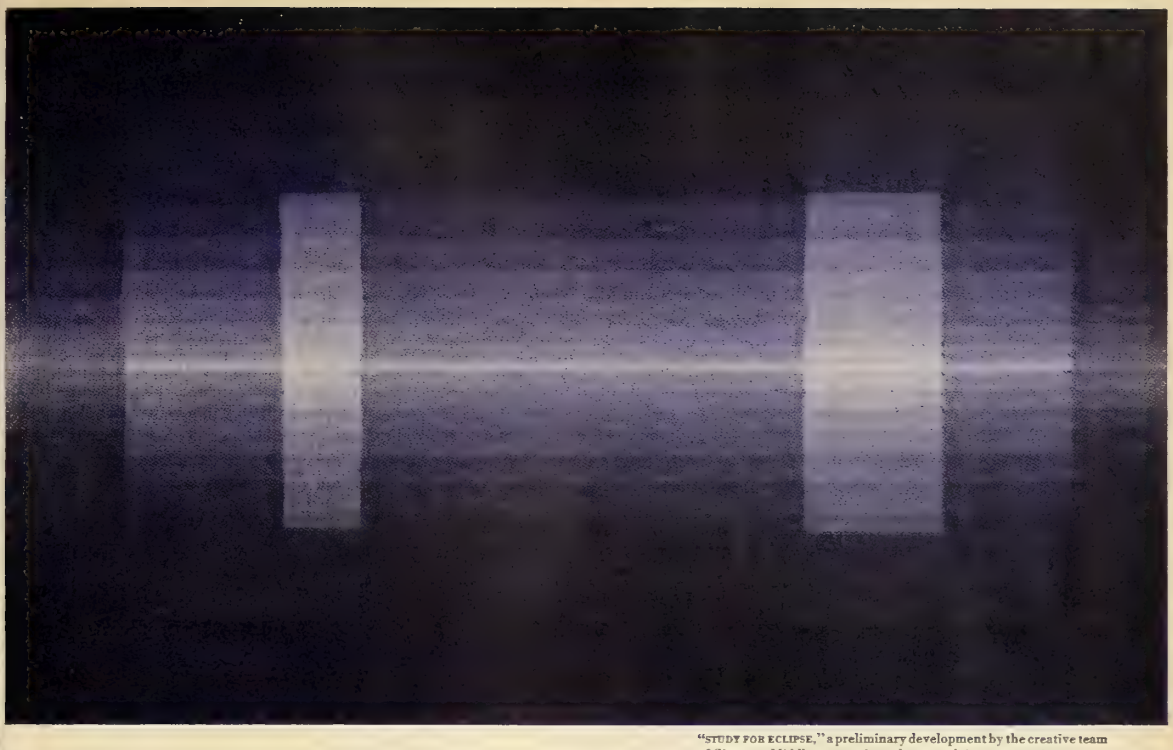
Astronautical personalities from all over: Photon rocket pioneer Dr. Eugen Sänger, Director of the Forschungsinstitut für Physik der Strahlantriebe e.V. Stuttgart, has been hospitalized for a cardiac condition. First President of the International Astronautical Federation and a rocket scientist for more than 20 years, Dr. Sänger's many friends wish him a speedy recovery.

Len Carter, Secretary of The British Interplanetary Society, and editor of the excellent JOURNAL OF THE BRITISH INTERPLANETARY SOCIETY for more than 10 years, is stepping down from his post because of press of other Society duties. Carter rates a real expression of thanks.

Two recent birthdays are noted in Germany. Dipl. Ing. Leo Zanssen, former Major General at Peenemünde, celebrated his 60th. WELTRAUMFAHRT editor and ex-BMW rocket engineer and author, Dipl. Ing. Heinz Gartmann celebrated his 40th. British physicist and top science fiction writer Arthur C. Clarke writes from Colombo, Ceylon, where he has been aqua-lunging, that he'll attend the IAF Congress at Barcelona in October. His latest work, THE MAKING OF A MOON (Harpers), has just been released. Former German rocket expert Dipl. Ing. Rolf Engel, Technical Director of C.E.R.V.A., Heliopolis, for the past five years, has left Egypt with combustion specialist Dr. U. T. Bödewadt. Engel is now in Rome acting as a consultant to the Italian Ministry of Defense.

•

From Japan comes word that Mitsubishi Shipbuilding Co. is concentrating on liquid propellant research for rockets. Japan Oil Co., Asahi Trans. Co. and Japan Carlit Co. are working on solid propellants.



•

The West German government has purchased 1000 jeep-launched SS-10 anti-tank missiles from France. The similar anti-tank rocket development of Bölkow Luftfahrtenwicklungen, Stuttgart, is in the latter stages of development.

Rocket motor tests of increasing size at the Deutschen Arbeitsgemeinschaft für Raketentechnik, Bremen, had to be shut down recently because of "noise and danger" at the local airfield. This is an old story to amateur rocketeers. New test facilities have been completed near Oldenburg, about 30 miles west. Tests on the oil-spray rocket (m/r April, p. 88) will be conducted on the nearby Zwischenahner Meer during the DAFRA meeting this month.

•

Artemis Press, London, has recently published the fascinating SPACE ENCYCLOPEDIA. Eight well known authorities (including NRL's Homer Newell and space medicine man Dr. Hubertus Strughold) have written an excellent reference work. Details of guided missiles and upper atmosphere research are uniquely combined with a survey of all branches of astronomy.

"STUDY FOR ECLIPSE," a preliminary development by the creative team of Simpson-Middleman, artists whose work is a penetrating expression of the forces and phenomena of the natural sciences. This painting is one of the steps—ground structure—in which the ultimate action will take place. Courtesy of John Heller Gallery, Inc.

Find the design of your future—at Boeing

Engineers and scientists at Boeing are today busy determining the shape and nature of aircraft and missiles for the years to come.

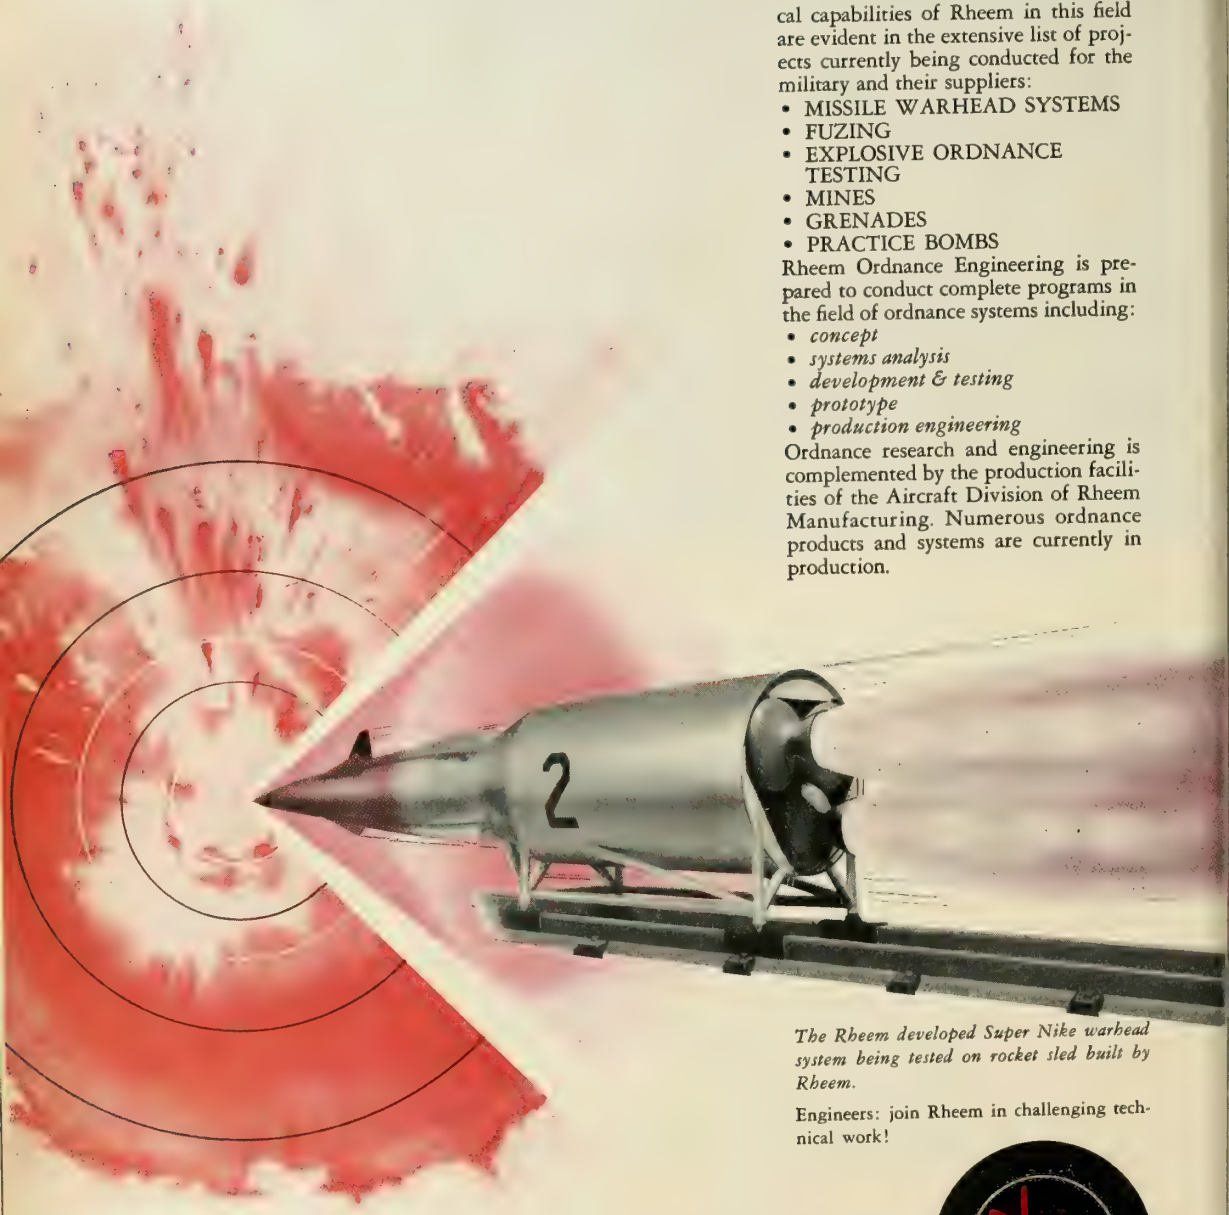
You could, among their advanced projects, find the design of *your* future . . . in such fields as inertial or electronic guidance, chemical fuel propulsion, supersonic guided missile weapons systems, or in any of the myriad aspects of extreme supersonic flight.

There are challenging, and superior, openings at Boeing now—not only in design and research, but in production and service as well.

Drop a note now, to John C. Sanders, Engineering Personnel Administrator, Boeing Airplane Company, Department R-67, Seattle 24, Washington.

BOEING

ORDNANCE



The design, development and testing of advanced ordnance products and systems is one of the principal activities of the Research and Development group at Rheem Aircraft Division. The technical capabilities of Rheem in this field are evident in the extensive list of projects currently being conducted for the military and their suppliers:

- MISSILE WARHEAD SYSTEMS
- FUZING
- EXPLOSIVE ORDNANCE TESTING
- MINES
- GRENADES
- PRACTICE BOMBS

Rheem Ordnance Engineering is prepared to conduct complete programs in the field of ordnance systems including:

- *concept*
- *systems analysis*
- *development & testing*
- *prototype*
- *production engineering*

Ordnance research and engineering is complemented by the production facilities of the Aircraft Division of Rheem Manufacturing. Numerous ordnance products and systems are currently in production.

The Rheem developed Super Nike warhead system being tested on rocket sled built by Rheem.

Engineers: join Rheem in challenging technical work!

Behind the Curtain

By Dr. Albert Parry

"Our bombs and rockets are no worse than yours," said Nikita Khrushchev to a group of American tourists in the Kremlin on July 24.

Note that Khrushchev did not claim their rockets are superior to ours. Could be that he didn't then want to alarm the U.S. into a redoubled effort to catch up with the Soviet Union. Only a week before, an alarming report was published in the U.S. press that the Soviets had been firing intermediate-range ballistic missiles for at least 18 months at a rate of more than five a month—this against our successful testing of just one non-operational IRBM, the Army's *Jupiter*.

Soviet policy is highly opportunist, however, attempting to soothe or panic the world according to the political dictates of the moment. Thus, the recent ICBM announcement comes at a time when Russia wants no interference from the West in its efforts to grab off Syria; just three weeks prior to the opening of United Nations debate on Hungary; and near the end of deadlocked London disarmament talks.

Red policy is also contradictory sometimes, as witness the peace-loving protestations of Russian scientists Anatoly Blagonravov and Yu. Khlebtsevich on "soon-to-be-fired" Red moon rockets.

Contrary to certain American fears, they said in TRUD, the Soviets do not plan to appropriate the moon. Says Khlebtsevich, Chairman of Moscow's Scientific-Technical Committee on Radio-Tele-Guidance in Astronautics: "The aim of the Soviet scientists is not at all to establish military bases on the moon so as to threaten the U.S. from there. Our efforts in astronautics are to penetrate the secrets of cosmic space the soonest; to comprehend the measureless universe the deepest."

According to Professor A. A. Blagonravov, head of the Technical Sciences Division of the Soviet Academy of Sciences, the construction of war bases on the moon "is an absurdity to any sober-thinking military expert in any country." The Soviets feel, declares Blagonravov, that "the unfurling of any national flag on the moon should not at all be the basic goal" of the world's astronauts.

To prove the peacefulness of the Red rocket-to-the-moon plans, both Moscow scientists suggest that Americans join with the Soviets in all research and rocket-building, not only with our brains but also with our dollars.

The economy-minded among us are tempted by Khlebtsevich when he insists that the Russian blueprints of such rockets and their flights "will be far less expensive than American projects" of similar enterprise. Let's start right away, Blagonravov urges. "We would be glad to inaugurate a steady, firm contact with the scientists of the U.S. working in astronautics; also with American interplanetary rocket societies."

•

The official Soviet telegraphic agency TASS gives prominence to unofficial information from Bonn that West Germany and Great Britain have prepared a "secret" plan of collaboration in developing and producing certain "modern types of weapons," including "guided missiles and rockets with a distant radius of action."

The plan, says TASS, was slated for early discussion in London by "military experts of both nations." The report adds that the West German government has a similar cooperative plan with France.

With this report as Moscow's excuse, we may now expect more of a Red admission that missile-and-rocket work is being carried on by the Soviets in East Germany.

A
Vought
Vignette
NO. 5 IN A SERIES

Why the Missile Engineer Never Missed Mail Call

Vought's Regulus II missile took shape just a short walk from the desks of its developers. Engineers handled the new hardware and monitored tests in person — literally flying the big missile on the ground at Dallas. It was a convenient arrangement while it lasted.

Then a big USAF Globemaster landed and taxied to Vought's Experimental Hangar. The missile was winched aboard and airlifted to a desert site for flight tests. By nightfall there was a 1,000-mile rift between Regulus II and home base.

Joe Boston was ready to step into this gap. As Project Assistant for Field Liaison, he'd already equipped Vought's desert crew for extensive flight tests. Now he'd make sure that test data and hardware flowed uninterrupted from the desert to Vought. High-speed feedback of facts on one flight could influence the success of the next.

Mail from the desert poured in to Joe at Vought. From project men at the flight test site came parts for immediate rework and return. From the flight test crew's mobile ground station came rolls of telemetered brush records. From the recoverable Regulus itself, came packets of oscillograph data. And from Field Service — for repair or replacement — an occasional wrench or relay.

Joe served as clearing house and consultant. Flight data was reduced and released to design and support groups. It revealed not only missile performance, but the temperatures and pressures of a strange new environment. When data pointed toward design changes, Joe's time and cost estimates helped specialists reach decisions.

Thanks to Vought's fast overland relay of hardware and data, the records of one flight were decoded and digested in time to improve the next hop. Dividends in performance and reliability were obvious after six flights had been logged by Regulus II.

All six had been flown by one vehicle.

Chance Vought uses comprehensive testing and data analysis to assist the engineer through unexplored problem areas. Test facilities strengthen every phase of the development cycle, and procedures are aimed at feeding data quickly into the engineering process. For details on select openings, write to: C. A. Besio, Supervisor, Engineering Personnel, Dept. MR-5.

CHANCE VOUGHT AIRCRAFT
INCORPORATED DALLAS, TEXAS

Washington Spotlight

By Henry T. Simmons

Appointment of the Holaday-Schriever-Medaris committee to determine the final configuration of the Air Force's 1,500-mile IRBM was calculated to raise the decision from an interservice to a "national" level, according to one Pentagon insider. He believes it may be the first of a series of high-level actions aimed at eliminating sources of interservice wrangling over missile assignments. Though no decision has been made at this writing, the odds apparently favor selection of the *Thor* engine-airframe combination, with the decision as to guidance and control left open until a later date.

•

North American is scheduled to fire four more XSM-64 *Navaho* test vehicles during the remainder of the research program authorized by the Air Force. Landing gear will be removed and no attempt will be made to recover the birds. Ironically, NAA's launching attempt last month worked perfectly, following four successive failures. The test vehicle reached design speed and altitude and covered a distance of 350 miles. The success came almost exactly one month after cancellation of the project.

•

The Air Force's new "multiple-source" development policy will have a greater impact on the missile industry than any other group of defense contractors. As outlined by Assistant Air Force Secretary Richard Horner (R&D), the policy calls for joint development undertakings by two or more companies in order to restrict outlays for new facilities. This means a company proposing a technically superior solution cannot expect USAF facilities support as in the past, but will have to enter into licensing arrangements with another firm which does have the necessary facilities. "We recognize our deficiencies in officiating at such a marriage," Horner said, but declared there is "increasing evidence" that the aeronautical industry will accept the new arrangements.

•

Most disconcerting exhibit on display at the D.C. Armory during last month's Air Force Association convention here dealt with aviation medicine. It showed a cutaway section of a rocket nose cone with chambers containing models of two disconsolate monkeys. The simians appeared to be making unearthly cries, but it was later discovered that the noise came from a squeaking bearing in an exhibit in the next booth.

•

Rocket propulsion appears to be losing its monopoly in the USAF's arsenal of airborne missile systems. The new WS-131B air-to-surface missile, awarded to North American, will use turbojet propulsion. Fairchild J83, General Electric J85 and other new engines have been suggested. USAF weapon system planners believe that turbojet propulsion offers more room for growth in certain missiles than rocket power.

•

A high-level civilian committee may be created in the Pentagon in the near future to coordinate the release of missile technical data to NATO countries interested in building U.S. missiles under license. The committee would presumably control the types of missiles cleared for use by the nation's foreign allies. The Navy's *Sidewinder* has been mentioned as one possibility for the NATO countries, and there have been suggestions that Britain will build the Air Force's intermediate-range ballistic missile when it is fully developed.

OptiTherm® Radiometers
first in Infrared
Radiation studies

A Barnes OptiTherm Radiometer is essential for precise, quantitative infrared radiation studies of military targets or backgrounds. These instruments are so rugged and stable that they have been successfully used in airborne as well as field studies. Barnes equipment was the overwhelming choice of a majority of the participating groups in the pioneering ARDC Infrared Measuring Program.

Barnes 4" and 8" Radiometers feature thermistor bolometers, uniformly sensitive from ultraviolet to far infrared; or cooled and uncooled photoconductors for specific wavelengths; an internal black body reference standard, for accurate absolute measurements; single or dual channel operation. Temperature differentials as small as .001°C can be detected—with a speed of response as fast as 16 milliseconds.

Advances in radiation and remote temperature measurement owe much to developments that originated with the Infrared Division at Barnes Engineering. They are equipped and staffed to develop your infrared systems.

If you are thinking of using infrared, write for complete information on the integrated line of Barnes OptiTherm infrared radiometers, sources, detectors and components.

BARNES ENGINEERING COMPANY
Stamford, Connecticut

Are you on the mailing list for TECHNIQUES? This publication, devoted to developments in infrared detection, will be sent on request.

Now! Constant Damping Without Warm-up

Linear Accelerometer
Type LA-500
Shown actual size.

LINEAR ACCELEROMETERS
for Aircraft and Missiles

DESCRIPTIVE DATA

- RANGE: Up to ±60 G full scale.
- DAMPING RATIO: 0.6 ±0.2 (from −65°F. to +175°F.).
- LINEARITY: 1% of full scale.
- PICKOFF: Can be provided with 2 potentiometer pickoffs (center taps optional).
- SIZE: 1 7/16" dia., 3 1/4" long.
- WEIGHT: 1 lb.

HONEYWELL LINEAR ACCELEROMETERS of the Type LA-500 Series are true linear, non-pendulous type instruments, inherently insensitive to cross-coupling accelerations. These instruments are available in a variation of ranges from ±1 G to ±60 G and can be provided with two potentiometer pickoffs. Essentially constant damping is maintained automatically throughout the entire operating range of −65°F. to +175°F. No warm-up time is required.

The combination of constant damping, high performance, small size and ruggedness makes HONEYWELL LINEAR ACCELEROMETERS of the Type 500 Series ideally suited for aircraft and missile applications where the most severe environmental conditions are encountered. Write for Bulletin LA-500, Minneapolis-Honeywell, Boston Division, Dept. 45, 1400 Soldiers Field Road, Boston 35, Mass.

MAGAZINE OF WORLD ASTRONAUTICS

m/r exclusive:

Report on Our Booming Missile Communities

a special service for m/r readers

During the last ten years a fabulous chapter in the book of American industrial expansion has been written. This is the story of our booming missile and rocket communities, the mushrooming test, research and development centers in the South, the West and the East. This is the story of the migration of scientists, engineers and military men to arsenals and bases that are sometimes hidden in a desert or on a tropical island. Sometimes they have sprung up out of nowhere: sometimes old war bases have been reactivated and small towns and communities have been completely re-erected and re-organized to keep up with the Klondike-type economic boom that has always followed.

The missile industry is coming of age. It appears to be separating itself from the aircraft industry and is about to outgrow it. In this respect, names like Patrick, White Sands, Redstone, Point Mugu, Palo Alto have become significant. In a period when we witness cutbacks in manpower and arms, when our aircraft and navel ship-building programs are being streamlined, missiles are zooming ahead. Because missiles form the backbone of tomorrow's defense, the missile industrial boom will continue. It probably will continue indefinitely, for it is our key to space flight and offers limitless possibilities.

A phenomenon of the missile and rocket industrial expansion in progress throughout the U.S. is the trend of many national nonmissile companies to establish plants in the new missile communities. Private contractors paving the way for small and large businesses, homes, schools, churches, follow in the wake of Army and Air Force bulldozers.

MISSILES & ROCKETS has followed this industrial boom closely, its editors having traveled thousands of miles to compile facts and figures on every major missile industrial expansion area, such as the areas around Patrick, Huntsville and others.

As a special service to our readers who might be considering moving across the country to any one of these missile Klondike areas, m/r introduces in this issue (next page) the first in a series of *complete analyses* of our missile communities. Our editors selected Patrick AFB and Cape Canaveral Auxiliary AFB as the first of this series because of their current importance as test sites for all three services and because the Air Force has just let new housing contracts in the area representing many millions of dollars.

U.S. Department of Commerce figures show that in the 10 years 1946-55 Florida led the seven Southeastern states in the amounts spent for new industries, with a jump of 110% from more than $50 million to upward of $105 million. Georgia came next with almost 100%, followed by Tennessee, 82%; Mississippi 72% and Alabama, 15.3%. The Florida Development Commission, in a recent report, lists 163 industries which, during the first half of the year, announced plans for new plants or expansion of existing plants, and this list does not include some of the more recent acquisitions such as Pratt & Whitney Aircraft Division of United Aircraft, The Martin Co., and others. Projected new plants and expansions run to $200 million or more.

In forthcoming issues m/r will present roundups on other missile communities. This *special service* is in accordance with m/r's editorial policy and is possible because m/r editors make it a point to travel extensively and get on-the-spot news and first-hand reports from the experts in the field.

The editors of m/r express their thanks to the U.S. Air Force and the Florida Chamber of Commerce, without whose assistance, this first roundup on Patrick AFB would not have been possible.

The Editors

m/r exclusive

PATRICK AIR FORCE BASE
today and tomorrow

By Erik Bergaust

PATRICK AFB—Stretching along more than 4 miles of highway A1A in Florida, Patrick Air Force Base occupies the beautiful land area between the Atlantic Ocean and the Banana River. The long, narrow installation is one of 13 Air Force missile test center activities and serves as headquarters for the group.

Originally built as the Banana River Naval Air Station, the post was deactivated after World War II, turned over to the Air Force in 1949, and renamed after Major General Mason Patrick, first chief of Army Air Services. The base covers 1822 acres and houses much of the administrative and logistical functions of the test center. Two runways are in operation at the field, one of 4000 feet and one of 10,000 feet.

Organization

Maj. Gen. Donald N. Yates, who probably knows more about missiles than any other military man in the country, assumed command of AFMTC in July 1954, after four years of research and development duty at Air Force headquarters. General Yates, a rated command pilot, has won the Distinguished Service Medal, Legion of Merit, and the Air Medal. His foreign decorations include the Degree of Chevalier in the French National Order of the Legion of Honor, the French Croix de guerre with Palm, the Degree of Honorary Officer in the Most Excellent Order in the British Empire, and the Ordem Militar de Christo of Portugal.

The General is a former president of the American Meteorological Society and a member of the Institute of Aeronautical Sciences and the American Rocket Society. He and his wife live on the base.

The deputy chief of staff for operations directs the center's programming. He makes policy, and provides program guidance and information for budget preparation. He is the watch dog of the center's activities when it comes to reprogramming and establishment of priorities. He decides what should be done and when. He also sets up liaison with foreign governments on down-range matters, directs staff intelligence activities and conducts the manpower and organizational programs.

The deputy commander for tests has charge of guided missile test planning. He controls engineering evaluation, data reduction, and photo lab facilities through the test engineering directorate. Official contact with the missile contractors is maintained through the project offices of the deputy commander for tests. He keeps in close touch with testing agencies' activities while at AFMTC.

Major General Donald Yates, USAF, Patrick AFB, Commander.

The deputy commander for range directs use of the AFMTC range. He makes policy on its use and on safety and sees that it is carried out. He assists the commander in supervising the activities of the range contractor and supervises the directorate of range operations and range development.

The deputy commander for support acts for the commander in administrative and logistical support operations of AFMTC. He commands the air base group and is designated base commander.

The director of range operations heads up communications, instrumentation, aircraft and range facilities in direct support of tests.

The director of range development controls all nonstandard range communications and instrumentation systems development for AFMTC. He supports and watches over the range contractor's development efforts.

The commanding officer of the 6550th Air Base Group is head man at Patrick Air Force Base and provides staff, administrative and logistical support to the command.

Missiles received at the center are handled by the 6555th Guided Missiles Squadron, which inspects, assembles and launches missiles. It also introduces military cadres to new guided missile programs and implements and evaluates firing procedures.

Logistical support for down-range stations and aircraft and crew support for the testing program is provided by the 6550th Operations Squadron.

Actual operation and management

of the various stations along the test range, including the launching site at busy Cape Canaveral, are the responsibility of Pan American World Airways and RCA. They maintain facilities and equipment and plan range operations to support missile test data. Various missile contractors have set up field stations for missile testing.

Other operating units at the base include Detachment 11, 4th Weather Group, responsible for forecasting and observing weather conditions in connection with missile launchings; the Patrick AFB detachment of the 7th district, Office of Special Investigations; the 2026 Airways and Air Communications Squadron; the Army Ballistic Missile Agency; and the Naval Ordnance Test Unit.

Down-Range Station

The AFMTC neither builds missiles nor fires armed missiles. It acts as a test facility and evaluation center for missiles of the three services. AFMTC provides the test range, assures the safety of the range area, and gathers information on missiles in flight. It then analyzes the data and determines whether missiles meet established requirements.

For several years, the AFMTC has been firing missiles from Cape Canaveral to the first island station on Grand Bahama, some 180 miles to the southeast. At about the center of the island is the Auxiliary Air Force Base, containing radio facilities, range clearance, inflight safety, weather reporting, telemetry reception, and radar and optical tracking equipment. Beyond Grand Bahama, other island stations are Eleuthera, San Salvador, Mayaquana, Grand Turk, Dominican Republic, Puerto Rico, St. Lucia, Fernando de Noronha and Ascension Island. Each station has both a military base commander and a civilian commander.

The Cape

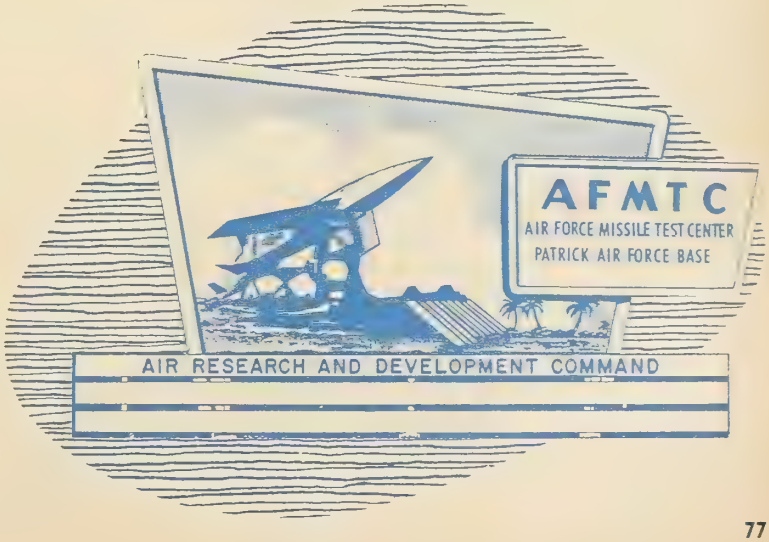
Cape Canaveral Auxiliary Air Force Base consists of 12,160 acres of government-owned land, 18 miles north of Patrick AFB. The area is cut off from the mainland by the Banana River and until recently, its only landmark was a lighthouse. Today, the site is as busy as any big air base.

Actual launching of missiles takes place at the Cape. The first launching from Canaveral was that of a V-2 on July 24, 1950. The operation of Cape Canaveral became the responsibility of PAA in March 1954.

Facilities at the Cape include launching areas with blockhouses, radio transmitter and receiver sites, telemetry receiver sites, radar, missile assembly buildings, guidance laboratories, LOX plant, photo-theodolite and camera sites, power supply buildings, motor pool, dining hall and fire station.

All activities at the Cape are coordinated at the central control building, three miles from the launching sites. It houses the range clearing and in-flight safety sections and the contacting center for all down-range stations. While in-flight safety functions are located at the Cape, this function may be transferred to any down-range station. There is a skid strip on the base for the recovery of missiles when possible. Normally, the missiles are impacted into the sea.

A submarine cable connects Cape Canaveral to the down-range stations as far as Puerto Rico and serves as a key factor in transmission of technical data during missile tests.



Housing

In addition to a few government quarters, there are 680 Wherry housing units (built and rented by a private concern) on the base. In the south Wherry area is a new primary school for the first through sixth grade for children whose parents live on the base. Congress has already approved 999 Capehart housing units for the base, and the Air Force has requested an additional 1000 units, bringing the total to 2679 housing units.

Construction of the 999 authorized units is expected to start soon. Bids have been submitted by various contractors and details of the arrangements are being worked out. In requesting more housing, the Air Force certified to the Federal Housing Administration that the base would be in operation for a longer period of time than that required for amortization of loans made in connection for the Wherry housing project. This means that the base will have to be utilized for at least the next 20 years. One Air Force Colonel put it this way, "The base is here to stay."

Air Force officials expect that about 150 houses will be ready within six months. These will be occupied as they become available. An additional 400 are scheduled for completion within a year, and the entire number within 18 months. The proposed housing area of about 300 acres will be connected to the base by an access road. Included in the plans, are a commissary, a chapel, and several recreation areas. The entire project is under AF supervision.

The individual houses will be constructed of concrete block and brick masonry, with terrazo floors and plastered walls and ceilings. Heating and air conditioning will be included in all

RANGE: The Air Force Missile Test Center operates the Florida Missile Test Range, the world's longest range for testing guided missiles. Bases are in operation or under construction along 5,000 miles of range from Cape Canaveral, Florida, southeast over the Atlantic to Ascension Island. Picket ships gather data between St. Lucia and Ascension.

units and each will have a garage. Many of the houses, and perhaps all, will have screened terraces.

The Capehart housing units will be for military personnel, who will be charged their quarters' allowance for use of the house with all utilities furnished. The housing quarters are being constructed under the government's policy of aiding free enterprise by contracting civilian companies for construction whenever possible.

Approval and guarantee of the construction mortgages will be processed through FHA channels from the Tampa field office. The contractor for the Capehart units will finance the project, while the AF will be tenants, making monthly payments until the mortgages are paid. The Air Force will then be sole owner of the housing.

In addition to the Capehart projects, the AF will buy the 680 Wherry units from their civilian owner. Patrick's Installations Office will begin a renovation process on the Wherry units and they will become quarters for military and civilian personnel at AFMTC.

Except during the peak of the winter season, small furnished apartments and rooms are in fair supply. The bulk of sale housing is newly built and attractively planned, mostly concrete block stuccoed, modern ranch-type units. Of the many housing projects under way in the area, most contain their own shopping centers. A list of real estate firms active in the area is available from the local chamber of commerce.

Present employment at AFMTC is about 15,500, compared to 1955's 8500 and 1950's 1500. By the end of 1958, the AF expects to have more than 18,000 employed at the base.

Of the 18 contractors at the base, about 12 are considered "major". The range contractors are Pan American World Airways and Radio Corporation of America. Others include Boeing Convair, Douglas, General Electric, Martin, Lockheed, North American, Northrop, and Ramo-Wooldridge.

Over 9500 of the base personnel are contractor personnel. Almost half of the total expenditures at the base in 1956 was spent in Florida, with 33 per cent being spent in surrounding Brevard County. The present AF payroll at Patrick amounts to about $6 million monthly.

The 225 separate parcels of real estate along the test range are the responsibility of the Air Force. Extending from the Florida coast to Ascension Island in the south Atlantic, the easements and right-of-way making up the 5000-mile range have been valued at a net worth of $335 million.

Schools

Public schools in surrounding Brevard County are operated on a full nine-month term. Approximately 5000 children from the Cocoa area are enrolled in eight local schools, and school bus service is available in all outlying areas. No tuition and all text-books are free. However, automobile owners are required to purchase Florida license plates if their children are enrolled in the state's schools.

The high school is fully accredited and offers courses in commerce, vocational home economics and industrial arts in addition to the regular academic courses. The county adult education program is one of the most progressive in the state and offers a variety of evening courses. It's enrollment is the fourth largest in the state.

Churches

The twenty-two churches in the Greater Cocoa area represent many denominations. Assembly of God, Baptist, Catholic, Christian, Christian Science, Church of Christ, Church of God, Episcopal, Lutheran, Methodist, Presbyterian and Seventh Day Adventist. Services for Jewish, Protestant and Catholic faiths are held at Patrick AFB. A complete list of churches is available from the local chamber of commerce.

Climate

Florida weather lives up to its billing: clear sunny days and pleasant cool nights. The area has never experienced sustained winds of hurricane force. A constant breeze blows from either the Banana or Indian rivers or the ocean. Elevation ranges from sea level to 81 feet. Almost all types of soil are found in the area although sandy loam is predominant and is suitable for the growing of many varieties of fruits and vegetables.

Here are some attractive figures from the U.S. Weather Bureau:

	Normal Temperature	Normal Rainfall
January	62.2	2.72
February	63.7	2.83
March	67.0	2.81
April	71.4	2.25
May	76.2	4.00
June	79.5	6.20
July	81.2	6.37
August	81.5	5.43
September	80.0	7.30
October	75.5	6.59
November	68.4	2.17
December	63.2	2.52

Health

Wuesthoff Memorial Hospital, a nonprofit community hospital located at Rockledge, is a modern, well-equipped fifty-bed hospital. In addition to facilities at Patrick AFB for base personnel, the Cocoa area has fourteen medical doctors, two chiropractors, four dentists, two optometrists, and one chiropodist. The Brevard County Health Department has offices in Cocoa with a resident medical doctor and a staff of nurses. A doctor is on call at the hospital at all times for emergencies, and a list of local doctors available for emergency calls, may be obtained from the chamber of commerce.

Water Supply

Water for Cocoa and Rockledge is secured from a clear lake through

waterworks owned by the city of Cocoa. Water is filtered, fluoridated and chlorinated. Capacity of the $485,000 plant is 2,115,000 gallons per day. Average consumption is 900,000 gallons per day. Water rates for Cocoa are: 5000 gallons or less, $2.50; over 5000 to 10,000 @ 30¢ per thousand; over 15,000 to 20,000 @ 25¢ per thousand; over 25,000 @ 20¢ per thousand. Water is inclined to be hard, but water softener is available.

Electric Power

The area around Patrick AFB and Cape Canaveral is served by the Florida Power and Light Co., which owns and operates the generating and distribution systems. The minimum electric bill in incorporated areas is $1.25, and in unincorporated areas, $1.50. Rates scale down to 1½¢ per kilowatt hour. Rate sheets will be furnished by the local office. The electric power is adequate and dependable.

Economy

Extensive citrus groves produce famous Indian River premium fruit, and the Cocoa-Rockledge area is the largest shipper of citrus gift packages in Florida. There are six commercial packing houses that pack carloads of fruit daily during the fruit season.

Vegetables are grown during the fall and spring and such sub-tropical fruits as mangoes, avocadoes, guavas, papayas, and bananas grow well here. Production of these on a commercial basis is increasing.

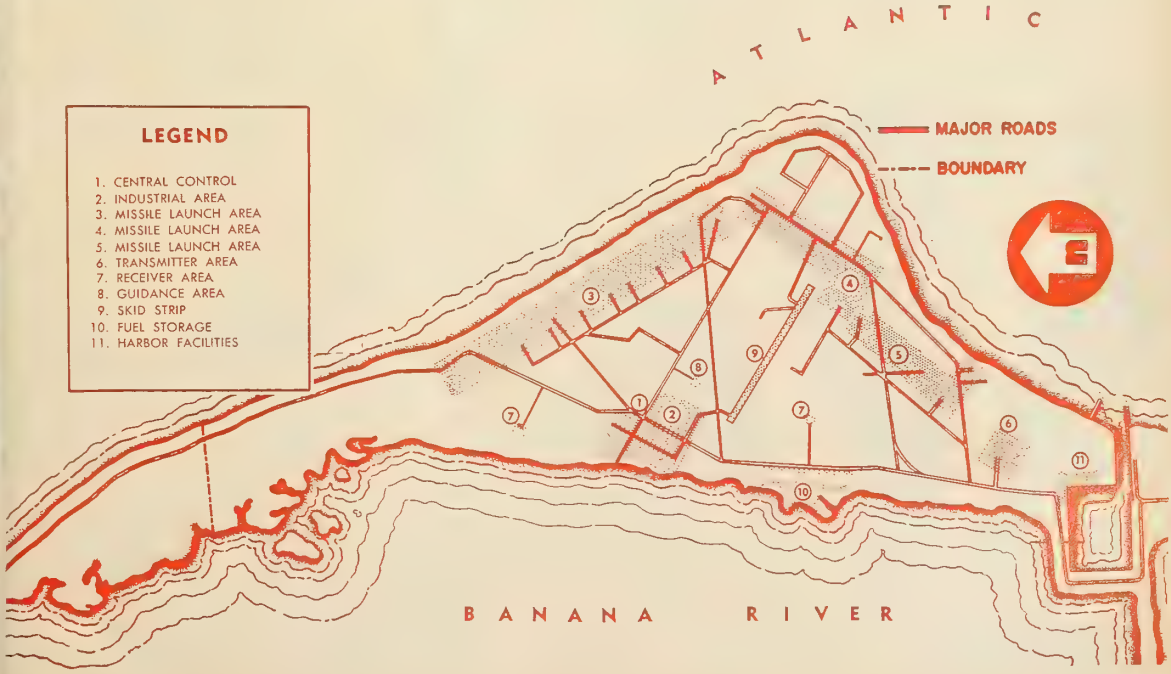
There is extensive beef cattle farming in the area and thousands of acres of land have been converted to improved pasture. Other agricultural activities include forestry, poultry, dairying, commercial gladiolus and gladiolus bulb raising, honey production, etc.

There is an abundance of sea food in commercial quantities, obtained from both the ocean and two nearby rivers. Fishing is a major industry, primarily shrimp.

Fishing and Hunting

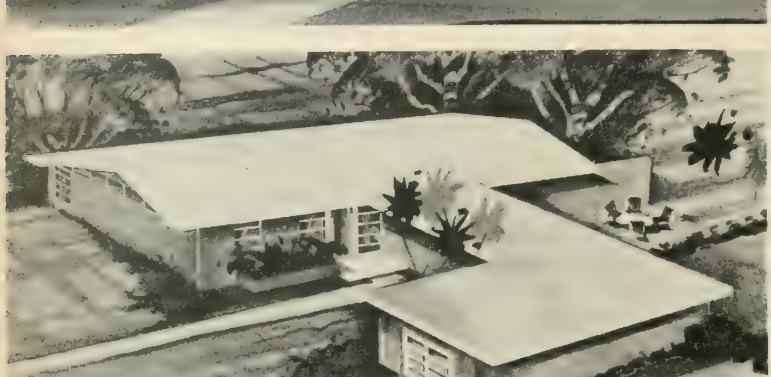
Fishing is probably the most popular sport of the area. The ocean, salt waterways, rivers and fresh water lakes in the vicinity attract fishermen from all over the country. Fishing licenses are not required for fishing in salt water. This includes the ocean, Banana River, Indian River, and Sykes Creek. The best fishing spots in the rivers are from banks or bridges and the most popular equipment is casting rod with level-winding reel or fly rod. Fish caught in the rivers are usually large.

Trout, drum, bass and snook are found in great quantities in the local rivers, while the ocean surf yields channel bass, blue fish, snook, flounder, weakfish (salt-water trout), pompano, drum, whiting, tarpon, sea bream, triple tail, sheephead and mangrove snapper.



A fishing license, costing $2.25 and obtainable at most boat rental and bait houses, is required for fishing in fresh water. Fishing for large-mouthed black bass is very popular in nearby fresh water bodies, such as Lake Poinsett, St. John's River, Lake Washington, and Lake Winder.

Duck and quail hunting is popular in this part of the state during the season, which lasts from about mid-November to the end of January. Deer and turkey hunting may be done on hunting preserves with a license obtainable from the State Game Commission. Local hunting requires a city hunting license.



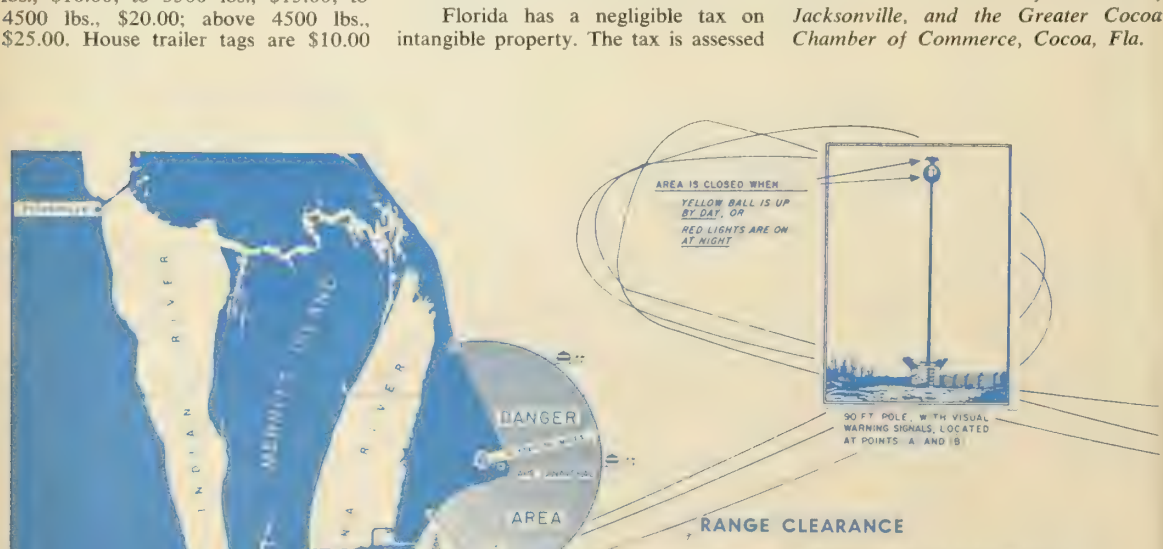
Taxes and Citizenship

Insofar as the state is concerned, a new resident of Florida is a citizen of Florida (a resident being a person domiciled in the state). One is not eligible to vote, however, until he has resided in the state one year and in the county and precinct six months. Declaration of intention to become a citizen may be filed in person by a new resident in any courthouse. Florida has no poll tax.

Florida has none of the penalizing taxes now common to most states. Its constitution prohibits the state from imposing taxes on incomes (either individual or corporate) and on real property and permits no state inheritance tax, although sharing in that which is federally imposed. The state's finances originate solely from excise and sales taxes, occupational and other licenses of the usual character. The state sales and use tax is similar to that in effect in the majority of other states. Exempt from sales tax are: food,

Beautiful, modern Capehart housing units for Patrick AFB airmen.

medicine and some farm supplies.



There is no property (ad valorem) tax in Florida on automobiles, but the state imposes a license fee as follows: weight up to 2000 lbs., $5.00; to 2500 lbs., $10.00; to 3500 lbs., $15.00; to 4500 lbs., $20.00; above 4500 lbs., $25.00. House trailer tags are $10.00 when it is used on the highway; when used as a home, it is taxed as personal property (see below). Nonresidents, entering children in public schools, are required to purchase Florida tags for automobiles used in the state.

Florida has a negligible tax on intangible property. The tax is assessed at full value and is 10¢ per $1000 on money and $2.00 per $1000 on stocks, bonds, notes and mortgages. This tax does not cover savings bonds.

Occupational and business licenses are required by the state, counties and cities. Other city and county taxes are difficult to compile because of the variety of conditions, localities, etc. To secure information on these various local taxes, the Florida Chamber of Commerce suggests writing to the tax assessor in both the city and county in which you are interested, regarding the following subjects: Real Property: Counties and cities levy property (ad valorem) taxes, but may not tax a homestead except where the assessed value is over $5000, and then only on that part exceeding this minimum. Personal Property: These are city and county taxes and there is a $1000 exemption for the heads of families.

Taxation in the Patrick AFB locality are approximately as follows: Taxes on nonhomestead-exempt property in Cocoa, 10 mills; state and county 61.85; in Rockledge, 9 mills; state and county, 70.35. On homestead-exempt property in Cocoa, 2.7 mills; Rockledge, none; state and county, none. Property is evaluated at about half its sales value.★

Facts, figures and illustrations in this article have been compiled and digested by m/r from material and statistics furnished by the Air Research and Development Command, Office of Public Information, HQ, Patrick AFB; The Florida Chamber of Commerce, Jacksonville, and the Greater Cocoa Chamber of Commerce, Cocoa, Fla.

RANGE CLEARANCE

Crash boats also patrol the area and warn small craft. Also cleared of ships is the area "downrange" where the missile impacts in the water. The section between the five mile danger zone around the Cape and the impact site is monitored by aircraft and radar to insure the safety of any shipping in the area. On the basis of reports from all these search units the range clearance officer determines the safety involved and authorizes the launching.

WHY ASTROPHYSICS?

Astrophysics applies the laws of physics to the study of the universe, according to the dictionary. But only the history book reveals that it was the study of the universe which gave impetus to the development of physics. The basis of all science is precision measurement. However, without the universe around us such concepts as precise time and precise position may never have evolved.

The ancients observed the regular motion of stars, caused by the earth turning on its axis—uniformly, with hardly any variation in the 24-hour period. Nowhere on earth do we have an example of such uniformity.

If we look at the history of astrophysics, we find a number of breakthroughs. Some are related to the development of new instruments, others are theoretical in origin. Our ideas about the nature of the universe are based on what we see and the better we see, the greater our understanding.

The first and most important breakthrough was the invention of the telescope which, in the hands of Galileo, led to the first real discoveries in astronomy. In his "Sidereal Message" Galileo describes very excitedly the "many great wondrous spectacles" which he saw when he first picked up his telescope.

His first discovery—the mountains of the moon whose height he measured very crudely; his next discoveries—the moons of Jupiter and the phases of Venus, which proved that other planets have satellites and also give great impetus to the Keplerian solar system theories.

Galileo was the first man to view the Milky Way and recognize that it is made up of countless stars. Larger and larger telescopes have evolved up to the 200-inch Mount Palomar instrument which now looks far out into space. Here in 1610, physics, for the first time, advanced astronomy.

The stimulating effect of the astronomical discoveries on physics itself must not be overlooked. Nowhere on earth are there phenomena as regular and therefore as simple as in the workings of the universe, especially in the solar system. Objects on earth never move under gravity alone. There are always winds, air friction and other disturbing elements.

It is no wonder that Newton formulated the simple law of gravitation (in 1666) through astronomical observations and only later applied it to phenomena on the earth. Now we use it to describe the motion of earth satellites, and ballistic rockets moving freely outside the atmosphere under the influence of the earth's gravitational field alone.

The next great advance was the invention of the spectroscope, the instrument which can analyze the light from celestial objects after it has been collected by a telescope. It is the instrument which tells us what kinds of atoms contribute to the light.

The spectroscope, first in the hands of Kirchhoff who in 1862 applied it to the sun, has been and still is the most important tool of the astrophysicist. It has been used to deduce the composition of stellar atmospheres and of interstellar gas.

It can tell us the temperature of the earth's atmosphere and the nature of the surface of Mars and Venus. Spectroscopy, however, really became valuable only after the development of modern atomic physics, which provided the key to why atoms emit light of particular colors and with particular intensities.

Nuclear physics has also found its application to astronomy, and a very important one. It has given us a means of understanding the ultimate energy sources for the stars. We now know what the interior of the stars consists of, the relative abundances of hydrogen and helium and of the heavier elements and we can calculate how rapidly these materials are burnt up in order to provide the energy.

We can even calculate the evolution of stars, their past behavior and past energy output and we can predict their future behavior and their eventual death. As a result of our increasing knowledge of nuclear physics we now know more about the internal constitution of stars than we do about the internal constitution of the earth itself.

The development of radio astronomy was a major breakthrough closely tied to the technological developments of electronics. We can now "see" objects in space through radio waves.

They are not subject to absorption by interstellar dust which limits the visible light radiation. We can, therefore, look much farther into the region of the galactic center than we can with optical telescopes. And we can get new data on celestial objects by studying their emission of radio waves.

There have been discoveries of new objects, such as the radio stars which are slowly being identified. There has also been much activity in the science of magnetohydrodynamics, one task of which is to explain the production of radio noise in the universe as well as cosmic ray origins.

But these advances are only the beginning. A new tool of technology has arrived which will push astrophysics on to greater horizons—the rocket. Already high-altitude rockets have made pioneer explorations above the ocean of atmosphere which screens up from most of the radiation coming from outer space.

We have already been able to "see" the sun in its ultraviolet light but only for short periods. The artificial satellite will eventually allow long-term observations of solar ultraviolet and X-rays. The *Vanguard* project will be of major importance for astrophysics. So will extensions of the vertical rocket techniques to extremely high altitudes.

The recently announced Project *Far Side* will carry instruments to unbelievable altitudes, measured in earth radii, and eventually to the limits of the earth's gravitational field. To begin with, these observations will be crude and rather simple, but as larger rockets are developed the vehicles will become heavier and more intricate and the instrumentation carried out into space will become more elaborate.

In the meantime, the study of the universe may give us another insight into physics. Cosmology may solve the most fundamental problems of all; gravity and the ultimate nature of matter. The steady-state model of cosmology which assumes that matter is created spontaneously and uniformly throughout space may in the end allow us to glimpse the properties of subnuclear matter and of antimatter.

Already theoretical speculation is rife on whether antimatter obeys the same laws of gravity as ordinary matter. But this is a hypothesis which we may never be able to test in the laboratory. For confirmation we must look to the cosmos itself.

1957 Liquid Propellant Round-up

By the Editors of m/r

BY THE TIME our GALCIT Project had formed and actually got under way, the Germans had a head start in liquid propellant rockets. By 1931 a 660-lb. thrust liquid engine had been developed in Germany, and by 1934 a rocket using this engine was successfully launched. Peenemuende had developed a 3300-lb. thrust engine by 1939.

It was not until 1939 that the Jet Propulsion Laboratory undertook the development of liquid propellants. On July 1, 1940, JPL started work on nitric acid systems. The aim: develop a liquid propellant rocket to deliver 1000 pounds of thrust for one minute. Starting with gasoline as fuel, ignition problems and combustion instability were encountered (the engine worked properly about 80% of the time).

At about the same time, a group of researchers at the Naval Experiment Station (Annapolis, Md.) also had the same combustion trouble with a nitric acid-gasoline combination. It was found that aniline was spontaneously combustible (hypergolic) with red fuming nitric acid.

In April, 1942, an A-20A attack bomber was equipped with a 1000-lb. thrust acid-aniline rocket. During the tests some 44 successive runs were made without any misfires or explosions. This marked the first liquid propellant rocket assist takeoff (RATO) in the U.S.

After the successful RATO, Aerojet Engineering Corp. (now Aerojet-General) took over to manufacture liquid units. However, liquid engine use was dwarfed by the efforts devoted to solid RATO and artillery rockets.

A Signal Corps assignment in 1944 required a rocket to carry 25 pounds of meteorological instruments to an altitude of at least 100,000 feet. JPL started to work on this project by first firing a missile booster *(Baby WAC)* in July, 1945. Test of the *WAC Corporal* was made in autumn 1945. The engine, delivering 1500 lbs. thrust for 45 seconds was an acid-aniline engine built by Aerojet.

One of the world's more highly developed liquid rocket engines—Reaction Motor's power plant for the North American Aviation X-15 rocket research plane undergoing static test.

On the East Coast the scene was somewhat different. A number of ardent American Rocket Society members (Lovell Lawrence, Jr., James H. Wyld, John Shesta, and Franklin Pierce) had been conducting Sunday afternoon rocket shots. They formed Reaction Motors, Inc. in 1941 and by November, 1942 successful runs were made at over 1000-lb. thrust. They upped this to 3400 pounds by May, 1943.

The end of the war, however, showed that the U.S. was lagging far behind in development and production of large liquid rockets. The V-2 was immediately accepted as the workhorse around which additional developments nucleated. There then followed a growing number of government, industry, and research groups (Tables 2, 3 and 7). A rundown on the latest activities follows:

AEROJET-GENERAL CORP. Working on the *Titan* (LOX), second-stage *Vanguard* (acid) liquid rockets. Also *Aerobee-Hi* (acid) and liquid underwater units (lithium). Now building three acid-JP rocket sleds.

AMERICAN MACHINE & FOUNDRY CO. Working with ethylene oxide and alkyl nitrates for ICBM APUs at its Pacoima, Calif., facility.

AMERICAN ROCKET CO. Recently entered the liquid rocket field with a new monopropellant combination. Also working on new high energy fuels.

ARMOUR RESEARCH FOUNDATION. Extensive research work on stabilization of liquid ozone. Also: chemistry of the boron exotic fuels.

BELL AIRCRAFT CORP. Developed powerplant for *Nike Ajax* (acid) and liquid rocket for *Rascal.*

CALIFORNIA RESEARCH CORP. Working toward improvement of properties of nitric acid systems.

CURTISS-WRIGHT CORP. Developed a LOX-gasoline ATO and a throttleable motor for Bell X-2. Thrust is 12,000 pounds. Major propellant emphasis: LOX.

ETHYL CORP. Doing research in development of monopropellants and fuels. Products: alkyl nitrates and alum-

TABLE 1

ON THE SHELF LIQUID ENGINES

Model	Length (Overall) (in.)	Diameter (Maximum) (in.)	Weight (Dry) (lb.)	Thrust (lb.)	Burning Time (sec.)	Mfr.	Oxidizer	Fuel	Notes
Aerobee-Hi				4,100	53	A	NA	XY	Niafrak nozzle, ceramic lined.
AJ24-1 (YLR45)	74	30			45	A	NA	JP	B-47 RATO (2 retractable chambers on each side of fuselage).
AJ-10-24	130	15				A	NA		*Aerobee* liquid booster.

Jupiter				135,000		NAA	LOX		*Jupiter* engine.
Titan				300,000		A	LOX		Booster.
				60,000					Sustainer. *Titan*.
TPM			4,250	50,000	8	RMI	HP	JP-4	Transonic pusher engine for Edwards track, uses 3.
				150,000					
SPM			14,300	62,000	9	RMI	HP	JP-4	Supersonic pusher engine for Edwards track, uses 8.
				500,000					
AJ10-28	160			35,000		A	RFNA	JP-X	SNORT engine, uses 1.
AJ10-36	196			35,000		A	RFNA	JP-X	SNORT engine, uses 1.
AJ10-33	233			35,000		A	RFNA	JP-X	SNORT engine, uses 3.
				105,000					
X-15				60,000	60-180	RMI			Motor for NAA X-15.

A: Aerojet-General.
RMI: Reaction Motors, Inc.
NAA: North American Aviation.
R: Ryan.
C-W: Curtiss-Wright.
B: Bell Aircraft.
GE: General Electric.
UDMH: Unsymmetrical dimethyl hydrazine.
RFNA: Red fuming nitric acid.
HP: Hydrogen peroxide.
JP-4: Kerosene.
ALC: Alcohol (ethyl).
XY: Xylidine.
NA: Nitric acid.
LOX: Liquid oxygen.
JP-X: 40% UDMH, 60% JP-4 with aniline-furfuryl alcohol starter fuel.

inum organics.

EXPERIMENT, INC. Engaged in research on liquid propellants.

FOOD MACHINERY. Its Becco Div. is a major supplier of high strength hydrogen peroxide while Chlor-Alkali Div. supplies UDMH fuel.

GARRETT CORP. Has specialized in liquid APUs (viz. alkyl nitrates).

GENERAL ELECTRIC CORP. With research in all phases of propulsion, GE's major propulsion task is to develop and produce first-stage *Vanguard* engine (X405). Operates large static test stand at Ballston Spa, N. Y. Major propellant emphasis: LOX.

LOCKHEED AIRCRAFT CORP. Now developing its own central California research facility and construction of large-scale static test facilities.

NORTH AMERICAN AVIATION, INC. Big gun in liquid rocket field, has liquid powerplants for *Atlas, Navaho, Redstone*, and *Thor*. Operates huge stands in Santa Susana Mountains. Building *Atlas* engine plant at Neosho, Mo. Major propellant emphasis: LOX.

OLIN MATHIESON CHEMICAL CORP. Now aligned with RMI under OMAR program. Major propellant tasks: production of hydrazine and derivatives, and Zip fuels.

PENNSALT CHEMICALS. Pushing development of fluorine and fluorine chemicals for liquid rockets.

REACTION MOTORS, INC. Active in liquids for aircraft propulsion, ATOs, and launching systems. Also working on two large rocket sleds for Edwards AFB track.

RYAN AERONAUTICAL CO. Producing *Corporal* rocket engines.

WYANDOTTE CHEMICAL CORP. This producer of ethylene oxide is now entering production of auxiliary propulsion systems using this material.

Liquid Status

During the twenties, thirties, and early forties of this century, the basis for all our liquid rocket systems was established. There was Goddard and the VfR with liquid oxygen, Walther, BMW, and JPL with hydrogen peroxide and nitric acid. With the exception of hydrogen peroxide, the LOX and acid systems power all our present "modern" liquid rockets. Of these combinations, LOX has emerged as the liquid king.

It may seem incredible that our *modern* missiles are powered by *ancient* propellants. Modern solid systems, a scant ten years old, are competing hard and heavy with these liquids in performance, scale-up, and reliability. The difficulty has been not so much in the inadequate liquids themselves but in finding better replacements. Thus, because of the lead time required for new systems, these present liquids, as bad as they are, simply could not be dropped.

The properties of the liquid twins (LOX and nitric acid) have been known for some time (and this includes performance characteristics). Continuing

efforts have gone into improving and enhancing properties. However, most of the efforts have gone into time-and dollar-consuming engineering—that is, translating an expanding propellant system into an expanding missile system.

LOX is now the undisputed liquid king. Its realm is the IRBM, ICBM and the first-stage *Vanguard*. Although performances have been increased some 50 seconds since World War II, the greatest triumph has come in the evolution of mighty engines.

Both government and industry feel that these large engines will probably form the propulsion basis for man's first real trip into space—at least for establishing the manned satellite and the first rocket to the moon. However, it has cost us ten years to do this. It may be another ten years before liquid ozone or fluorine systems start displacing LOX.

The hot-tempered nitric acid systems have not been so regal. Nitric acid has had early favor. For example, the *Nike* (now *Nike Ajax)* liquid system was ready about ten years before the overall system (including guidance) caught up with it and was ready for operation. This overall systems difficulty has been responsible for the slow liquid progress.

Although the bugs in the acid systems had been pretty well worked out by the Germans, it remained for us to inherit two major difficulties. One, the matter of scale-up, is now near solution. The other—storage and handling—is about to put nitric acid systems into the "use as soon as possible" category.

One major lag in the advancement of liquid systems has been the failure to evolve a *practical* monopropellant suitable for primary propulsion of large missiles. All present monopropellants, hydrogen peroxide, alkyl nitrates, tetranitromethane, and ethylene oxide have failed for big unit consideration. Only one, hydrogen peroxide (as a bipropellant system), is now going into a medium-thrust engine. The rest of the monopropellant lot have turned to the gas generator realm for their continued existence. Thus, a major breakthrough is needed to stimulate the monopropellant picture.

Hardware developments have come as a result of slow-plodding rather than breakthroughs. Thus, the thrust levels have gradually crept up. Ten years ago, the 35,000-lb. thrust V-2 engine was a monster. Today's ICBM engines produce thrust at about four times this level. However, the average liquid rocket (viz., the IRBM and the two liquid *Vanguard* engines) operate at much lower levels. Thus, by grouping or modifying existing engines using existing liquids, our hardware needs may be solved for future applications.

As the newer propellants come along they can be evaluated and applied in available engines with or without modification. Liquids have established a good growth pattern that has not been duplicated in solid engines.

Although liquid rockets have established a scale-up technology and have also provided for performance increases, the handling and reliability problems will continue to plague liquids.

The handling problem of liquids, bad as they now are, may tend to worsen with the two potential oxidizer contenders—ozone and fluorine. Both can be handled safely but require extreme care. Whether these two can be engineered to a "GI-proof" status is difficult to say. However, improvement of the handling characteristics may already be under way in classified work.

Despite handling improvements, it is doubtful if ready-to-go, long-storage capabilities comparable to the new solids can ever be expected. The liquids have only been favored where the highest performance is the most important parameter.

It is in the reliability department that even the best possible liquid systems can be considerably improved. Present reliabilities are on the order of 95-97% with the hope that 98-99% can eventually be achieved. For manned craft even this may not be enough. It should be noted that the U. S. still is only in the research vehicle stage in its liquid propellant rocket aircraft.

What of the ultra-energy liquid systems such as free radicals? Although research in this field is still embryonic, it is unlikely that handling will be materially improved. As a matter of fact, it looks like the solid and liquid fields will merge here—solid storage and liquid or gaseous use.

The applications picture for liquids is such that they will continue to grow but are lagging somewhat in the specialized race with solids. Of course, the future applications for all rocket power are expanding at such a rate so that it would be hard to say whether solids or liquids would be winning sales-wise ten years from now.

The liquid rocket industry has accomplished a herculean task—translating the hot laboratory combinations into workable systems. Now that the pattern is established, liquids will continue to push toward the limits of chemical propellants.

TABLE 2
GOVERNMENT LIQUID ACTIVITY

Group	Location	Activity
Air Force		
Flight Test Center	Edwards AFB, Calif.	Rocket aircraft and test stand work.
Holloman AFB	Alamogordo, N. M.	Flight tests.
Missile Test Center	Cocoa, Fla.	Static & flight tests.
Wright ADC	Dayton, Ohio	Propellant evaluation & static testing.
Army		
Redstone Arsenal	Huntsville, Ala.	Propellant evaluation & static testing.
White Sands Proving Ground	White Sands, N. M.	Flight & static tests.
NACA		
Lewis Flight Propulsion Lab.	Cleveland, O.	Propellant evaluation.
Navy		
Air Rocket Test Station	Dover, N. J.	Large test stand.
Missile Test Station	Point Mugu, Calif.	Flight tests.
Ordnance Test Station	Inyokern, Calif.	Research & development.

Liquids Growing

During World War II and the bustling period immediately afterward, about $1 billion went into liquid propellant rockets. In the ten years since the war another billion has been spent. At the present time, the liquid rocket business is worth about a billion per year, and it may double in another two to five years. Unofficial estimates break down the annual liquid rocket industry as follows:

	Millions
Nose cone, payload, and guidance	$650
Airframe	100
Powerplants	100
Propellant chemicals	100
Other chemicals and materials	25
Miscellaneous	25

This includes research, development, production, training and testing, and maintenance.

In addition to the industry lineup

0.5H+1H	1040
H (alone)	1280

The tables on this page present the U.S. liquid rocket industry in a statistical nutshell. Listed in Table (3) above are 21 companies in the liquid propellant rocket business. All-told they have offices and facilities at 34 locations around the United States. Their activities range from work on gas generators with a few pounds thrust to ICBM motors whose thrust runs into the hundreds of thousands of pounds. If any doubt still remains that the chemical industry has a big stake in the business of missiles and rockets, Table (4) should dispel it. The other two tables give an idea of what's in store for the future.

shown in Table 3, most aircraft firms are engaged in various rocket activities. This trend has recently spread to the automotive and chemical industries. The employment force for liquids, therefore, is much larger than for the solid rocket industry.

When all supporting personnel (including administration and research) are included, an estimated 100,000 to 200,000 people are working on liquid missiles and rockets. In two years the figure may increase by another 25,000 and in five years the total force may be near 500,000. Most of the new personnel will be coming from colleges and universities and from the aircraft, automotive, and chemical industries.

Table 4 lists some of the major liquid oxidizers and fuels going into rockets. Major efforts are now going into LOX expansion since all the ICBMs and IRBMs will use this oxidizer. Production of liquid fluorine and ozone is still very small. Nitric acid capacity is still far ahead of use (as is the case for liquid ammonia); however, use of nitric acid seems on the downgrade. Other oxidizers are being made and used only in very small amounts. Petroleum-based fuels are still far out in front over others and still increasing in use despite the new HEF entries.

Hardware Heavy

Since the war a large amount of hardware has become available (Table 5). Thrust levels range from the early 4000-lb. ATO units to the 135,000 ballistic missile booster engines. Burning time ranges from 8 to 180 seconds. It is thus probable that the designer now need not look for completely new engines for future applications.

On the shelf rocket engines are available even for the beginnings of space flight. Tried and proven engines may be clustered or staged to give almost any desired thrust program. Not only will today's liquid rocket engines help to establish the first earth satellite, but it is predicted that they will:

1) establish a manned satellite,
2) impact the moon,
3) make an unmanned circumlunar flight.

Limit Near

Despite the many possible liquid oxidants, only LOX, peroxide, and nitric acid systems have large-scale application. Of these, only LOX systems give the highest performance, at the price of non-storability and messy handling.

Nitric acid, though manageable, gives rise to a host of handling and storing problems. It now looks like acid systems are on the way out. Peroxide, costly and heretofore relegated to auxiliary propulsion, is hanging in the balance. Present liquid systems are now at the 220-240 sec level. And solids are already nipping at liquids in this range.

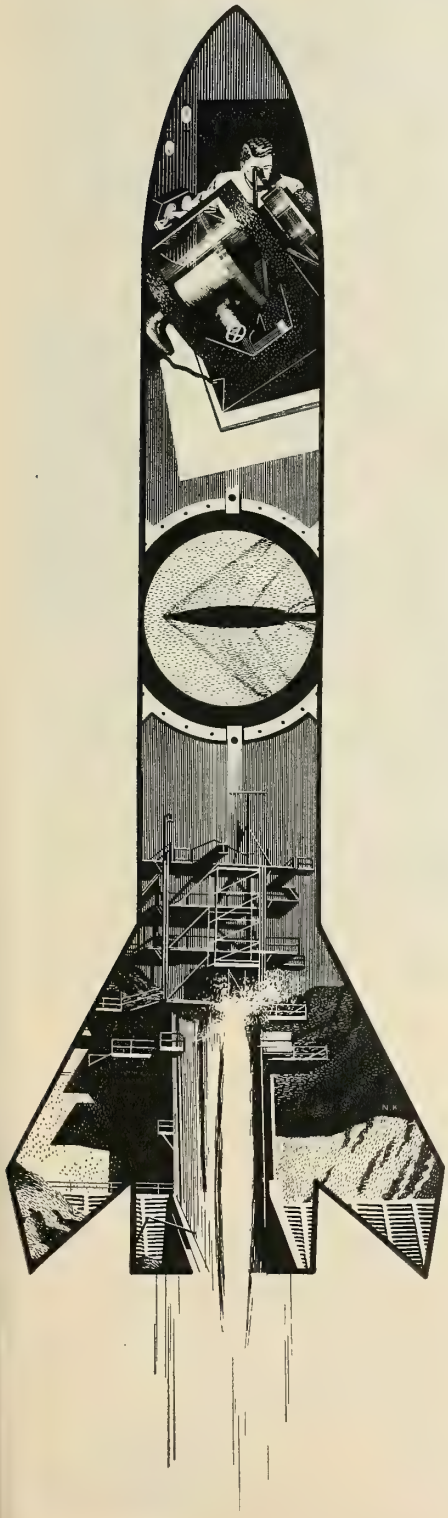
What of the new line? There does not appear to be any breakthrough in storage and handling of the new high-energy combinations. Therefore, the big push will be for performance. The liquid people are hanging their hats on two techniques for raising specific impulse.

By using hotter burning fuels and building hardware which can take care of higher temperatures and pressures, an upping of some 25-50 seconds may result. A more promising technique will be to switch to new oxidizers.

Research is now under way with the two most promising prospects—fluorine and ozone. Both may put the liquid rocket near the limits of chemical propellants. Thus, an increase of some 50 seconds may be in the offing (Table 6). This push will be a long and costly one. It won't come in a year but may be with us in ten years.

Liquids have managed to keep ahead of solids by virtue of only two major parameters—scale and performance. Solids are now scaling up fast. Liquids can thus keep ahead only by keeping ahead in performance. With this stimulus the picture should prove very interesting.

In the future the greatest hope for a propulsion breakthrough lies in free radicals or nuclear processes. In free radical propulsion, fragments of chemical molecules recombine to form the original molecules, with heat releases much greater than conventional combustion processes (Table 6). For example, combining atomic hydrogen to give molecular hydrogen could give some 90,000 BTU/lb.



The big problem in free radical propulsion schemes seems to be twofold: storage in large amounts (present technique is to cool to near absolute zero) and the high temperatures of recombination (up to 12,000°F). Then, fission one pound of uranium ^{235} gives off about 1 billion BTUs and in expanding hydrogen could give a theoretical I_{sp} of about 900 seconds.★

TABLE 7

LITERATE LIQUIDS AT THE UNIVERSITIES

University	Activity
California Institute of Technology Pasadena, Calif.	With the Jet Propulsion Laboratory, the student has an opportunity to work in the missile field while learning. JPL also carries out an extensive program in all areas of liquid propellants—research, development, and testing.
University of Detroit Detroit, Mich.	Operates Missile and Rocket Section. Offers student training and conducts research projects in liquid propellants.
Johns Hopkins University Baltimore, Md.	Operates the Applied Physics Lab. at Silver Spring, Md. APL is active in research, development and testing of liquid rockets.
Massachusetts Institute of Technology Cambridge, Mass.	Has available a static test facility operated by MIT Rocket Research Society.
University of Michigan Ann Arbor, Mich.	Operates a propulsion laboratory for liquid rockets.
Ohio State University Columbus, O.	Research and development of premixed propellants and liquid hydrogen rockets.
Princeton University Princeton, N. J.	Its Forrestal Research Center administers Project Squid. Has static test stands and is doing work on liquid ozone.
Purdue University West Lafayette, Ind.	Rocket laboratory conducts research in liquids—mainly nitric acid systems.

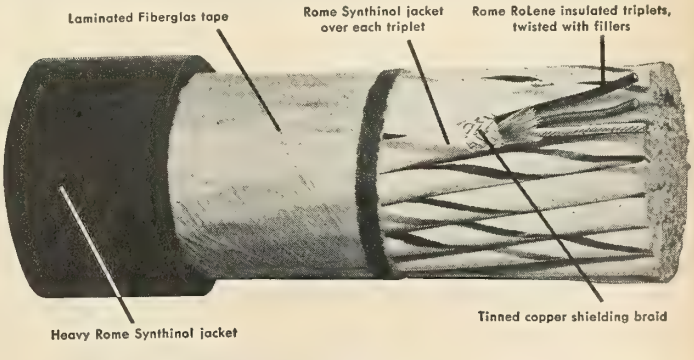
Special 111-conductor Rome cable solves tough guided missile problem

When project engineers at North American Aviation, Inc., needed a special telemetering cable for their advanced guided missile work at various missile test centers, Rome Cable Corporation was asked to make it.

The cable was a tough one to manufacture. The specifications called for exacting dielectric requirements, low-loss characteristics, adequate service life—and a total of 111 conductors—all contained by one heavy-duty jacket.

Because Rome Cable engineers are accustomed to solving tough cable problems like this, they readily produced the cable which met North American's rigid specifications. Rome RoLene—a polyethylene compound—proved perfect for insulating the 37 triplets inside the jacket, and it easily met the specification requirements calling for controlled capacitance and uniform wall thickness. Rome Synthinol, a tough polyvinyl chloride compound, proved to be an excellent jacket material.

Rome Cable can also help you



You can turn to Rome Cable with confidence for the right solution to *your* special cabling problems. Rome's competence in its field is, in part, a function of the following factors:

1. Engineering experience. Rome engineers regularly handle complicated specification problems. They've had years of experience dealing with electronic circuit problems.

2. Complete production facilities. The completeness of Rome Cable's manufacturing facilities is unique.

3. Uncompromising quality control. Latest devices, like the photoelectric gauge, are regularly used to assure highest quality. This particular gauge enabled Rome to maintain an exacting control on the diameter limits of insulations and jacket for this special cable.

Rome Cable's engineers can probably be of real help to you on your next cable problem, especially if it is a really tough one. For more information as to what we can do to help you, simply contact your nearest Rome Cable representative—or write to Department 850, Rome Cable Corporation, Rome, N. Y.

Variety—you can choose from a wide range of finishes for magnesium

Smart, modern furniture is just one example of how finishes for magnesium are widening design horizons. Whether for appearance, protection, or a combination of both, the right finish is available. Magnesium can be painted, chemically treated, electroplated, and coated with plastic or rubber.

To meet the rigorous standards set by the aircraft industry, there are air dried and baked paint finishes with excellent adhesion, maximum imperviousness and good wear resistance. Various types of chemical pickling provide the right paint base. Anodizing provides exceptional corrosion, heat and abrasion resistance. In addition, any metal which can be applied by electroplating may be deposited on magnesium.

What about your products? If you're not making use of magnesium lightness, strength and durability—and the variety of finishes for magnesium—there's no better time to start than right now. Contact your nearest Dow sales office or write to us for more information. THE DOW CHEMICAL COMPANY, Midland, Michigan, Department MA 1405G.

Propulsion Engineering

By Alfred J. Zaehringer

BORON FUELS: A BILLION DOLLAR MARKET in ten years is the prediction by Olin Mathieson. OM's $5.5 million pilot plant is now delivering high energy fuels to USAF. Second plant, three times present size, will be "on stream" this year. Third plant ($36 million) will start operating by end of 1959. OM is said to be shooting for a fuel price of $1/gal. in ten years. Meanwhile, there is talk that Olin and U.S. Borax will get together and form a company for research and production of boron and lithium compounds.

NEWEST BORON COMPOUND is trimethyloxyboroxine. Anderson Chemical offers the liquid—containing 18.7% boron—in carload quantities. Suggested applications include: jet fuel additive, neutron detector.

ATOMIC OXYGEN, found at high altitudes, could be used as a super "fuel" by jets or ramjets, says USAF. Cambridge Research Center has found a catalyst which kicks atomic oxygen into molecular oxygen with a large energy release.

CHLORYL FLUORIDE has been prepared and studied by chemists in Argentina. The compound, ClO_2F, is a powerful oxidant. A similar oxidant, perchloryl fluoride (ClO_3F) is available in pilot plant quantities from Pennsalt.

DIRECT MEASUREMENT OF ROCKET EXHAUST VELOCITY has been developed at Ohio State University. Seven optical probes are used with a 10 meg, 6-channel chronograph to measure time (in steps of 0.1 microsecond) for a luminous wave to pass between probes. The system is calibrated by means of a gaseous mixture of known detonation velocity. Good checks have been made when compared to other measuring systems.

NOW A ROCKET ENGINE FOR STUDENTS. A group of Aerojet-General engineers have built the "Spark I," LOX-watered alcohol rocket engine of 400 lb. thrust. The regeneratively-cooled motor has an I_{sp} of about 227 sec. and is designed primarily as a training tool.

CARTRIDGE ACTUATED DEVICES using solid propellants are in for study and test by Microloc Corp. of Los Angeles. The Army Ordnance contract comes from Frankford Arsenal. The Conax Corp., Beckman-Whitley, et al. have long been producing explosive actuated valves for missiles. Now a new entry: Atlas Powder Co. is producing a squib-actuated missile switch.

MORE SOLID PROPELLANT ACTIVITY in the Midwest. Standard Oil Co. (Ind.) is expanding lab facilities at its Seymour, Ind. (USAF Freeman Field) plant; completion date is this fall. Olin Mathieson is adding to its high-energy solids facility (Ordhill Works) at Marion, Ill. Propellex Chemical Corp. has moved to a 100-acre site at Edwardsville, Ill. The facility will permit preparation of ammonium nitrate and cast double base propellants to grain sizes of up to 250 lbs.

SHIELDING OF PROPULSION REACTORS is still a big problem. While boral or the boron stainless steels do cut off neutrons, they are still transparent to gamma rays. Even the lead plastic compounds, effective gamma shields, are not the optimum for airborne use because of the very high density. There are now indications that metal-organics or complex organics in combination with light metal carriers may prove effective gamma-ray shielders.

RESEARCH ON FROZEN FUELS has been reported. The technique is to freeze a gas (such as hydrogen) and to use solar energy to melt and evaporate it into a combination chamber. Such frozen fuels might be conveniently stored in space (near absolute zero) and used for space rockets. Work is also underway in determining the physical properties (tensile and compressive strength) of such "iced" materials at these very low temperatures.

ANTI-MATTER may be possible. Just as anti-particles exist for electrical matter, some scientists have theorized that a negative gravitational matter concept may explain several analomies in existing theories.

m/r's personal report from . . .

Rocketeer Sam Hoffman

For Big Jobs Re-use or Controlled Flight Liquid Rocket Engines Now Lead the Field

Manager of North American Aviation's Rocketdyne Division and a member of the American Rocket Society's National Board of Directors, Samuel K. Hoffman oversees design and production of Atlas, Thor, Jupiter and Redstone liquid rocket engines.

Q. *Mr. Hoffman, can you give us an indication of the measure of effort Rocketdyne is putting into liquid propellant engines?*

A. We employ about 10,000 people. Of these, roughly 4000 are in our Engineering Department.

In facilities, we have about 600,000 square feet of floor space in the San Fernando Valley, 130,000 of our Slauson facility in East Los Angeles and 220,000 in our plant in Neosho, Mo. Our test areas include the 1700-acre propulsion Field Laboratory in the Santa Susana mountains and a 200-acre complex in Neosho.

Our purchases are running at slightly better than $70 million a year and the weekly payroll is about $1,250,000.

Q. Mr. Hoffman, will you please outline the role of liquid propellants in the field of missiles today?

A. Liquids today are the predominant type of propulsion in large missiles where their unlimited thrust, relatively small size, precision cutoff, high specific impulse, variable thrust and gimballing ability are particularly suited.

Liquids are also being used in some small missiles where a need for one of their unique characteristics outweighs the simpler structure of solid propellant motors.

I think there is no question in anyone's mind that present liquid propellant engines are capable of putting us into the space flight business. Certainly, the refinement of our present power plants is making a large contribution toward that future. The question of when is largely one of money.

Another application for the liquids is in the field of manned aircraft where the characteristics of long duration operation, safety, repeated on-off operation, thrust control and re-use are vital.

Q. Is this the X-15 sort of thing you're talking about in manned rockets?

A. Yes, the X-15, glide or skip bombers, rocket boost takeoff for some future ramjet airliner maybe—any use where the rocket motors are recovered or brought back for re-use.

Q. The Cook rocket test sled used a Rocketdyne engine. Isn't this a good example of a re-usable engine?

A. Yes. The best information we have is that it made over 100 runs with only routine maintenance—no major replacements. And in 130-to-140 runs the only failures were a couple of valves.

Q. This is quite a testimonial on the re-usability of liquid rocket engines, isn't it?

A. Yes. When we delivered the engine, we predicted 300 runs before it would wear out, and it could well be a lot more than that.

Q. What about the cost of liquid propellant engines compared to solids?

A. For present one-shot applications, it depends largely on how the engine is to be used, which is cheaper. However, when the day comes that you can recover or desire to recover a missile powered by a rocket engine, the liquids will really come into their own. Then they'll be quite cheap. Like your automobile, you put fuel into it and run it; you make one trip and come back, fill it up with fuel again and then get on your way.

Q. Doesn't this seem to indicate that insofar as any possible potential commercial application of the chemical rocket propulsion is concerned, liquids are well in the lead?

A. I believe so, and I believe there'd be general agreement on that.

Q. Do you have any trouble turning a liquid rocket on and off?

A. When you say you have no trouble doing any of these things, it's a relative thing. The engines we work with today are sort of in the Model T stage. There are still troubles, but they are a lot different today than they were two years ago. And progress will be much faster because we have more engines to work with, more experience. Progress, insofar as reliability is concerned, is going along at a tremendous rate.

Q. Within the limits of security, for which missiles is Rocketdyne making engines?

A. We are building liquid propellant engines for the Convair *Atlas*, Douglas *Thor*, Army-Chrysler *Redstone*, Army *Jupiter* and until recently, the Air Force *Navaho*.

Q. Well, doesn't Rocketdyne supply the entire power package—engine, pumps, fuel tanks, valves, etc?

A. No. We supply the engine itself and its immediate supporting equipment. Somebody else supplies the tanks, lines leading to them, valves, etc.

Q. Does Rocketdyne have any licensing or exchange know-how agreements with any companies abroad?

A. We have a license agreement with Rolls-Royce. They have a license from us to build our engines.

Q. You are restricted by security on just what plans and specifications you can supply under such an agreement, aren't you?

A. Yes.

Q. What is the largest liquid propellant engine NAA has fired—in terms of straight thrust—in terms of specific impulse?

A. We are not in a position to give you the highest thrust or specific impulse figures that we have reached, but we can tell you we have produced an engine with the highest thrust rating that we know of to date—and by a considerable margin.

Q. Can you comment on the cost of liquid propellant motors?

A. Costs today, even in small quantities, are something on the order of one third of what they were when production first started. They may go down still more. Basically, cost is associated with quantity. If Ford were making 1000 cars a year instead of in the millions, we couldn't afford to buy one. And that's about the same situation

here. Quantities are so small that high production techniques are just not applicable.

Q. Is Rocketdyne doing any research and development on solid propellant rocket motors?

A. Yes, during the past five years we have engaged in several developmental projects and subsequent pilot production programs.

Q. Can you give us some estimate of the measure of improvement in specific impulse and mass ratio in liquid propellant engines by the use of additives?

A. The first thing I think we should do is define the term "additive". We will assume that an additive will constitute no more than 20 per cent to 30 per cent of the propellant into which it is placed. With this definition in mind, performance gains, in the order of 3 per cent to 5 per cent, may be realized through the use of additives in certain fuels and/or oxidizers. This gain in specific impulse performance would correspond roughly to 10 per cent in mass ratio for missiles of the intermediate and intercontinental ballistic type.

Q. What are some of the more promising additives?

A. The probable future trend in rocket fuels and oxidizers will be toward increased hydrogen content in fuels and increased fluorine content in oxidizers. On that basis, promising additives would include hydrazine and other compounds with concentrations of either of those two elements.

Q. What's the general consensus on the future role of fluorine, boranes, etc?

A. It is probable that the trend in oxidizers will be toward increased fluorine content. With boron, a great deal of experimental and analytical work faces us before we can be certain of the gains to be had.

Generally speaking, there are inherent problems in the future use of high-energy propellants, but we certainly can't rule them out on chemical grounds. The engineering problem of adapting them to reliable powerplants, or powerplants to the propellants, is not insurmountable.

Q. We understand that the temperature limitations of materials place an absolute limit on improvement of specific impulse of 40 per cent compared to current levels. Is there any known device by which this ceiling may be breached with liquid propellant motors?

A. The energy limit which has been quoted widely recently—and we refer to it as being a possible improvement of 50 per cent rather than the 40 per cent you mentioned—deals with molecular species and the energy derived from their normal chemical, or valence, bonds. The limit is one of propulsive energy rather than temperature. For instance, the combustion temperature of the highest specific impulse theoretically available—that of 373 theoretically possible through the combination of fluorine and hydrogen—burns with a temperature of about 5100°F. The second highest, in these theoretical tables, is specific impulse of 364 by oxygen and hydrogen, with combustion temperature even lower—that of 4500°. In contrast to this, the lower specific impulse of 316 from fluorine and hydrazine would develop combustion temperatures of nearly 8000°. The key to the limit of propulsive energy is not temperature but the best combination of high combustion temperature and low molecular weight of products.

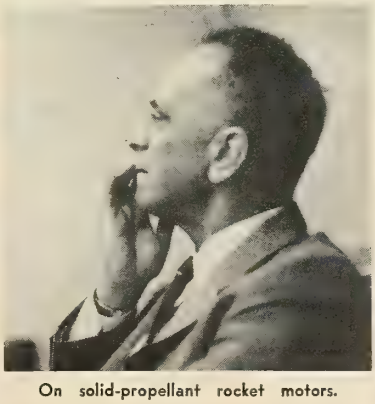
It is true, of course, that more energetic fuels and oxidizers, because of their weak bonds and relatively high vapor pressures, will be progressively less capable of handling the high thermal loads which will be impressed upon them in the regenerative cooling passages of future engines.

The ability of the engine materials to withstand the high combustion temperatures associated with the highest performance chemical propellants is not fundamental by limitation in liquid rocket engines since cooling methods are characteristic of this type.

If energy sources other than chemicals are employed, material temperature limitations are a major problem.

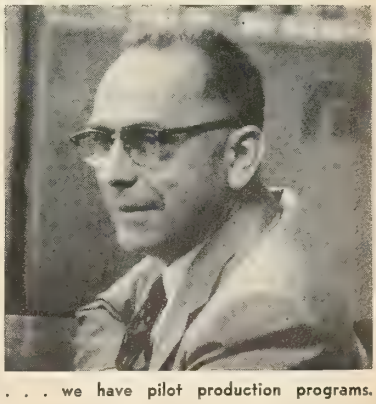
Q. Is any consideration being given to development of electromagnetic thrust chambers and nozzles—along the principles of the "pinch" effect that's being worked on for controlled thermo-nuclear rockets? Could this principle be successfully applied to chemical rockets and would it be worth while in terms of mass ratio (considering need for high wattage electric power source, etc.) for large, long-range space vehicles—or do other systems promise more efficiency?

A. It is conceivable that the principle of an electromagnetic thrust chamber based on the "pinch" effect could, someday in the future, be used for propulsive purposes in conjunction with a liquid propellant rocket. I wouldn't want to rule it out.



Other systems of electromagnetic motors are also possible. We, for instance, are working for the USAF on a feasibility study of an ion propulsion system using charged ions accelerated by high voltage electrodes to very high velocities.

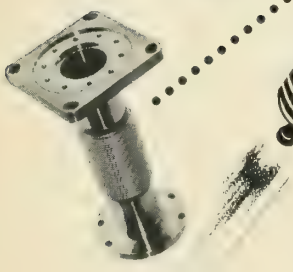
Q. What effect will the Navaho *cancellation have on Rocketdyne?*



A. This cancellation has had a relatively light effect on Rocketdyne, due to the fact that we are currently engaged in four other major rocket engine programs. Less than 500 persons, or roughly 5 per cent of our work force, were layed off as a direct result of the cancellation.★

We have a license with Rolls-Royce.

On solid-propellant rocket motors.



. . . we have pilot production programs.

From Gaslight to Satellite . . .

IN 1902 Flexonics Corporation began its experience in thin wall assemblies with the manufacture of "Kantleke" gas tubing, a product still manufactured and widely used on gas heaters.

IN 1957 IN THE HEART OF THE VANGUARD, a high performance flexible connector by Flexonics. Proofed at 1500 psi, it will go to work in the first stage of the earth satellite launching vehicle in the International Geophysical Year.

FLEXONICS
First in Fluid Flow

As a pioneer in the design and fabrication of light weight flexible metal connectors and ducting assemblies, Flexonics Corporation is proud to be the supplier of critical assemblies for many of the nation's most advanced aircraft, rockets and missiles.

The unmatched experience of Flexonics Corporation is available to help you in your problems of unusual design parameters, with applications incorporating the newest proven techniques and the most advanced thinking of the industry. Included among Flexonics products are metal, synthetic and Teflon* hose . . . flexible ducts . . . liquid oxygen lines . . . gimbals . . . pinned joints . . . high pressure ducting . . . thin wall tubing.

What's all this talk about EXOTIC PROPELLANTS?

By John F. Tormey
Chief, Research, Rocketdyne

IT IS ALMOST impossible to trace the time when the words exotic propellant first rose full-blown from the brow of a mesmerized rocket engineer. American rocketry has no historian and little recorded history after Goddard.

One recollection of the birth of exotic propellants goes back eleven years to 1946. It was customary then to assign an advanced study unit the task of creating, almost out of nothing, a list of all the liquid propellant fuels and oxidizers that could be purchased, found in handbooks, or conceived of by stretching molecular structural norms to their conceivable limits.

When the lists were prepared, well over half of the chemicals were known and available—alcohol, aniline, 70 per cent hydrogen-peroxide, ammonium nitrate, etc. The rest appeared to be new, unfamiliar compounds, products of uninhibited and sometimes inspired thinking. Such compounds as polyatomic oxygen (O_4), hydrogen molecules containing several atoms, and assorted halogen complexes were typical. Liquid ozone was a regular. Rather than list these things—of which he was generally a little self-conscious in 1946—along with the more regular and familiar chemicals, the rocket propellant researcher invariably made a second list which he titled "exotic," primarily because the testing fitted so well Webster's definition of exotic—"introduced from a foreign land." It was as if by labelling them exotic he had freed himself from any technical responsibility to defend or deliver them.

As is usually the case with the wrong word (exotic is no adjective for a chemical) it found immediate and ready acceptance, appearing in numerous reports.

Examples of exotic chemical compounds outside of rocketry abound everywhere. The application of silicon in the solar battery is a case where physical structure alone brought about something new and exotic. The successful formation of the first synthetic diamonds was an application of a chemical innovation and belief in principles in the face of difficulty.

The free radical particles produced under the Bureau of Standards' current program of fundamental research in that field have brought to light materials which might be defined as exotic both because of irregularity of formation, and also because of the magnitude of energy possible through the recombination of the freed particles. Tetraethyl lead, liquid helium, the boron hydrides, the classic freons, the bubble-forming isocyanates, now rather standard items of chemical commerce, were once exotic by definition.

And so it was also with many of the exotic propellants listed so lightheadly in 1946. They, too, were once exotic. The now familiar 90 per cent hydrogen peroxide was exotic in 1941, when 81.5 per cent produced in Germany was regarded as the highest concentration possible. Liquid flourine met the exotic definition until 1951. These and other exotic propellants are passing from a state of seemingly wondrous alchemy to practical chemical and rocket engineering.

But what of these exotic fuels? Are they above our ordinary considerations in every respect? Hardly. Rocket propulsion principle gives no reason to assume that because a material has been labelled exotic it need no longer obey the thermodynamic principles of rocket combustion and expansion in a nozzle. Like their less sensational brothers—oxygen, hydrogen, peroxide, jet fuel, alcohol and the rest of the other familiar liquid rocket propellants—the exotic species must square with the law which says that performance is a function of the square root of combustion temperature divided by the molecular weight of the products of the reaction. The theory says that the rocket propellants, exotic or otherwise, convert their internal energy into kinetic energy through the formation of energetic exhaust gases. The theory states that this energy will be derived primarily from the exchange of reactant bond energies for the bond energies of the reaction products. The rocket theory states that the molecular weight of the exhaust products is a factor in determining performance. Rocket theory also says that most rocket propellants will be formed from the first two periods of the periodic table.

Here, then are our ground rules. Regardless of the bizarre nature of the exotic propellant, regardless of any incredible property it may have, regardless of the persuasiveness of its advocates, when the exotic substance goes to work in a rocket combustion chamber, it has it no better nor worse than any other propellant because, exotic or not, each must follow the same physical laws, make generally

similar exhaust products, and be bounded by the same temperature and molecular weight conditions.

The exotic propellant has no special license to run up a high molecular weight in its exhaust products. It cannot generate exhaust products whose molecular weight is higher than 20 and it had better generate exhaust products whose molecular weight is less than 10, if it wants to keep its reputation.

On the matter of combustion chamber temperature, the exotic propellant must generate high temperatures at least equal to those generated by conventional propellants (5500°F) and yet its exhaust products must either resist dissociation or be of such chemical composition that a maximum of energy can be withdrawn from them prior to the atmosphere.

Each exotic propellant must be judged strictly on its merit. Now this is a pitifully obvious remark, but the exotic has been known to dim man's reason and blunt his judgment. It is well to keep in mind that there is no easy street in liquid rocket chemical propulsion. No matter how exotic the material may appear on paper, it still has two jobs to perform, to live in our environment and generate thrust on demand.

Exotic propellants can be thought of in the same way one considers exotic foods. To some, *escargots ala Francais* is a most exotic entree, particularly to the eye and the palate.

To stomach acids the once exotic escargots are now a collection of mixed polypeptides ready for energy release and tissue building.

During the past two years there has been a renewed interest in exotic propellants. Where does all this interest come from? Its primary source is faith, a faith which the majority of us have in the propellant chemists and the chemical industry to create rocket miracles. This faith can be touching (H_2O_4), futile (C_2H_2), or profitable (UIMH), as the case may be, both for the exotic propellant named and the chemical manufacturer in question.

Exotic propellants are probably our best path for substantial increase in power delivery. All manner of rocket power plants exist today, but if today's liquid rocket power plants are designed much beyond their present power level, we must go to higher performance propellants. The surest path for maximum increase will lie in the application of exotic propellants.

The same reasoning holds in the solid propellant field. If solid propellant power packages are to shake themselves loose from their present base at the impulse of 225 to 240, incorporation of new materials in the solid propellant matrix is probably the only solution to this problem.

Although there is no real and present reason to bring skepticism to bear on the field of exotic propellants, a few precautions are necessary. Any propellant can have hidden disadvantages which are not apparent to the over-enthusiastic. In the case of exotic plants, exotic furniture, exotic drinks and exotic places, what is irresistible at first glance proves later to be mundane and even dangerous.

Each new exotic rocket propellant, either solid or liquid, which appears on the scene should be probed cautiously by the conscientious. The exotic material must be subject to unimpeachable thermodynamic calculation to determine if it will deliver the promised power. It then should be subjected to unbiased laboratory tests to determine thermal stability, toxicity, resistance to decomposition, and the character of its combustion products.

It should be subjected to small scale motor firings to assay its general feasibility in real rocket applications. It should be thoroughly discussed with practical, down-to-earth, profit-motivated chemical firms. Can they make it? Do they want to make it? Do they have the plant to make it in? When could they make it? At what cost?

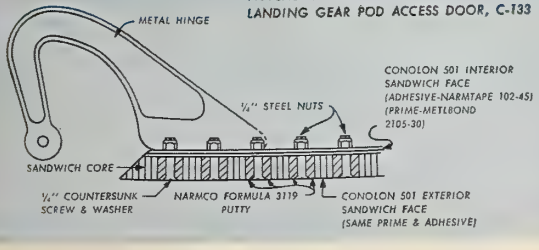
An exotic propellant must be shaken down before it can take its place with our other regular rocket propellants.★

DOING JOBS EVERY DAY THAT METALS ALONE CAN'T DO

Douglas C-133 Military Transport, the U. S. Air Force 100,000 pound payload leviathan of the skies

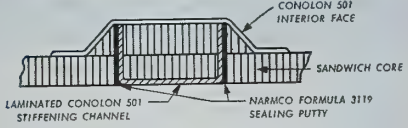
WHEN A SANDWICH NEEDS GRISTLE

You can depend upon versatile NARMCO FORMULA PUTTIES



In designing access doors for landing gear pods on the mammoth C-133 Military Transport, Douglas Aircraft Company's Long Beach Division engineers faced a familiar structures problem... how best to attach critical fixtures to a sandwich component at points of high stress concentration.

To anchor hinges to the severely contoured door required 40 through-sandwich attachments; the locking mechanism required 20 blind attachments... and, in each case, it was essential that stresses be dispersed into the surrounding core. A laminated fiberglass cross-stiffener also required a medium to disperse loads into the core.



The design solution? Easy-to-handle, room temperature setting Narmco Formula Putties. Hinges are secured by nut and bolt attachments through plugs cast of Narmco putty which, in shear tests, *outlasted the sandwich structure itself!* Locking mechanisms are secured by Shur-Loks anchored in Narmco Formula Putty and cross-stiffeners are securely attached to the core with these same high-performance putties. In fact, every through-sandwich access door attachment on the C-133 utilizes strong, dependable Narmco Formula Putties!

Facing a sandwich attachment problem? Let Narmco Formula Putties help point the way to an economical, performance-tested solution.

Individual Initiative in Research and Engineering

The Jet Propulsion Laboratory has brought together an outstanding staff of engineers of exceptional talent and ability. Working individually within the group these men now comprise a highly progressive and productive entity.

A recent survey of this staff indicated that the most important reason for their preference of JPL as a work center is the high degree of responsibility and freedom given the individual to pursue his own assignments. The intriguing nature of the work, challenging problems, professional association, fine residential location, pay scales and opportunities for career development were also important considerations.

This appreciation, from within, of the Laboratory's principle of recognizing ability and talent and allowing it to operate with freedom and confidence under its own initiative is a gratifying tribute in itself.

Working for the U.S. Army on a research and development contract with many ramifications, JPL has broad interests and constantly searches for new approaches to modern technical problems. This provides exceptional career opportunities for those qualified individuals who are interested.

FLUORINE . . . Tamed for Rockets

By Dr. H. R. Neumark and Dr. F. L. Holloway
General Chemical Division,
Allied Chemical and Dye Corp.

THE POTENTIALLY high performance characteristics of elemental fluorine as an oxidizer in rocket propulsion systems have generated a great deal of interest.

However, until the beginning of World War II elemental fluorine was prepared solely on a research scale. Then the development of atomic energy led to large scale production of fluorine for the manufacture of uranium hexafluoride.

Private industry recently entered the field of large scale fluorine production with the announcement by General Chemical Division, Allied Chemical & Dye Corp. of a contract with the Atomic Energy Commission to produce 5000 tons per year of uranium hexafluoride. This will require production facilities for about 1000 tons per year of elemental fluorine.

Further expansion is simply a function of demand. The plants would require no more lead time than other types of industrial facilities given similar priorities. Fluorine is no longer a laboratory curiosity. Today it is a commercial chemical which can be produced by industry in large tonnages just as liquid oxygen, hydrogen peroxide, nitric acid, or other oxidizers.

Until this year, the shipping regulations for fluorine limited its use. ICC regulations formerly restricted shipment of the gas to six pounds of fluorine in a 200-pound cylinder under 400 pounds pressure. The uneconomical weight ratio of 1 pound of gas to 33 pounds of container virtually ruled out shipment and use in large tonnage applications. Now, however, General Chemical's development and practical demonstration of an ICC licensed tank system, which permits bulk storage and shipment of liquid fluorine, has materially changed the picture.

The U.S., Canada and Mexico have ample reserves of fluorspar to take care of any emergency military requirement, in addition to an expanding civilian market for flourine-based products. To quote from the testimony of Mr. Josephson, Chief of Construction and Chemical Materials Branch of the U.S. Bureau of Mines, before the Senate Committee on Strategic Minerals, February, 1954:

"Fluorspar reserves containing 35% or more calcium fluoride would include nearly all the known deposits that are workable under present economic and technological conditions. Reserves of domestic ore containing more than 35% calcium fluoride are estimated by the U.S. Geological Survey to total 15,000,000 net tons, not considering development of latent reserves.

"If reserves of Mexico and Canada are added to those of U.S., the total ore containing 35% CaF_2 is estimated to be 23,000,000 N. T. An additional 500,000 N. T. are estimated for other known Western Hemisphere deposits on a like basis. U.S. reserves of material containing 15-35% CaF_2 are estimated to be 20,000,000 N. T."

This means about 12 million tons reserves equivalent to acid-grade spar are equivalent to 6 million tons of fluorine. An emergency need for 100 tons of fluorine per day over a period of two years equals 70,000 tons of fluorine, or only 1.15% of our total reserves.

Selected Physical Properties of Fluorine

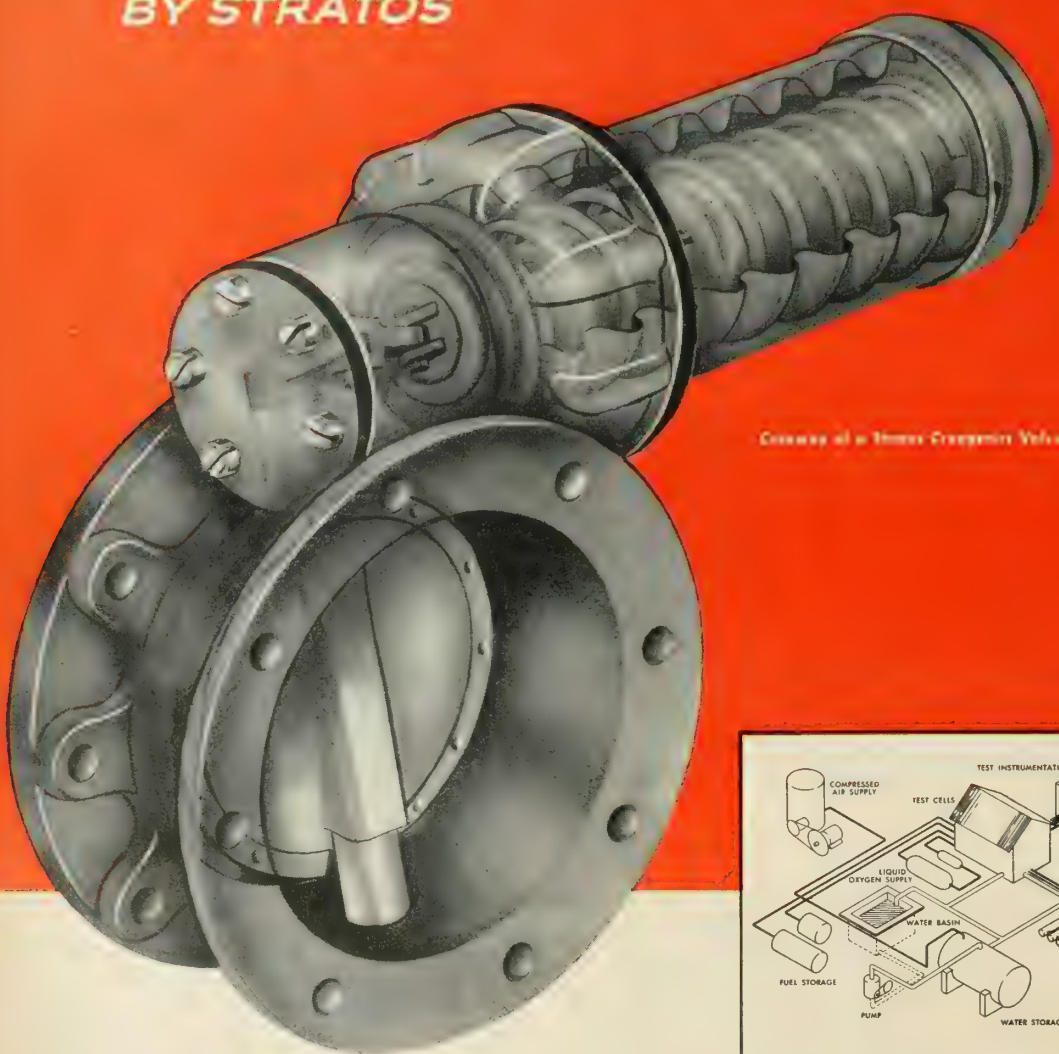
Chemical symbol	F_2
Molecular weight	38.00
Melting Point	−219.62°C. (−363.32°F)
Boiling Point	−188.14°C. (−306.55°F)
Heat of Vaporization at normal b.p.	1564 ± 3 cal/mol
Vapor Pressure Range: Melting point − 53.54°K to 90°K	$\text{Log } P = 7.08718 - \frac{357.258}{T} - \frac{1.3155 \times 10^{10}}{T^5}$ P= mm of Hg, T = °K
Entropy of Vaporization at boiling point and 1 atm	18.38 cal/mol °C
Critical Temperature	−129°C
Critical Pressure	55 atm
Liquid Density (g/cc at 81.0°K)	1.539 − 0.002
Gas Density (0°C and 760mm)	1.696g/l
Viscosity of Liquid (80.9°K)	2.75 centipoises
Viscosity of Vapor (°C and 1 atm)	218 micropoises
Thermal Conductivity (gas, 0°C and 1 atm)	5.92×10^{-5} cal/cm degree sec
Surface Tension (liq. at 81.0°K)	14.6 dynes/cm

Chemical Properties

Fluorine is the most powerful oxidizing agent known, reacting with practically all organic and inorganic substances. The heats of reaction are always high and most reactions take place with ignition.

The few exceptions are the inert gases, metal fluorides in their highest valence state, and highly-fluorinated organic compounds such as Teflon, Genetron* Plastic H-L, or Kel-F. Even the latter may ignite in a fluorine atmosphere if contaminated with a combustible material or if subjected to high flow velocities of fluorine.

The reaction of fluorine with most metals of construction is slow at room temperature and often results in the formation of a metal fluoride film on the surface of the metal. The characteristics and adherence of this metal fluoride film determines the resistance of the metal to fluorine.



Fluorine reacts with water, forming a mixture containing principally oxygen and hydrogen fluoride plus small amounts of ozone, hydrogen peroxide and oxygen fluoride. Fluorides exhibit abnormal solubilities and high complexing power and, of all the halogens, the fluoride ion has the highest heat of hydration.

Fluorine and oxygen, gaseous or liquid, are miscible in all proportions, with no reaction taking place between

CRYOGENICS VALVES AND PUMPS

BY STRATOS

Cutaway of a Stratos Cryogenic Valve

Schematic of the new Cryogenics Test Facility at Stratos Western Branch

With the facilities and experience to meet the growing requirements of cryogenics, Stratos is at work on a number of interesting projects in the low temperature field. Besides a basic background in the aircraft accessories field, Stratos engineering department includes specialists in cryogenics—men who have broad experience with gases at very low temperatures and with liquefied gases.

Among the cryogenic facilities at Stratos is a test installation recently completed at the Western Branch plant Manhattan Beach, Calif. This facility can test valves up to 12" diameter and achieve flow rates above 11,000 gpm.

Inquiries on valves, pumps, controls and systems are invited.

them either at ordinary or very low temperatures.

Materials for Handling Gaseous and Liquid Fluorine

Most common metals and alloys such as nickel monel, steel, stainless steel, brass, copper, aluminum and magnesium are quite satisfactory for handling fluorine at room temperature. At elevated temperatures, the use of nickel and its alloys and stainless steel is preferable. Monel proves to be the most satisfactory metal for all-around applications at low and high temperatures.

Safe Handling of Fluorine

Fluorine can be handled without undue hazards if proper precautions are taken. In order to minimize the risks involved, the following measures should be observed:

1) In handling fluorine under pressure, remote-controlled valves should be used, preferably those operated by manually actuated extension handles passing through suitable barricades.

2) Double valving should be employed in all cases where large quantities of fluorine are being handled such as with manifold cylinders or liquid fluorine tanks. Double valving is also recommended for pressure reduction of high pressure fluorine cylinders.

3) Any equipment to be used for fluorine service should first be thoroughly cleaned, degreased and dried, then treated with fluorine gas so that any impurities may be reacted without the simultaneous ignition of the equipment.

4) Clean Neoprene gloves must be worn when handling equipment containing or contaminated with fluorine. This precaution not only affords protection against fluorine but also against hydrofluoric acid which may be formed by escaping fluorine reacting with moisture in the air. Neoprene coats and boots may be worn to afford overall body protection for short intervals of contact with low-pressure fluorine or splashes of liquid fluorine. All such protective clothing should be designed and used, however, in such a way that it can be shed easily and quickly.

5) Safety glasses should be worn at all times. Metal frames are preferable to plastic which are a fire hazard. Face shields should be equipped with clear Kel-F or Genetron HI Plastic.

In addition to these special safety measures important for the safe handling of fluorine, common sense safety precautions necessary for the handling of any toxic or reactive material should be followed.

Barricade, Remote Control Systems

Barricade systems will vary widely depending on the buildings available. In general, the function of the barricade wall is to dissipate and prevent the breakthrough of any flame and/or flow of molten metal which could issue from any part of a system containing fluorine under pressure. Quarter-inch steel plate, brick or concrete walls are adequate for cylinder amounts of fluorine (nominally six pounds).

Remote control can be achieved by a wide variety of conventional devices. A common means of opening and closing cylinders is through a right-angled transmission of torque along supported rods by means of a beveled gear arrangement. Devices using universal joints can frequently be used to advantage. Needle valves can usually be positioned so that single straight rod manipulators can be used.

Materials for Fluorine Service

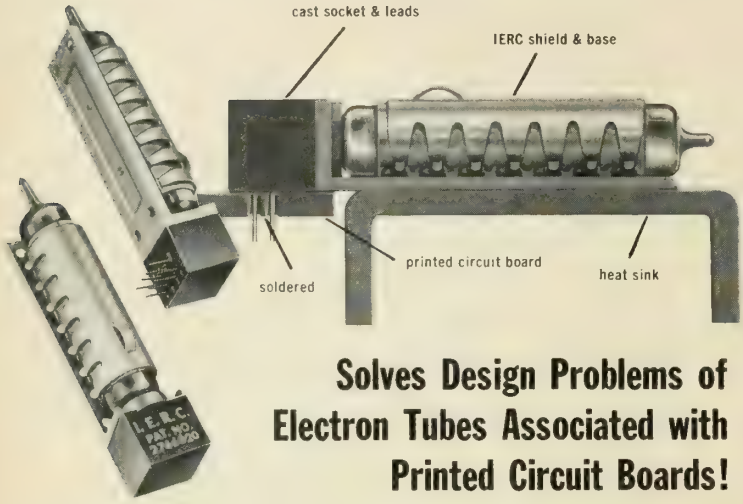
OXYGEN FLUORIDE—OF_2

Molecular Weight	54
Boiling Point	−144.8°C
Critical Temp.	−55.6°C
Liq. Dens. (g/cc at B. P.)	1.496

These compounds, like fluorine itself, are thermodynamically stable and exhibit an indefinitely long storage life.

Decontamination Procedures

Any equipment that has contained fluorine must be thoroughly purged with a dry inert gas such as nitrogen and evacuated prior to opening or refilling unless the system is used exclusively for fluorine service. A soda lime tower followed by a drier should be included in the vacuum line to remove trace amounts of fluorine in order to protect the vacuum pump.

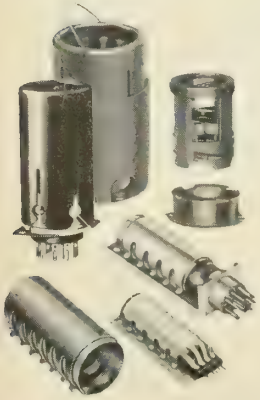


If large quantities of fluorine are to be purged, the disposal system should include a fluorine-hydrocarbon-air burner, scrubber and stack to prevent any exit hazards.

Liquid fluorine spillages should be neutralized with sodium bicarbonate. Dry chemical type fire extinguishers employing bicarbonate well-suited for this purpose. This material not only neutralizes the fluorine, but also assists in extinguishing any secondary fires caused by the reaction of fluorine with combustible material.

Packaging and Shipping

Gaseous fluorine is packaged and shipped in returnable ICC seamless high pressure cylinders #3AA-2400; these are 10 5/8" outside diameter and 55½" long without the valves. They are equipped with Chlorine Institute Valves having a ¾" male pipe thread cylinder connection and a left hand



IERC Heat-dissipating "plug-in" Tube Shields for Printed Circuits!

Solves Design Problems of Electron Tubes Associated with Printed Circuit Boards!

IERC's latest heat-dissipating tube shields for round button and flat press subminiature electron tubes solve design and performance problems of tubes associated with printed circuit boards. Standard socket and an Epoxy resin are integrally cast to the shield base. Socket leads extend from the Epoxy casting 90° to plane of base permitting direct plug-in to printed circuits for hand or dip-soldering of connections. Bulb temperatures are maintained to within 5°C of the heat sink temperature per watt of heat-dissipation when shields are attached, as suggested, to a heat sink of proper thickness for conduction or hollow duct types permitting air or liquid circulation. IERC's patented design provides maximum cooling, excellent tube retention, shock and vibration protection under severe conditions. Pertinent dimensions are to .1 inch grid layout.

Heat-dissipating electron tube shields for miniature, subminiature octal and power tubes

Circle No. 71 on Subscriber Service Card.

outlet thread with a nominal diameter of 1.030". The cylinder tare weight is approximately 195 lbs.; net weight is six lbs. The gas is shipped under 400 psig pressure.

Tonnage quantities of liquid fluorine are available in tank trucks, under a special ICC permit issued to General Chemical Division, Allied Chemical & Dye Corp., authorizing shipment of the product in cargo tanks designed in accordance with company specifications.

The tank system developed for storage and shipment of liquid fluorine is basically very simple. However, it required more than two years of research and development to perfect a system which did not involve any moving parts or mechanical refrigeration.

The tank system consists of three horizontal tanks, one inside the other. The innermost tank contains fluorine, which is kept in a liquid state by liquid nitrogen in the second tank. The space between the second and third tank serves as an insulating shield for the nitrogen. It is filled with pearlite or santocel and evacuated.

The workability of this design principle is based on the low boiling point of liquid nitrogen (—320°F) which is 14° below the boiling point of liquid fluorine (—306°F). This relatively small temperature difference permits keeping the fluorine liquid under a slight vacuum in an entirely loss-free system.

As long as there is liquid nitrogen in the second tank, there is no possibility of a pressure build-up in the fluorine tank. The insulation of the liquid nitrogen tank is so efficient that nitrogen losses are maintained at a very low level. No replacement of the coolant is required for a period of several weeks. The tank system is designed to be used either as stationary storage or as a bulk shipping container when mounted on a trailer transport chassis. It is also designed to be mounted on a railroad car.

Every conceivable safeguard has been provided to assure safe filling, storage, transportation and discharge of the tank system. In order to prevent discharging liquid fluorine in the case of accidental rupture of a fluorine line, each entry into the product tank is made through the top.

Double valving is provided for both gas and liquid fluorine service in order to prevent leakage into or from the tank. The discharge of the liquid fluorine can be either carried out by standard practice of pressurizing the tank with helium or through a pressure build-up coil which would pass warm nitrogen through a vaporizing coil immersed in liquid fluorine. The helium pressure discharge method is considered simpler and considerably faster.

Liquid Rocket Engine Control

By Rudolf H. Reichel

Bell Aircraft Corp.

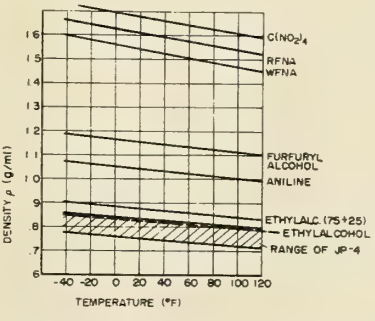
IN RECENT YEARS the development of large liquid rocket powerplants has followed a path similar to that of reciprocating engines, turbojets, and ramjets. Problems that were at first rather limited have increased in number and complexity leading to a more complicated engine configuration. The improvement of performance has led from simple adjustment and calibration methods to the application of control engineering philosophy. This trend has been primarily influenced by the following:

(1) Maintaining or varying the thrust vector and the combustion chamber pressure, according to a predetermined characteristic.
(2) Maintaining the propellant mixture ratio (oxidizer weight/-fuel weight).
(3) Maintaining the dynamic stability of the propellant feed system as well as the stability of the combustion process.
(4) Maintaining or varying major parameters according to a program such as combustion chamber pressure and mixture ratio for static firing test purposes.
(5) Compensation of transient or steady state errors resulting from manufacturing tolerances.
(6) Simplification of operation of the powerplant.

For airborne purposes, two basic parameters, mixture ratio and thrust can be automatically controlled.

Mixture Ratio Control

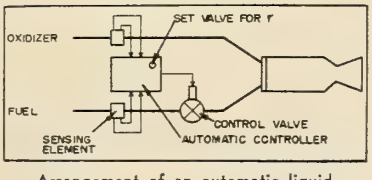
Automatic control of the mixture ratio is required in order to obtain a maximum cut-off velocity as the criterion for rocket performance. Its exact observance during the burning time will guarantee maintaining the optimum specific impulse and the complete emptying of both propellant tanks. With this a decrease of burning time as well as an increase of the total rocket mass at cut-off, is avoided.



The mixture ratio can be affected by several influences. Considering some different rocket propellant combinations as presented in Fig. 1, the density characteristics of fuels run approximately parallel to each other within a usual operational temperature range between —40°F and +120°F, as do the characteristics of oxidizers. However, the slopes of the two propellant groups are different. Therefore, a change in temperatures can lead to a noticeable deviation from the design point. Further alteration of the mixture ratio is possible by incorrect propellant weight flow rates due to incorrect pump characteristics or manufacturing tolerances of the various components. Finally, because of the effect of the missile acceleration on the propellant columns of different height and density, a deviation from the mixture ratio set point may also be expected.

A suitable control system which will consider these influences is represented in Fig. 2. The basic method is to measure oxidizer and fuel flow rates and to compare their ratio with the set value. Any deviation causes a control command by which the control valve will be operated until this deviation becomes a minimum. The control valve can be installed either in the oxidizer or the fuel side. For automatic control purposes, continuous or discontinuous control systems can be used.

For the *Viking* high altitude rocket which has a vertical trajectory during the burning time, an automatic mixture ratio control system was developed with the differential pressure measurement of the propellant columns in the tanks, Fig. 3.



In order to demonstrate the importance of the mixture ratio control with respect to rocket performance, the ballistic single-stage rocket corresponding to Table 1 may be taken for comparison purposes. The cut-off velocity value is based upon a vertical and drag free trajectory. It is obvious that design parameters can be maintained only

Figure 1

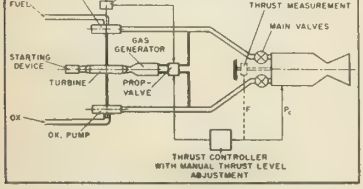
Figure 4

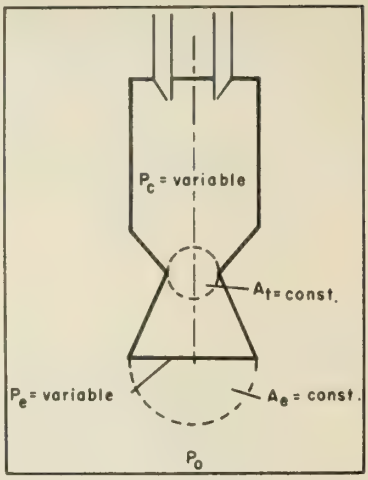
Loss of cut-off velocity and peak altitude, respectively, due to the inaccuracy of the mixture ratio using the propellant combination $C(NO_2)_4$/JP-4.



when the powerplant is accurately controlled. Fig. 4 shows the variation of the cut-off velocity v_c and the obtained peak altitude h, with deviation from the mixture ratio design value. The predominating influence for fuel rich combustion is easily explained by the high weight portion of the oxidizer. With respect to the cut-off velocity we find a diminution of about 5 per cent if the mixture ratio is only 2 per cent fuel rich which corresponds to a loss of 8 per cent of peak altitude.

In order to get a better idea of how missile acceleration affects the mixture ratio, the above-mentioned rocket can be taken as an example. In this case the predetermined mixture ratio varies from 4.52 to 4.9 under launching conditions, attaining 4.2 at cut-off. This corresponds to 9 per cent fuel lean and 7 per cent fuel rich, respectively. Such alterations of the mixture ratio cannot be accepted for large vehicles.

Thrust Control

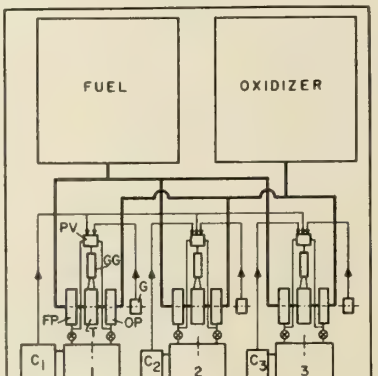


The importance of automatic thrust control depends on the required performance output characteristic of the rocket engine. In ballistic rockets, thrust will either be controlled to meet a specified acceleration requirement, or a constant thrust output will be maintained. However, the latter operating technique gives the best possible conversion of the propellants into rocket energy only if a drag free flight path

Figure 7

Thrust control system of a bi-propellant pump-fed powerplant with gas generator control for thrust level adjustment with the chamber pressure P_c as the control variable (dashed line: using thrust F as the control variable).

Figure 5

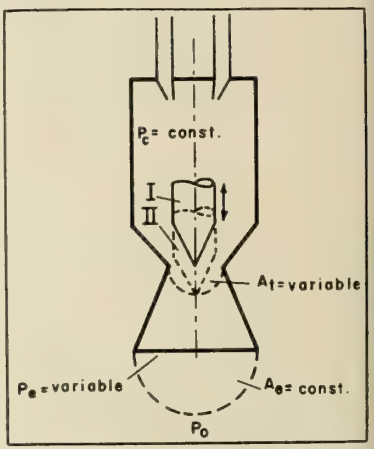


Parameters of a fixed expansion nozzle.

is assumed. Therefore, this operating restriction can be applied only for the upper stages of multiple-stage rockets. For all other cases the aerodynamic drag requires an optimum thrust programming in order to get highest possible cut-off velocity.

With respect to supersonic winged missile applications, the requirements of optimum thrust programing are similar. In many cases the propellant-wasting climbing phase will also be eliminated by launching from another ship. After release, the missile will then be propelled either by a quasi-

Figure 8



High thrust powerplant applying three combined rocket units. The master controller C_1 of unit I mixes the signals received from the other controllers C_2 and C_3 and compensates for the deviation according to the thrust set valve. Separate governor control loops are required to maintain stable conditions during starting transient. (PV = prop. valve; GG = gas generator; T = turbine; FP = fuel pump; OP = oxidizer pump; G = governor.)

constant thrust or the flight path will consist of a primary high thrust booth phase followed by an optimized lower thrust level cruising phase.

If a fixed expansion nozzle is used, Fig. 5, any off-design operation means a decrease of the specific impulse. For control purposes, the nozzle has to be designed so that with decreasing chamber pressure due to the throttling of the flow rate, shock conditions do not develop in the operating range. This occurs when the exit pressure becomes less than about 0.4 of the ambient pressure.

With a common injector, a decrease in injection differential pressure tends toward decreasing system stability even at a constant mixture ratio. This

Figure 6

Parameters of a variable expansion nozzle.

is due to the alteration of the injection flow pattern and the efficiency loss in propellant preparation for combustion. The use of several independently controlled injector groups may solve this.

With a variable throat area, Fig. 6, the operating conditions correspond to the fixed nozzle design at full thrust, i.e., when the throat plug is in position 1. For maximum throttling position 2, the limitation of the expansion nozzle area ratio is similarly affected by the critical pressure ratio due to the shock criterion. In order to control the engine, the throat plug position must be varied to maintain constant combustion chamber pressure with corresponding charge in the propellant flow rate.

The major design problem involved here is the high rate of heat transfer to this complex throat area control device. Similar to the fixed expansion nozzle design, heat transfer problems for the combustion chamber walls may also arise due to the decreasing propellant flow rate at lower thrust level.

The control procedure for a pres

Mixed Oxides are versatile, easy to handle

Propellant chemists and thermodynamic engineers seeking an oxidant uniquely suited to a wide range of rocket operating requirements find that Mixed Oxides offer these outstanding advantages:

Versatility — provides high specific impulse with many rocket fuels, including Triethyl-Trithiophosphate, Methyl Alcohol, 50% Ammonia and 50% Methyl Alcohol, 63% Triethylamine and 37% Orthotoluidine, Turpentine, Ammonia and Ethylene Oxides • **Freezing Point** — as low as —100°F, depending upon mixture • **Density** — compares favorably with other oxidants • **Easy Handling** — can be shipped, piped, stored in ordinary carbon steel • **High Stability** — non-corrosive, can be stored indefinitely in rockets maintained "at ready."

Mixed Oxides, containing 70 or 75% N_2O_4 and 25 or 30% NO, are economically available in large tonnages from Nitrogen Division's plant at Hopewell, Virginia, and for experimental purposes, in valved 125-lb. cylinders and 2000-lb. containers.

surized system using a fixed expansion nozzle motor can be performed by control valves arranged in the main propellant line. In case of more complex powerplants like those using a turbine-pump system, the propellant flow rate variation can also be achieved by automatic control of the turbine speed and the pump head, respectively, Fig. 7. In this case the combustion chamber pressure is the control variable. This method has this advantage: Any alteration of the mixture ratio will be limited due to the mutual dependance of both pump characteristics on speed. To compensate for the thrust increase due to the decreasing ambient pressure with altitude, the atmospheric pressure can be applied as an auxiliary control variable. This can be considered directly when the thrust force itself is used as a control variable (dashed line). For special requirements, it is possible to take the magnitude of missile acceleration as a control variable.

The automatic control system has to avoid any excess of turbine speed overshoot, say more than 5 per cent, and has to stabilize the engine operation at any dictated thrust level. It is obvious that these requirements need a close knowledge of the various parameters involved.

For high performance requirements multiple engine powerplants can be expected. Here, the thrust chambers will be arranged around a center line. Exact thrust control of any one chamber with respect to the others is required to avoid unsymmetrical thrust forces. In Fig. 8 such a high thrust engine unit applying three rocket motors is presented schematically. The extreme complexity of such a propulsion system can be seen by its block diagram, Fig. 9, disregarding the automatic control of the mixture ratio.

Mixture Ratio and Thrust Control

Considering a powerplant, Fig. 10, from the control engineering standpoint, several closed loops can be recognized which represent a dynamically complex system with correlative influences due to the cross-connections. Fig. 11. The thrust here is controlled by the chamber pressure, the mixture ratio by the fuel flow variation, and the gas generator system which is supposed to drive the gas turbine, by the turbine speed. Together with the feedback action of the chamber pressure, six closed loops result. The various pressure controllers, as usually arranged within the engine system, represent minor control loops which in case of instability act as disturbances on the major loops.

Combustion Stability Control

One of the major problems of rocket development is the dynamic stability of the combustion process even when an automatic control system is applied. Several investigators have pointed out that not only the configura-

SANBORN

CONSOLE RECORDING SYSTEMS

Up to eight problem variables can be recorded in inkless, permanent, rectangular-coordinate tracings—with Sanborn's improved six- and eight-channel 156-, 158-5490 Console Systems. Less than four feet high and about two feet in width and depth, these Systems are completely mobile and designed for maximum operating convenience. Controls and indicators on the sloping top panel include individual-channel attenuation, position, balance, sensitivity and stylus heat adjustments; switch for turning off B+ of output amplifiers; chart drive motor switch (can also be remotely controlled); code marker and/or one-second interval timer stylus switch. The Recorder unit, either six or eight channels, features paper loading from the top, and nine precisely controlled speeds from 0.25 to 100 mm/sec. Four dual-channel DC Driver Amplifiers of current feedback design are housed below the Recorder, and are mounted on a chassis which may be withdrawn for inspection.

Electrical specifications of the Console Recording Systems include a basic sensitivity of either .01 volt/chart division (5490 types) or 0.1 volt/chart division (5495 types); linearity of 1%; drift less than 1/2 chart division/hour (5490), less than 1/20 chart division/hour (5495); flat frequency response to 20 cps, down 3 db at 60 cps for all amplitudes to 5 cm peak; either single-ended or push-pull input signals of 5 meg. impedance (each input lead to ground).

A useful companion instrument is the new Sanborn Model 183 Programmer, designed to provide a connecting link between an analog computer and the Console Recording System. Shown mounted at the top rear of the Console, the Programmer operates the Console in the following automatic sequence: turns recorder drive on—feeds calibration signals to all channels—reads initial DC levels of computer—closes contacts to start computer problem—records computer output for a preset chart length—turns off recorder drive and resets itself for another cycle.

Further technical data, prices and delivery information—on the 5490/5495 Console Recording Systems and two- to eight-channel 5475/5480 Systems are available on request from your Sanborn Sales-Engineering Representative or the Industrial Division in Waltham.

tion of the combustion chamber and the injector, the chemical and physical properties of the propellants, but also the effect of dead time and non-linearity within the process, the stiffness of the structure including propellant tanks and lines, the propellant compressibility and aerodynamic forces, represent a complex system affecting the combustion stability.

Up to the present, the low and high frequency combustion instability problem must be handled more or less in an empirical manner although there are several theoretical papers which propose methods for the automatic control of low-frequency combustion instability. These control methods are not yet of any practical use.

Automatic Control Methods for Static Firing Test Purposes

It is an essential task of the static firing test to check design parameters and to examine propellant combinations. Common methods to determine the plot of specific impulse I_{sp} vs. mixture ratio step by step within a test series using manual control procedure, include some difficulties, especially when optimum conditions (e.g., constant chamber pressure) should be maintained. By application of automatic control methods, the function I_{sp}=f (mixture ratio) can be determined within only one run. This method results in saving of time and propellant expense, and improves the accuracy especially when oxidizers with a corrosive effect are used.

Using an automatically controlled arrangement according to Fig. 12, the following problems can be solved:

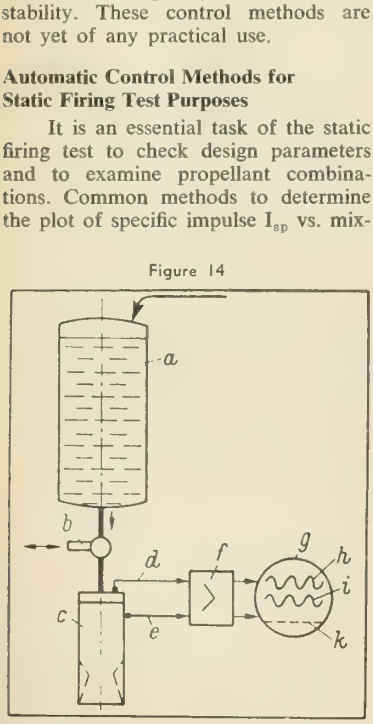
(1) I_{sp} vs. mixture ratio with the chamber pressure as the parameter, Fig. 13, solid lines.

(2) I_{sp} vs. combustion chamber pressure with the mixture ratio as the parameter, Fig. 13, dashed lines.

(3) Combustion chamber pressure and mixture ratio are held constant. This method corresponds to an acceptance test.

The last step would be to evaluate the test values by means of computers and to record the results even as the test run is being carried out. Besides the usual data such as tank pressures, thrust, propellant flow rates, and combustion chamber pressure, other values can then also be evaluated immediately after the run. To perform all required calculations computers are needed as plotted by dashed lines, Fig. 12.

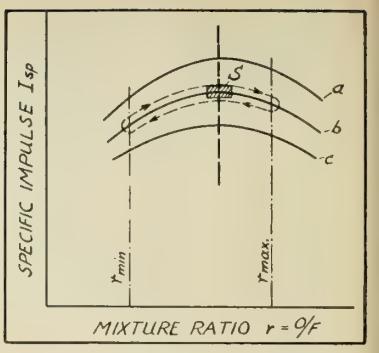
The Experimental Investigation of The Dynamic Stability



Theoretical papers try to represent the dynamic system, e.g., Figs. 10 and 11, by means of linear differential equations of the closed-loop or by the transfer function. However, for practical purposes there are limitations since the theoretical representation of the dynamic system and therefore the information on coefficients and disturbances, is hard to realize at the design stage.

Besides the experimental dynamic stability investigation of pressure regulators, turbine-RPM-governors, or any other control arrangements known in common control engineering, the investigation of the complete propulsion system is of a special interest. To consider a simple example of overall stability, a mono-propellant pressurized system is represented in Fig. 14. The investigation has to be performed under actual conditions with installed combustion chamber, lines, values, propellant tank, etc. Because there is an "internal" feedback action here due to the combustion chamber pressure, it is not possible to get open-loop conditions for investigation purposes. The only possibility is to feed the propellant feed system or even the combustion chamber with a harmonic disturbance. As an example we can disturb the propellant flow rate by means of a piston pulser (input variable) and record the chamber pressure response (output variable) depending on the frequency, in order to get the stability margin. Unfortunately, up to the present time it is very difficult to measure flow rate fluctuations reliably. For that reason we only can measure the injection pressure and determine whether there is any critical amplitude ratio (chamber pressure injection pressure ratio) within the required operating range.

In the case of a bi-propellant rocket, this method has to be applied accordingly, however, the harmonic disturbances are to feed in such a way that any alteration of the mixture ratio will not influence the overall stability.



As another example a thrust and mixture ratio control is considered. The dynamic overall stability can be determined when the thrust control loop as well as the mixture ratio control loop are to be cut and considered as open loops, points A and B, Fig. 15. The investigation then can be accomplished subsequently by feeding the loops with harmonic disturbances according to the operating conditions. ★

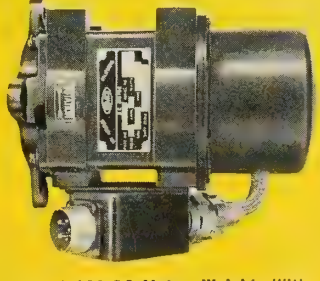
Because in missiles and jet aircraft everything has to work the first time

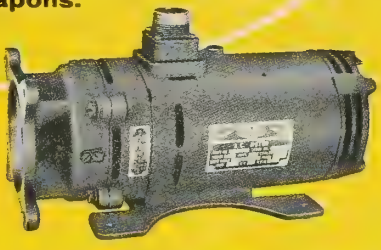
EEMCO AC and DC Motors

have been chosen for use in the majority of our latest aerial weapons.

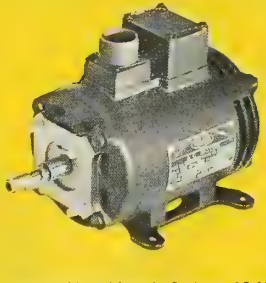
Type: C-1874 400 cycle 3 phase AC Motor and Clutch. **Weight:** 4.5 lbs. **Voltage:** 200 volts. **Output:** 650 watts. **Intermittent duty:** 12,000 rpm. **Meets Military Specification** MIL-M-7969A (ASG).



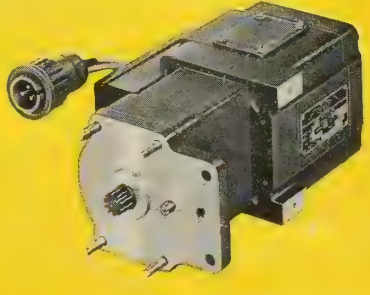
Type: D-751 DC Motor. **Weight:** 20 lbs. **Duty Cycle:** 5.2 hp at 2100 rpm (intermittent) on 26 volts DC; 3.5 hp at 2200 rpm (continuous) on 26 volts DC. **Meets Military Specification** MIL-M-8609.



Type: D-899 400 cycle 3 phase AC Motor. **Weight:** 11.25 lbs. **Volts:** 200 volts. **Load:** 2.75 hp continuous output. **RPM:** 3140 rpm output at gear box. **Power factor:** 83%. **Overall efficiency:** 76% for entire unit. **Meets Military Specification** MIL-M-7969A (ASG).



Over the years the precision, ruggedness and reliability of EEMCO products has been proven time and time again. The consistent, exceptional performance of these low-weight, high-output motors, a few of which are illustrated, has earned EEMCO industry-wide recognition. In this highly specialized field, where perfection is imperative, the widespread use of EEMCO motors and of EEMCO's equally reliable actuators is eloquent testimony.



Type: D-932 DC Motor. **Weight:** With radio noise filter—13 lbs., without same—12.4 lbs. **Terminal voltage:** 27.5 DC plus or minus 1.5 volts. **Load:** From .5 hp minimum to 2.6 hp maximum. **Speed:** Continuous at 12,000 rpm, plus or minus .005%. **Speed Control:** By frequency regulator supplying control field. **Meets Military Specification** MIL-M-8609 (ASG).

Type: D-638 400 cycle AC Motor. **Weight:** 17.5 lbs. **Voltage:** 200 AC, 20 amps at 6.5 hp. **Duty cycle:** 3.0 seconds at 6.5 hp, 15.0 seconds at 1.5 hp. **Maximum capacity:** 6.5 hp. **Continuous rating:** 5 hp at 2300 rpm, 15.8 amps, 200 volts. **Meets Military Spec.** MIL-M-7969A (ASG).

Type: D-800 400 cycle 3 phase AC Motor. **Weight:** 8.75 lbs. **Voltage:** 208 volts. **Horsepower:** 2.5 hp. **Continuous Duty:** 11,300 rpm; Equipped with thermal protector. **Meets Military Specification** MIL-M-7969A (ASG).

Type: D-927 DC Motor. **Weight:** 7.25 lbs. with 2-circuit noise filter for ungrounded systems. **Weight of filter:** 1 lb. **Terminal voltage:** 27 volts, 18 amps. **Load:** 0.5 hp. **Speed:** Continuous at 9900 rpm. **Meets Military Specification** MIL-8609.

Liquid Propellants for Manned Rocket Aircraft

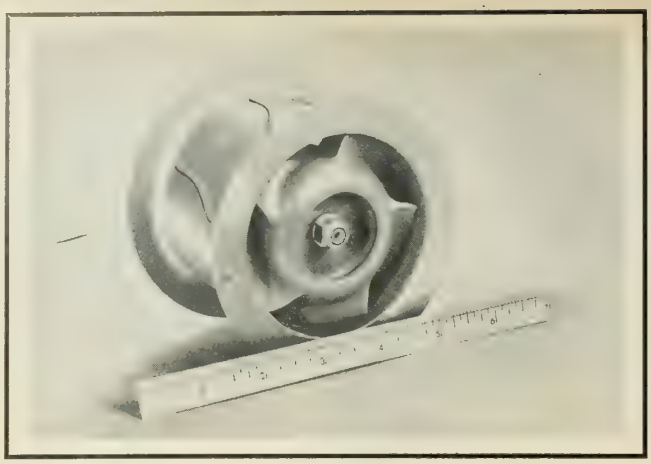
By William Mitchell
Reaction Motors Inc.

THERE IS A MILITARY NEED for manned rockets. Guidance lone may never measure up to the job f bringing in the shot on a pinpointed rget. At 150 lbs. a pilot represents rtain guidance functions that all the ectronic gear in the world couldn't uplicate. The pilot could act as ver- ier guidance to rain a whole fleet of her guided missiles on particularly oscure targets.

There is also the most exciting le of all, the passenger and cargo rrying rocket. It does not seem likely at a chemical rocket will ever propel an over interplanetary distances, nor en to the moon. That seems to be a b for the nuclear rocket.

North American has announced eir forthcoming X-15 with speeds omised in excess of those achieved to- ay. The propellants for the X-15 are announced but the others employ quid oxygen and ethyl alcohol. This mbination has done yeoman service the early missiles such as the V-2 d the *Viking*. While LOX and ethyl cohol fulfill today's needs, they will not do for tomorrow's job.

The manned rocket of the future will fall into one of the three classes already mentioned: the military rocket, the commercial rocket, the research rocket.



Propellant Requirements

The propellant requirements for each of these will in some ways vary from each other and from guided missiles. In most qualities the requirements of manned and unmanned rockets will be the same. The major difference between a manned and unmanned rocket is the need to return the pilot. This means some form of airfoil device to permit a glide return which results in a drag increase for a manned rocket greater than that of an equivalent impulse guided rocket.

The pilot must be protected from aerodynamic heating, so an additional cooling problem is impressed on the manned rocket. In addition, the pilot cannot withstand the same accelerations that can be tolerated by instruments, airframe and warhead. He must have oxygen, be protected from toxic leaks, and some sort of atmospheric pressure must be supplied. The hardware weight in a manned rocket will tend to be higher than is necessary for a guided rocket.

On the plus side, however, the manned rocket will require little or no guidance, although the pilot may depend to a large degree on data and instructions from electronic gear. The pilot is a reliability promoter and can correct some failures if they occur. In general, his ship should be less complicated in system concept than a guided missile.

For any rocket, manned or guided, high boiling point and low vapor pressure are desirable propellant characteristics: the propellant can act as a heat sink without boiling or requiring very high propellant pressures to remain liquid. Liquid temperatures can easily approach 300°F in supersonic dashes as a result of aerodynamic heating. On top of this—the regenerative cooling requirement of heat flux in excess of 10 BTU/sec-ft^2

— °F —the temperature requirements of the propellants can easily be raised to 500°F. It is a natural desire on the part of the designer to reject to the propellants the heat liberated in cooling the passenger of the manned rocket. So still another heat load is added to the propellants.

The ideal property of high boiling point is even more desirable for the manned rocket than for the guided missile. In all of today's manned rockets the liquid oxygen oxidizer is a totally worthless propellant in view of the high boiling point requirement. The other half of the propellant team, ethyl alcohol, is more noted for its cooling properties and thermal stability than as an energetic fuel.

Low Freezing Point

Propellants that do not meet freezing point requirements can sometimes be rendered usable by the use of additives such as ammonium thiocyanate added to hydrazine or water to hydrogen peroxide. Usually, the use of an additive to improve one property, such as freezing point, will result in the deterioration of another desirable property. For example, while the freezing point of hydrogen peroxide can be improved by adding water, the resultant solution does not have the oxidizing power that neat peroxide enjoys. Mechanical aids can be used to overcome high freezing point such as heating blankets, blowing warm air around a propellant tank, or storage of propellants in heated areas. All of these add to the complexity of handling equipment.

The desirable property of low freezing point can be somewhat sacrificed by limiting launching operations to tailor-made installations or temperate climates. While this may be tolerated for research vehicles, it would hardly be a worth while sacrifice for fleets of military rockets and it would exact a severe logistic penalty for future commercial operations.

A low value of viscosity plus a flat viscosity vs temperature curve is desired. Low values of viscosity are necessary for the small, superspeed pumps that are being designed into missiles. Lacking temperature independence of viscosity, the rocketeer must then accept engine performance variations or else build in a complicated compensation system.

As in the case of freezing point, the designer of a manned rocket may accept a relaxation of this requirement because in the pilot he has a guidance computer that can readjust to compensate for temperature variation. The pilot may be able to adjust the trajectory or the rate of propellant flow

immediate first aid for EYE FACE BODY contamination

HAWS Eye and Face Wash Fountains and Drench Showers provide emergency relief in seconds, where seconds count! Handlers of toxic or corrosive propellents or other dangerous chemicals *must* have immediate first aid in case of contamination. HAWS Emergency Eye and Face Wash Fountains permit instant washing of affected areas with controlled streams of water—spanning the danger period until medical aid arrives. HAWS Drench Shower sends a sudden torrent of water to rid body or clothes of contaminating material, before permanent damage can result.

Strategically placed in danger areas, HAWS Emergency Facilities have simple fool-proof operation—hand valve, foot treadle or pull chain. Models are available with eye-wash fountains separately or in combination with face-wash and/or drench shower. For particular applications, models will be fabricated to specification.

HAWS Emergency Facilities now serve at numerous jet, missile and research installations. They serve both for emergency first-aid, and also as a routine precaution by which employees periodically rinse away foreign materials.

to maintain the planned mission for the vehicle.

The missile designer is constantly faced with a choice between high density or high impulse, rarely does he enjoy the advantage of both. Fuels usually run to densities less than 1.0 gm/cc—more often than not around 0.8 gm/cc. Oxidizers are heavier, running from around 1.14 gm/cc for liquid oxygen to 1.55 gm/cc for red fuming nitric acid and fluorine. Practically all rocket propellant systems use more pounds of oxidizer than pounds of fuel, and this is a distinct advantage in lowering tankage weight.

In the past most of the rocket chemist's attention has been devoted to rocket fuels, but in the past few years there has been a switch to more research in oxidizers. Fuels still command the lion's share of propellant R&D. Oxidizers offer a promising field for research, since most oxidizer molecules are dense, and rocket engines always operate most efficiently on the fuel rich side. It is through oxidizer research that the present bulk densities of propellant systems can be raised from the prevailing range of 1.0-1.2 gm/cc to the 1.5 gm/cc range.

High density for the manned rocket is a must or else the rocket is forever chained to sub-space flight. The silhouette must be kept small so that the rocket can be launched from a mother vehicle. Ground-launched, manned rockets require a glide vehicle for the pilot's return. The added drag of the return vehicle must be compensated by high propellant density and a subsequent lowering of drag area through compact tankage.

Present-day manned rockets utilizing LOX and ethyl alcohol are in violation of the high density principle. These rockets are very limited in flight capacity.

Nontoxic Requirements

Aviation gasoline, jet fuel, and liquid oxygen must be considered toxic, or at least dangerous propellants, by the usual methods used to determine toxicity. Beryllium, now labeled dangerously toxic from its history in the fluorescence field, is practically ignored as a fuel atom.

Meanwhile boron is the subject of a great deal of experimentation, although beryllium has at least as bright a theoretical future. Such taboos can be overcome as indicated by the rise in liquid fluorine and liquid interhalogen research as rocket oxidizers. With materials research and handling techniques constantly lessening the danger of accidents, it is not unlikely that dangerously toxic materials will be tolerated for manned rockets of the future.

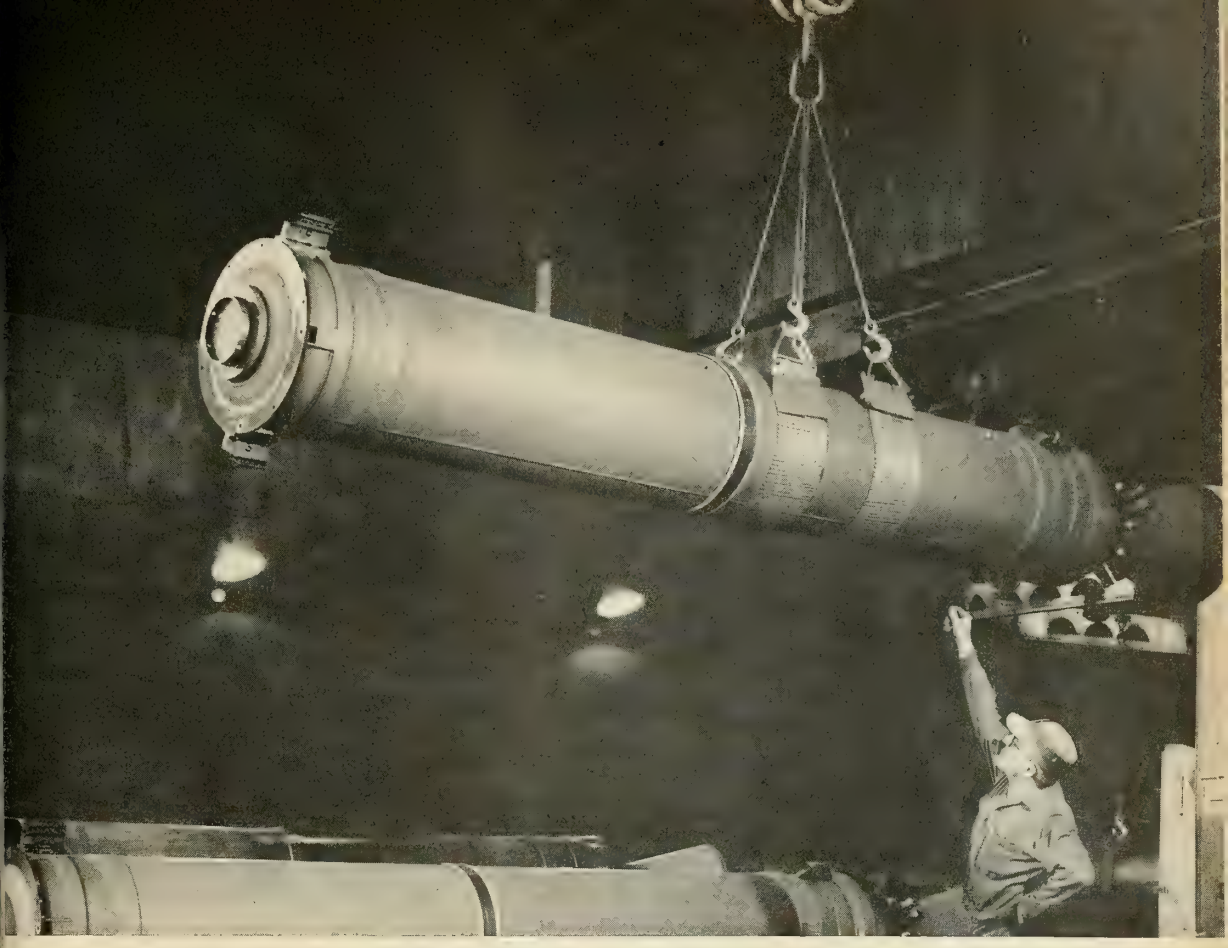
Toxic propellants can be controlled through adequate containment and toxic exhaust products can be vitiated by treatment or firing in remote places.

Noncorrosive Factor

There are no "ordinary" materials capable of containing some of today's corrosive propellants. Today's rocketeer talks of stainless, inconel, aluminum, silver, nickel, monel, teflon, Kel-f, fluorlub, etc. These are now "common" materials. The program leading to the synthesis of a new propellant quite often touches off an equally large program in the synthesis of a new alloy compatible with the propellant or its combustion products.

Liquids that can propagate explosions in the liquid phase are considered unsatisfactory for any kind of rocket, since involvement of the entire propellant supply in the tanks is possible.

The field of shock sensitivity is still far too much in the realm of clairvoyance. There are many propellants moderately labelled shock sensitive that await standardization and interpretation of tests. This is one facet of propellant chemistry that is receiving a great deal of attention today. The very nature of the molecular instability is an advantage when one considers the propellant from the viewpoint of wanting high specific impulse. A definition of tolerable limits is needed.



The requirements for a manned rocket are no different in this respect than for a guided rocket, unless, as in the case of corrosivity, a little extra is required.

Ease of Ignition

There is probably no area which has been more of a headache to the combustion chemist, the thrust chamber designer, and the test engineer than accomplishing safe, positive, repetitive starts and maintaining smooth combustion. Since it is impossible to predict combustion kinetics, propellants are evaluated and chambers are designed on equilibrium conditions and a number of ignorance factors commonly called "experience."

The size of the combustion chamber and the injection arrangement is usually finalized after hundreds of hot tests, some of which result in harder starts than the test chamber can stand. There are spark igniters, glow plugs, pyrotechnic squibs, hypergolic leads sequenced operations, injector face shutoff valves, splash plates, and other sundry rocket engine tricks to overcome our lack of knowledge of combustion kinetics and droplet burning. Since these problems are not likely to be solved soon, we must fall back on "experience."

A rocket industry innovation is

HONEST JOHN, complete except for propellant, warhead and fins, is built of steel by ALCO under prime contract.

STEEL MAKES A BIRD

ALCO's unparalleled experience in steel fabrication aids in producing missiles

For more than a century ALCO has been fabricating steel plate – first into locomotives, then also into heat exchangers, pipe, diesel engines; now into the strong and critical shapes of missiles. ALCO brings to this new problem the special competence that only an experienced steel-plate fabricator can offer.

A long history of defense production – both under prime contract and subcontract – is another ALCO asset. Just completed is a contract for M48A2 tanks, now in production is Army's Honest John, as well as Air Force Snark components. On another frontier, ALCO recently completed the Army Package Power Reactor on prime contract; leads in supplying nuclear components under subcontract.

Seven plants in five states, with a machine tool inventory of over $50 million, make ALCO defense products. For more information, including a new brochure, "What does it take to make a missile?," write Defense Products, Dept. ONM-2, P. O. Box 1065, Schenectady 1, N. Y.

the hypergolic pair, in which the fuel and oxidizer ignite on mutual liquid contact. Hydrazine and red fuming nitric acid (RFNA) are such a typical pair. Fluorine and nearly any fuel is another pair, while hydrogen peroxide can accomplish ignition with many fuels because the exothermic decomposition of the peroxide provides temperature as well as free oxygen.

The ignition delay of a hypergolic pair must be short enough (less than 50 milliseconds, preferably less than 20) so that propellant cannot accumulate in the chamber to create an explosion.

Good ignition and combustion is a must for manned rockets.

High Specific Impulse

This is the most important property of all, for it is in the bond energies of the molecule and in the resultant combustion product that the chemical energy is converted to kinetic energy. The parameter specific impulse is usually defined as the pounds of thrust per pound per second of propellant flow or $I_{sp} = F/W = \frac{\text{lb.}}{\text{lb. 1/sec.}} = \text{sec.}$

The propellants react in the chamber to produce heat and gaseous products. The products expand through a nozzle, converting part of their heat energy to kinetic energy, and are exhausted. The specific impulse of a rocket motor depends only on the nature of the propellant, the chamber pressure and the exhaust pressure. The only properties of a propellant that affect specific impulse are empirical formula and heat of formation.

There appears to be a limit of about 400 seconds to specific impulse for chemical rockets. It is unlikely that a manned rocket will ever achieve this since this high a value will probably require high heat of formation propellants which lowers sensitivity and thermal stability.

Specific impulse is a measure of impulse per unit weight. The term density impulse has been created to represent a measure of impulse per unit volume.

$$I_{sp} = \frac{\text{impulse}}{\text{unit weight}}$$

$$\text{bulk density} = \frac{\text{unit weight}}{\text{unit volume}}$$

Therefore,

$$(I_{sp})(\text{bulk density}) = \frac{\text{impulse}}{\text{unit volume}}$$

A high density impulse is desirable in reducing silhouette for manned rockets, but not at the expense of low specific impulse coupled to a high density propellant combination. The weight of the pilot plus the special hardware and glider requirements represent a fairly heavy payload and high value of specific impulse is a must if the rocket is to be propelled very far. Therefore, the manned rocket has the same requirements as the long-range, heavy payload guided missiles, namely high specific impulse. On top of this it has the further requirement of high density to trim silhouette, so that it will fit in the mother ship necessary for launch, or, barring that, will present a low drag area for ground launched vehicles.

High Thermal Stability

If any rocket motor is to survive for very long with combustion gas temperatures of 4000 to 10,000°F, it must be cooled, or else the burning time is restricted to seconds, not minutes. The heat is usually rejected to one or both of the propellants. In a manned rocket, the extra cooling required dictates a need for thermally stable propellants.

To be thermally stable, a propellant should not decompose exothermically, or become excessively shock sensitive as temperature increases. To maintain satisfactory cooling of the rocket chamber, the propellant must stay below the critical temperature, and remain a liquid in the cooling passages without resorting to extremely high fluid pressures.

High impulse fuel usually dictates materials that are inherently sensitive due to high heats of formation, and this basic sensitivity cannot be overcome by additives. A compromise must be made between performance and sensitivity. One such compromise is the case of unsymmetrical dimethylhydrazine (ULMH) over hydrazine. Another is liquid oxygen over liquid ozone.

The requirement of high thermal stability is more necessary for the manned rocket then the unmanned rocket; however, some degree of instability must be tolerated to gain performance. There is a great need for propellant research in producing thermally stable propellants that pack performance. If none are found, manned rockets will never be much more than a dangerous research tool.

The accompanying list and table gives an approximation of the qualities of some of today's propellants.

Jet Fuel and LOX

Combustion difficulties and hard starts are known. Specific impulse is better than average but not good. Bulk densities are low. Thermal stability of the jet fuel is good and may be used as a regenerative coolant. This propellant combination would support today's manned rockets, but density, specific impulse, and combination qualities are not up to tomorrow's needs. Availability and cost will always make this combination attractive.

Ammonia and LOX

These are readily available; cost only slightly greater than jet fuel and LOX. Specific impulse is about the same. The low density of ammonia is even more of a penalty than is jet fuel. While ammonia ignition is difficult, combustion is smooth and hard starts are rare. Ammonia is a good regenerative coolant and endothermic decomposition is an advantage. Satisfactory for current needs only.

Hydrogen Peroxide and Boron Fuel

Boron fuels have been announced as a future jet fuel. Therefore, it is a reasonable assumption that they will also be among future rocket fuels. Specific impulse is moderately high. Bulk densities are good. Cooling may be a problem, but both materials may be used as coolant. Costs are apt to be moderately high. No cryogenic fluids in this system.

RFNA and Amine

Acid density is very high. Hypergolic starts and smooth combustion prevail. Cost presently is fair, and may be relatively good in the future. Specific impulse is on the low side. Availability is good. Cooling can be achieved by both fuel and oxidizer. Low impulse will limit lifetime.

Hydrazine Liquid Fluorine

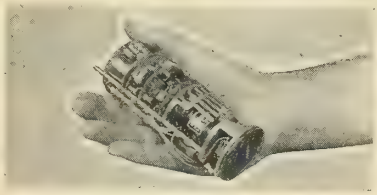
This is the ultimate in today's propellants for density and impulse. It employs hypergolic ignition. Very high flame temperatures and the uselessness of fluorine as a coolant plus the marginal thermal stability of hydrazine will probably mean a third fluid as a coolant. Cost will be high, and handling will be dangerous. This is one of the few materials that measure up to tomorrow's needs from the impulse and density view.

Liquid hydrogen appears to have no place in the manned rocket field due to extremely low density. Liquid ozone is far too unstable. Normal propyl nitrate and nitromethane lack impulse and present sensitivity problems for manned rockets. Ethylene oxide also lacks impulse, but may be used as a gas generator for turbopumps and auxiliary power units.

The field of propellant chemistry must produce the high specific impulse, high density and thermally stable materials that tomorrow's manned rockets need. If not, the answer must be sought in nuclear rockets or space particle rockets, or else man will have to be content with flying up to a few hundred thousand feet and then gliding back to earth.★

NOW FROM FORD INSTRUMENT ALL-SILICON-TRANSISTORIZED EXHAUST TEMPERATURE INDICATOR

Actual size of instrument face.



Check These Ten Superior Features

- Self-contained
- Instantaneous warm-up
- 2 sec. full scale response
- Wide environmental range
- No vacuum tubes used
- ±5°C accuracy
- Integral lighting
- Extreme compactness
- Integral power failure indicator
- No calibration required.

Developed for Navy BuAer For first time commercially available

Ford Instrument's Engine Exhaust Temperature Indicator was developed for the Navy Bureau of Aeronautics and is now available to other users. It is a self-contained unit which continuously displays temperature over a 200-1000°C range with ±5°C accuracy. Of extremely compact construction, it has less than one-third the volume and weight of comparable vacuum tube units. Silicon transistors are used throughout, enabling the ETI to withstand a wide range of ambient temperatures. Weight of the unit is only 16 oz.

High Applicability Coupled with precision measurement

Miniaturization provides a 2" diam. x 6" long self-contained unit. (Unit is shown with case removed.)

FICo's ETI is packaged in a single hermetically sealed case.

The FICo ETI is used for measuring exhaust temperature in turbo props, turbo jets—or in any other gas turbine within its range. It is a panel-mounted unit. Its high accuracy enables the pilot to closely observe engine temperature to ensure safe and efficient engine operation.

The fast response of the ETI makes it highly suitable for multiple thermocouple installations. It can be used as a monitoring unit with any number of chromel-alumel thermocouples in conjunction with a suitable switching device.

The ETI is highly applicable to laboratory flight test applications. In addition, with modification, it can be used in conjunction with airborne time-temperature recorders.

DIMAZINE . . .

comes of age as rocket fuel

By William G. Strunk
Westvaco-Chlor-Alkalai Div.
Food Machinery and Chemical Corp.

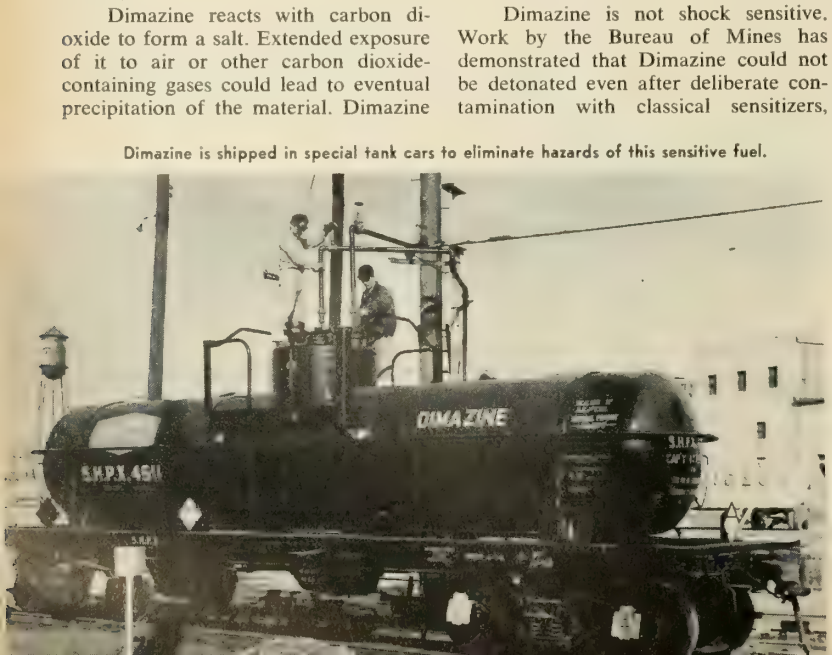
UNLIKE THE physically refined, naturally occurring hydrocarbon fuels, Dimazine is a specific synthetic chemical compound. Because it is a pure compound, produced under controlled conditions, its physical and chemical properties are constant. It is a clear, colorless, hygroscopic liquid with a rather sharp ammoniacal or fishy odor, generally characteristic of organic amines.

Its structural formula is $(CH_3)_2NNH_2$, and its molecular weight is 60. It has a specific gravity of 0.795 at 60°F/60°F and weighs about 6.64 pounds per gallon. It boils at 146°F and freezes at —71°F. The material is reasonably volatile, having a vapor pressure at 70°F of about 120 mm, or one-sixth atmosphere.

It is miscible in all proportions with water, ethanol and most petroleum fuels.

Dimazine has a flash point of 34°F and flammability limits in air from 2.5 to 95 per cent by volume. The autoignition temperature in air is 482°F.

Dimazine reacts with carbon dioxide to form a salt. Extended exposure of it to air or other carbon dioxide-containing gases could lead to eventual precipitation of the material. Dimazine reacts slowly with oxygen or oxygen-containing gases at ambient temperatures to form several products.



For flammability safety considerations, Dimazine is stored under nitrogen and under these conditions we have observed no formation of gums or other solids, even after sustained storage.

Range-forming work on high temperature stability has been carried out by heating small quantities of Dimazine in glass capillaries to successively higher temperatures. Essentially no decomposition was observed below the critical temperature of 482°F, or during thirty minutes at 550°F.

Some carbonization appeared at 700-800°F accompanied by a decrease in liquid volume upon cooling at ambient temperatures. Inclusion of nickel and stainless steel specimens in the capillary containers had no obvious effects. Further work investigating the high-temperature characteristics of Dimazine is under way. Dimazine mixtures have been used as regenerative coolants in rocket motors.

Dimazine is not shock sensitive. Work by the Bureau of Mines has demonstrated that Dimazine could not be detonated even after deliberate contamination with classical sensitizers, such as rust, copper and magnesium turnings and aluminum powder.

Dimazine is shipped in special tank cars to eliminate hazards of this sensitive fuel.

Materials of Construction

METALS. No known limitation exists on the use of nickel, Monel or Types 303, 304, 316, 321 and 347 stainless steel in contact with Dimazine. Aluminum and its alloys and magnesium (Dow metal 302) are good. Commercial Dimazine does not attack aluminum even with several per cent added water; however, some attack of aluminum has been observed by dilute aqueous solutions of Dimazine.

It should be noted that Dimazine typically contains about 0.1 per cent water. Easy Flow #45[1] silver solder appears satisfactory for use in brazing applications associated with Dimazine. Copper and high-copper alloys should be tested under proposed use conditions because we have observed corrosion of copper by refluxing Dimazine, although brass was essentially inert under these conditions.

Elastomers

Compatibility of Dimazine with a large number of non-metallic materials of construction has been checked. The best materials include Teflon[2], unplasticized Kel-F[3], polyethylene, Garlock gasket 900[4], Hydropol rubber[5], and graphite, but even less resistant elastomers are being used successfully in certain applications. Promising results are being obtained in a program developing fuel cells and bladders for Dimazine and Dimazine blends.

O-RINGS. Westvaco manufacturing facilities have used Garlock 90 gaskets with very good service. Polyethylene and Teflon have proven excellent as gaskets for shipping containers.

HOSE. The type of hose recommended will depend on the specific service intended. Flexible stainless steel and polyethylene hoses have been used for some applications. In view of the inertness of Teflon and unplasticized Kel-F, hoses properly fabricated of these materials would be serviceable

PUMPS AND PACKING. Conventional centrifugal pumps with graphite impregnated asbestos or braided Teflon packing is used in most instances. Chempumps[6] (sealless, centrifugal pumps) can also be recommended.

SEALANTS AND LUBRICANTS. Xpando[7] and Q-seal[8] have given satisfactory service as pipe dopes in production facilities. Because of Dimazine's excellent solvent properties, no completely satisfactory lubricant has been found. The current best recommendation is a mixture of Apiezon L[9] and graphite.

DRUMS. No unusual practices are indicated for the unloading and handling of sound sealed drums of Dimazine. If a leak results from damage of a drum in transit, the spilled material should be washed away with water before salvaging the remaining Dimazine.

It is recommended that drums of Dimazine be left sealed, just as received, pending need for transfer of their contents. Before unloading, the drums are conveniently emptied by either pump or gravity flow.

If the drum is to be emptied in a single operation, it can be vented during withdrawal by loosening or removing the plug from the opening not used for the liquid discharge. It is normally unnecessary either to maintain a nitrogen atmosphere or to dry the air that is drawn into the drum as the liquid contents flow out. It should be pointed out, however, that an explosive mixture may be present in the vapor space of the drum if air is allowed to displace the contents.

Neither oxidation nor moisture pick-up should be significant under these conditions. Before discarding, the empty drum should be flushed thoroughly with water to remove any small amount of Dimazine remaining. For drums being only partially emptied, the most conservative method requires that an atmosphere of inert gas be maintained within the vapor space as the contents are withdrawn.

Storage

There appear to be no critical limitations on storage environment. Mild steel tankage is satisfactory. Tests have shown Dimazine to be thermally stable at temperatures well above those normally encountered in the atmosphere. It freezes at a very low temperature.

From a practical viewpoint, storage should be maintained comportably below the boiling point of the material (146°F). A limit of 120°F as the peak temperature for sustained period is recommended. Large quantities should be stored in comparatively isolated areas, and oxidants such as nitric acid, hydrogen peroxide and halogens should be kept out of the immediate storage area.

Large quantities of Dimazine must be stored in isolated areas, and away from oxidants.

Studies suggest the use of horizontal cylindrical tanks, maintained under a slight pressure. Mild pressurization under an inert gas, rather than atmospheric breathing, is favored for reduction of Dimazine losses from periodic fills and withdrawals and from daily changes in ambient temperature.

Fire Hazards

As noted earlier, Dimazine is flammable. Open fires, sources of sparking etc., should be avoided and all equipment in which it is handled should be electrically grounded. Explosion-proof wiring, lighting and motors are indicated for areas in which it is to be handled.

A flammable mixture is present in the vapor space whenever Dimazine is handled under air. This is not unique to Dimazine, but is characteristic of a number of other chemicals and fuels frequently handled under air. Some of these materials that form flammable vapors with air at ambient temperatures are ethanol, methanol, acetone, ether and JP-4 jet fuel. As a safety consideration, the use of a nitrogen atmosphere is recommended over Dimazine.

Dimazine fires should be combatted with large volumes of water. This achieves both dilution and cooling effects. Liquid Dimazine burns smoothly and cleanly, and is readily extinguished on dilution with two or more volumes of water per volume of Dimazine. Much higher concentrations in water will support combustion, although flame intensity is progressively weakened as the Dimazine concentration of the solution is lowered.

Carbon dioxide and water fog are also effective in extinguishing Dimazine fires. Chemical foams are not recommended since Dimazine tends to deactivate the foam-forming surfactant and to destabilize the foam.

Toxicity

The acute toxicity characteristics of Dimazine are similar to those of hydrazine, and moderate care must be exercised in its handling. Westvaco has been producing substantial amounts of this chemical for several years, and has had no case of acute poisoning or evidence of chronic poisoning.

Our medical surveillance program

	MIL-F-25604 Specification	Typical Dimazine
Assay	98 wt. % minimum	99.2
Specific Gravity @ 25/4°C	0.783-0.786	0.7845
Distillation Range		
10% Temperature	143°F minimum	145°F
90% Temperature	148°F maximum	147°F
Melting Point	−70°F maximum	−73°F
Color (light transmittance)	90% minimum	96%
Water Content, wt. %	0.3% maximum	0.1%

includes a pre-exposure physical examination. Personnel exhibiting anemia or evidence of liver disease are not used on the operation. Hemoglobin and white blood cell counts are made at intervals of six weeks.

The safety precautions recommended for our plant operators are as follows: (1) If the odor of Dimazine is apparent, use a respirator equipped with an ammonia canister. (2) Wear splash-proof goggles and vinyl-coated gloves. If possibility of gross splashes exists, suitable splash-proof garments are recommended. (3) If splashes do occur, wash thoroughly with water and launder clothing and other protective equipment before re-use.

The most complete studies on the acute toxicity of Dimazine have been made at or under contract to the Army Chemical Center where they are currently studying the effects of chronic exposure.

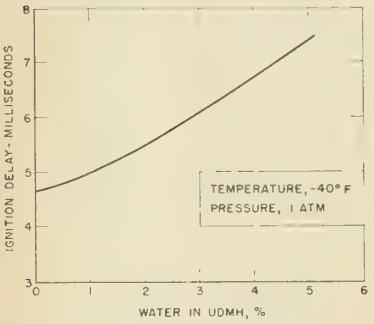
Propellant Applications

One of the outstanding propellant characteristics of Dimazine is its hypergolicity with fuming nitric acids and the very low ignition delay when used with this oxidizer. The ignition delay of this system is the shortest of any known —only a few milliseconds. It also has been satisfactorily used as a fuel with liquid oxygen. This system is not hypergolic but smooth burning results once ignition has been initiated.

The hypergolic character of Dimazine is utilized in a variety of ways. Propellant systems using only Dimazine and fuming nitric acid have been used very successfully. In other systems, a "lead slug" of Dimazine has been used to give reliable ignition to another nonhypergolic fuel system.

Dimazine has been used in blends with other fuels such as hydrocarbons to promote smooth burning. Rocket systems using Dimazine include the Army's *Nike Ajax*, the Air Force's *Rascal* and the Navy's *Vanguard*.

The results of a study of the hypergolicity of IDMH with IRFNA was reported by Potter and Byington at a meeting of the American Rocket Society in September, in 1956. They reported the following conclusions: (1) At atmospheric pressure, the ignition delay of UDMH in fuming nitric acid is very short, i.e., of the order of a few milliseconds. (2) Dilution of UDMH by up to 5 wt. per cent of water increases the ignition delay a small amount at −40°F. (3) Temperature, over a range of −65°F to 100°F, has little effect on the ignition delay of the UDMH-IRFNA system. Dilution with jet fuel (JP-4) increases the ignition delay only modestly at 70°F with a value of 30 milliseconds observed for a blend containing 40 wt. per cent UDMH. At −40°F the ignition delay of these blends rises rather sharply as the UDMH concentration is reduced.



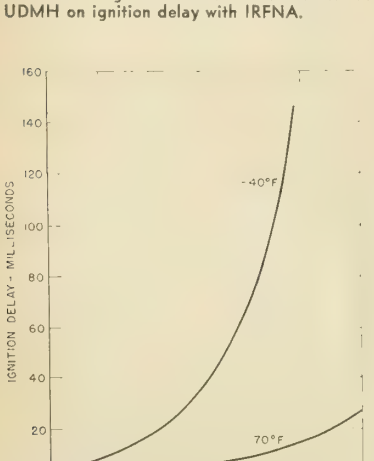


Table showing overall effect of water in UDMH on ignition delay with IRFNA.

Ignition delay of JP-4/UDMH mixtures with IRFNA showing delay in milliseconds.

Specifications and Analysis

A military specification, MIL-F-25604 (USAF), has been issued by WADC for unsym-dimethylhydrazine. We collaborated with WADC in development of this specification. Its key requirements are compared with typical Dimazine as shown in table.

Dimazine consistently complies with this specification and we see no economic penalty in maintaining this standard as opposed to turning out a material of lower quality.

We have proven the precision and accuracy of analytical methods for determining the properties listed in the above tabulation and will be pleased to supply copies of both the methods and the technical reports supporting them to those interested.

Supply Logistics

The basic raw materials for

To the ENGINEER of high ability

The most important engineering assignments are now being placed with companies which can point to superior accomplishments not only in research and development, but in production of the end items. Because of this, engineers interested in aircraft and missile components and systems will find outstanding opportunities at the Garrett Corporation. Our prime areas of operation include the following:

air-conditioning
pressurization
heat transfer and cryogenics
pneumatic valves and controls
system electronics, computers and flight instruments
gas turbine engines and turbine motors

The Garrett Corporation also has made important advances in prime engine development and in design of turbochargers and other industrial products.

Our engineers work on the very frontiers of present day scientific knowledge. We need your creative talents and offer you the opportunity to progress by making full use of your scientific ability. Positions are now open for mechanical engineers . . . mathematicians . . . specialists in engineering mechanics . . . electrical engineers . . . electronics engineers

For further information regarding opportunities in the Los Angeles Phoenix and New York areas write today, including a resume of your education and experience. Address Mr. G. D. Bradley

For control system applications...

the AiResearch time dwell electro-hydraulic servo valve

SPECIFICATIONS:

Weight	1.25 lb.
Electrical input	10 milli-amperes
Operating pressure	200 to 4000 psi
Rated flow	0.12 to 5 gpm
Fluid	OS45-1 (or) MIL-O-5606
Oil Temperature	−90°F to 400°F

New design results in high spool control forces with positive switching action

The AiResearch Time Dwell Servo Valve is a two stage switching type electro-hydraulic valve. It converts low level electronic signals into hydraulic energy which actuates mechanisms to steer or control missiles, aircraft, and ground control and similar equipment.

Weighing only 1¼ pounds, this AiResearch valve has the following characteristics:

Spool velocity rather than position is the control parameter.

Spool centering springs are not required.

Performance is maintained even with contaminated oil.

It is unaffected by accelerations to 50G in any direction.

It is insensitive to varying spool friction loads.

It has a wide temperature range of efficient operation.

In combination with a matched actuator, the Time Dwell Servo Valve gives true $1/s^2$ dynamic performance. This allows the servo systems engineer to achieve system response, resolution and stability previously unattainable.

• *Outstanding opportunities for qualified engineers*

UDMH are coal or natural gas, wate and air. Salt must also be included as source of chlorine if a modified Ras chig synthesis is used. Dimethylamine one of the building blocks for UDMH is made from methanol and ammoni and the second nitrogen in UDMH is also fundamentally derived from ammonia.

The equivalent of two moles o each of these chemicals appears i each mole of UDMH. When proceed ing through the nitroso route, hydroge is required to convert the nitroso t Dimazine. In the modified Raschi process, the ammonia is oxidized b chlorine. Chlorine and hydrogen ar cheap, readily available chemicals whic present no serious limitations to pro duction.

Less than one per cent of am monia-methanol capacity would be re quired to make 50-million pounds o UDMH annually. The processes in volved in the manufacture of UDMH are of a type that are readily adaptable to large volume production.

It has been Westvaco's policy t maintain capacity substantially in ex cess of demand. Engineering studie have been completed which will per mit prompt expansion of our facilitie if and when increased demand appears

The price of UDMH has bee steadily decreasing during the relative ly short time it has been in commerci production. Prior to 1954, the price o UDMH was about $15.00 to $30.0 per pound. In 1954 and 1956, this wa reduced to less than $4.00 and le than $3.00 per pound, respectivel Current price for tankcar quantities under $2.00 per pound.

Our engineering studies indica that a selling price of about $.50 p pound should be possible if large-scal sustained production is achieved. Th includes amortization of the investme and a modest profit.★

Inertial navigation: *the new art of guiding aircraft to a pinpoint . . . without stars, radar, or human help*

Aircraft will soon be flying so fast, so far, so high that present systems of navigation will be hopelessly obsolete. The need has long been urgent for a new method that doesn't depend on star-fixes or earth signals.

Ten years ago the AUTONETICS Division of North American Aviation began an all-out effort on the development of inertial navigation. For the great advantage of this method is that it is entirely self-contained, depending on nothing outside its own precise components . . . retaining its accuracy regardless of weather, magnetic storms, or jamming.

An inertial navigation system continuously determines an aircraft's position. Because it knows where it started from and how fast it is going, it always knows where it is. Everything is done automatically by an ingenious crew of accelerometers, gyroscopes, computers, servomechanisms.

Early pioneering and consistent follow-through by AUTONETICS has resulted in the greatest total accomplishment yet made in this new science. From the beginning, AUTONETICS has emphasized optimum reliability under actual field conditions.

Today AUTONETICS is producing in quantity the electro-mechanical systems it designs: inertial navigation systems, flight controls, armament controls, computers, and other complete automatic control systems for the military and industry.

GET EXACTLY 400 CYCLES PER SECOND WITH HOBART SYNCHRONOUS MOTOR GENERATORS

Model 1048—18.75 KVA

FEATURES:

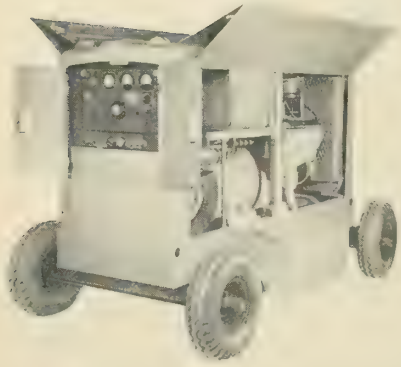
- Simplified Design
- Rugged Construction
- Dependable Performance
- Ease of Installation and Maintenance

USES:

- Aircraft Test Checkouts
- Flight Control Stations
- Communication and Navigation Systems
- Instrument and Maintenance Workshops

HOBART

. . . Foremost in Ground Support Power Supplies—Whether d.c. or a.c.!
Impressive in power and performance, Hobart Ground Power Support Units (d.c.) are known throughout the world as the chosen ground power unit in the commercial aviation field.



With the advent of jet aircraft, the merits of an a.c. electrical system is unquestionably the right choice, so the need for 400 cycle power is urgent. Research by Hobart indicates that units ranging from 3.75 KVA to 125 KVA are required. Design, development, and production of these new units are in progress at M.G.C. The Hobart d.c. line will, of course, take care of the limited supply of low voltage d.c. requirements on certain jet aircraft.

LOOK TO HOBART FOR . . .

- Induction motor-driven generators—direct drive
- Induction or synchronous motor-driven generators—belt drive
- Induction MotoDrive generators (380 to 420 cycles)—vari-speed drive
- Synchronous motor-driven generators—direct drive
- Engine-driven generators, self-propelled—gasoline or Diesel
- Trailer-mounted engine generators—gasoline or Diesel
- Truck-mounted engine generators—gasoline or Diesel

Model 3008-P
37.5 KVA

Checked to your specifications . . . Shipped to your schedules!

REGARDLESS OF COST . . .

you can't get a better frequency changer than Hobart because of these outstanding features:

- Complete instrumentation
- Magnetic type load contactor
- Voltage regulation is by a magnetic amplifier
- Overload relay opens the main contactor on overloads
- Over-voltage relay protects the aircraft in case of excessive voltage
- Transient voltage, output voltage modulation, response time, and wave shape are held to the closest possible limits

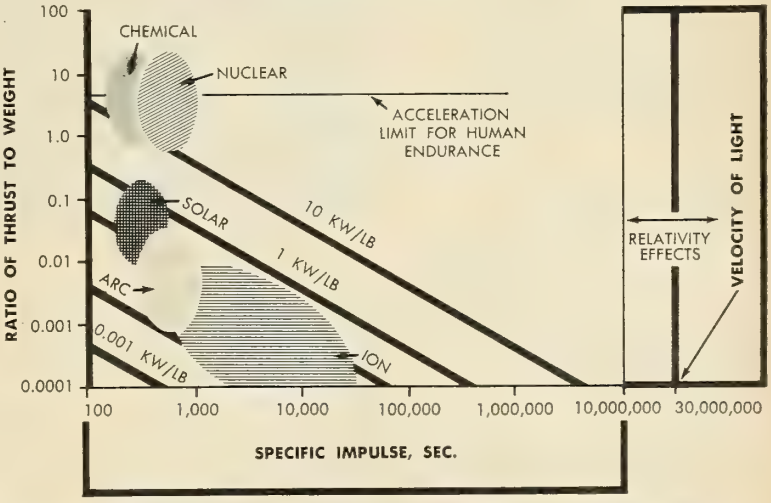
Propulsion Systems Evaluation

By George P. Sutton

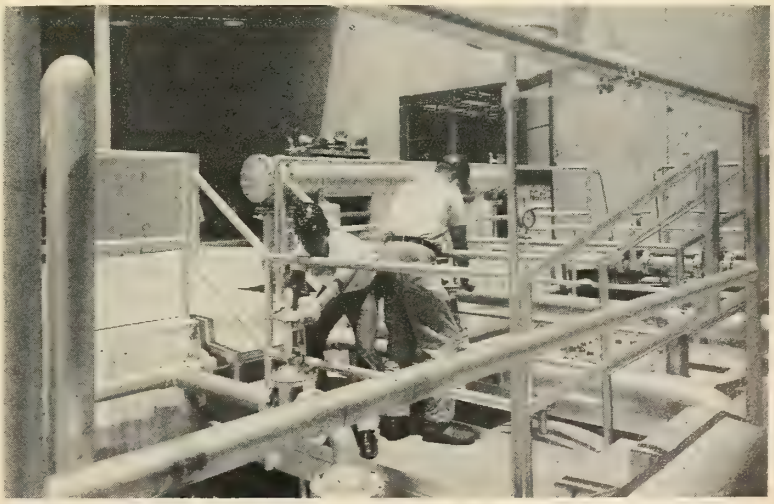
Chief, Preliminary Design Section
Rocketdyne

AN EVALUATION of future propulsion systems for space travel is, at best, highly speculative at this time. The technology of some of the more advanced propulsion systems needs considerable research and development. Some of them may prove to be fundamentally restrictive.



Analytical studies indicate that a number of propulsion devices, which will permit space travel, are theoretically possible. Those giving high performances will require a larger amount of energy expenditure per unit thrust. This implies that the problems of some of the more advanced propulsion systems will be more intimately associated with the energy source, rather than the thrust-producing device.

Many of the propulsion problems become more difficult when the mission requires a pilot or a passenger. Safety provisions, acceleration limits, hazard of radiation, or check-out procedures become more involved. From the propulsion standpoint, therefore, unmanned space flight will be easier to achieve at an early date.



The evaluation of the relative merits of one propulsion system over another and the selection of optimum propulsion system parameters will require the examination of many factors, some of them still unknown. Therefore, it is not possible at this time to make a general statement as to the optimum powerplant for space flight. Very likely the vehicle will be a multiple-stage space ship and carry more than one type of powerplant, each to be utilized for a specific portion of the flight. A relative evaluation of the optimum powerplant, therefore, will require an evaluation of specific missions.

For takeoff from the earth and other large heavenly bodies, and in many cases for landing also, a relatively high acceleration is required. For these functions, a liquid propellant rocket may well be adequate. A notable contribution to space flight can be made by improving and refining existing chemical rocket engines.

Presently known devices appear to make flights around and to the Moon, Mercury, Venus, and Mars theoretically feasible. Multiple-stage devices being

Ratio of thrust to weight versus specific impulse, sec., of different propulsion systems.

Mechanics Walter Pressir and J. W. Stewart set water-flow control valves on Rocketdyne's high flow bench used to test fuel control components in large liquid fuel rocket engines.

IDL NEW MULTIPOLE
PDM TELEMETERING COMMUTATORS

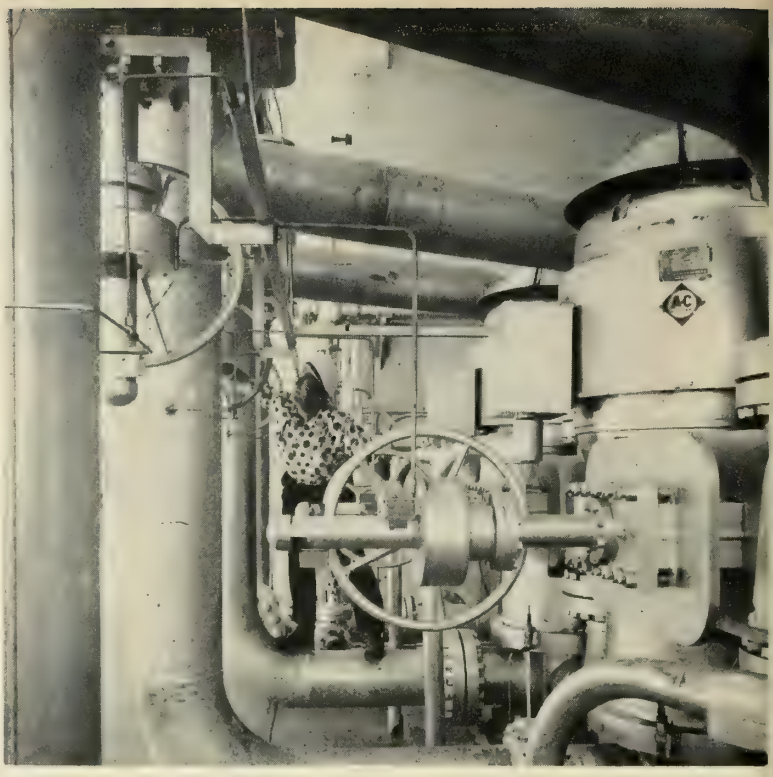
45 contacts @ 20 RPS
90 contacts @ 10 RPS
30 contacts @ 30 RPS
(Only 3¾" x 3⅝" x 6½" for 4-Poles)

Featuring:

LOW NOISE — 20 microvolts into high impedance.
LONG LIFE — 500 to 1000 hours of trouble-free operation.
NO BOUNCE — bounce-free through entire life.

Precision Design:

- Brushes supported on jewel pivot bearings.
- Brushes rotated by a 400 cycle, 115 volt, single phase 20 watt synchronous motor.
- Commutator fully undercut between segments, internally segmented.
- Cylindrical sections present only highly polished precious metals to the brushes.
- Internal wiring Teflon insulated and shielded.
- Entire case hermetically sealed.



Special Construction:

The multipole 45 x 20 and/or 90 x 10 PDM commutator is the newest IDL high speed, long life switch. Note these special construction features:

- Factory alignment of inter-pole phasing is provided to meet the IRIG Telemetry Standards.
- Pulse segment widths of 700 micro-seconds is a typical value for IDL manufacturing procedures.
- Pulse rise times of a few micro-seconds indicates the cleanness of "making."
- Either shorting or non-shorting operation can be provided.
- All contacts can be made available at the connectors for any desired external interconnections.
- Designed for missile and aircraft environmental conditions.

conceived can, with reasonable flight times, make it theoretically possible to fly missions to Jupiter and Saturn. There is no known powerplant today which would permit trips to Neptune or Pluto, or which would permit escape from the solar system in any reasonable length of time.

Several different propulsion systems will be considered here in very general terms.

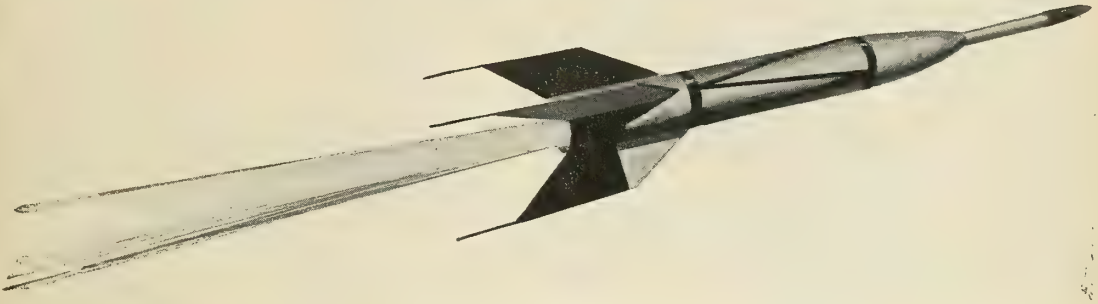
Liquid Propellant

The liquid-propellant rocket today is well developed and relatively well understood. It uses a chemical fluid and a chemical liquid oxidizing agent to create thermal energy which, in turn, is converted into a kinetic energy in a nozzle. Apparently there are no fundamental limitations as to size of this propulsion device. Many different forms and types have been produced.

Rockets which produce only a few pounds of thrust, as well as those producing many tons of thrust, are entirely feasible. The operating duration is generally short (less than 5 minutes) and the accelerations are relatively high, yet adequate, for giving good maneuverability in space flight. Takeoff and landing accelerations of 0.12 to 2.0 g's and space flight accelerations of less than 0.25 g are considered practical.

The liquid-propellant rocket is excellent for take-off from a body of large mass, such as the earth, moon, or the planets. A vehicle designed for these takeoff and return missions and for limited space travel to nearby planets will very likely require multiple stages.

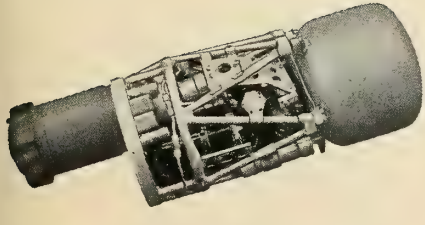
The high-energy liquid-propellant rockets are very similar except they give a somewhat higher performance. These rockets permit fewer stages or an improved vehicle mass ratio for a given mission, but they do present problems in logistics and engine design.



Nuclear Energy

A nuclear energy device achieves its reaction by ejecting a heated working fluid such as ammonia, helium or hydrogen. The energy released by the fission of uranium in a reactor is transferred to the working fluid which is vaporized by heating. The performance is limited by the maximum temperature that the nuclear reactor material can stand.

The radiation hazards inherent in this device from gamma rays, neutrons and alpha particles require special shielding provisions, particularly for applications where people are to be transported. Nuclear reactor heating offers a potential specific impulse improvement over the chemical propellant rocket by a factor of two or three. I



WHEN YOU WANT IT...

WHERE YOU WANT IT...

A DEPENDABLE SOURCE OF AUXILIARY POWER

A leader in the development of reliable, light-weight, self-contained monofuel auxiliary power systems for guided missiles and piloted high performance aircraft, Kidde now offers its combined engineering talents and precision manufacturing resources to firms interested in advanced applications of auxiliary power systems.

At present, Kidde has available turbine-driven units with horsepower of up to 200. These high speed units are designed to supply accurately regulated power at mean altitudes of 40,000 feet and up. However, they may easily be made environment-free, permitting airframe builders extremely wide latitude in systems design.

As a part of its power system development program, Kidde has gained wide experience with many monopropellants. These include ethylene oxide, hydrazine, hydrogen peroxide and propyl nitrate.

Whatever your present or future auxiliary power requirements, Kidde is ready to develop, test and manufacture equipment which will meet your exact specifications. For full information, write Kidde today.

general, the nuclear rocket appears to offer the same areas of application as the chemical rocket, except that the improved performance would permit a lower vehicle mass ratio and a smaller takeoff weight.

Free Radicals

If it becomes possible to store activated species of propellant, such as nitrogen or hydrogen, then it may be possible to attain a further improvement in performance by augmenting the energy release and reducing the molecular weight.

Solar Heating

The solar heating device collects radiation from the sun by means of a large optical system and converts this radiation to thermal energy. This energy is then permitted to heat a working fluid, such as hydrogen, to a temperature high enough to produce a reaction thrust.

This device has very low acceleration potential and a relatively low thrust output per unit of propulsion system hardware weight. They are not suitable for flight propulsion in the proximity of the earth or the planets. Acceleration will last over long periods of time and the thrust magnitude will probably always be relatively small. This fact limits the solar heating device to interplanetary space missions, and possibly to satellite sustaining missions.

Arc Heating

Electrical energy is discharged in an electrical arc which heats a working fluid, which is then expanded through a nozzle. The energy for the arc could emanate from various sources, such as captured solar radiation, a nuclear reactor, or batteries. Its thrust per unit engine weight is believed to be lower than that of the solar heating rocket.

Ion Rocket

Charged atoms (ions) are accelerated by electric fields to very high velocities. The electric energy is obtained from a nuclear reactor, batteries or a solar radiation system. The thrust-to-weight ratio is probably even smaller than that of the arc heating or solar heating device and the rocket is again limited to space missions.

Should the specific outputs of the powerplants mentioned be limited to perhaps twice their present value, then it follows there are no existing powerplants which would make possible travel to another star or even travel to the outer planets within the lifetime of a man in a space ship. The crew would die before the journey was even half completed. It will be necessary to devise new, more powerful, rockets to achieve flight to the stars.★

Bench-Top Proving Ground for Missile Controls!

Directional controls for guided missiles . . . tracking and scanning devices . . . cameras . . . range finders—how well they work depends greatly on the efficiency of their optical systems.

Recognition Contrast Rendition equipment at B&L completely eliminates human error in measuring optical efficiency. Its direct-reading scale automatically rates how well an optical system can "see" under lighting conditions of variable intensity, as experienced in actual use. Accuracy: 1/40th of a wavelength of light!

This instrument is not for sale. It is part of the unique quality control system that has made Bausch & Lomb the dependable optical source.

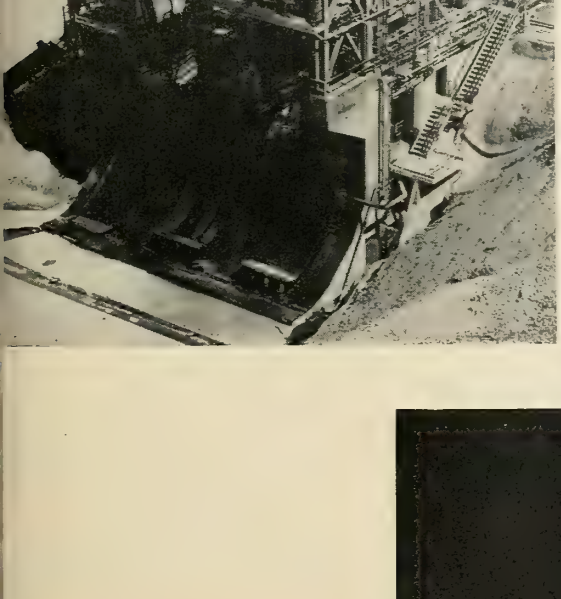
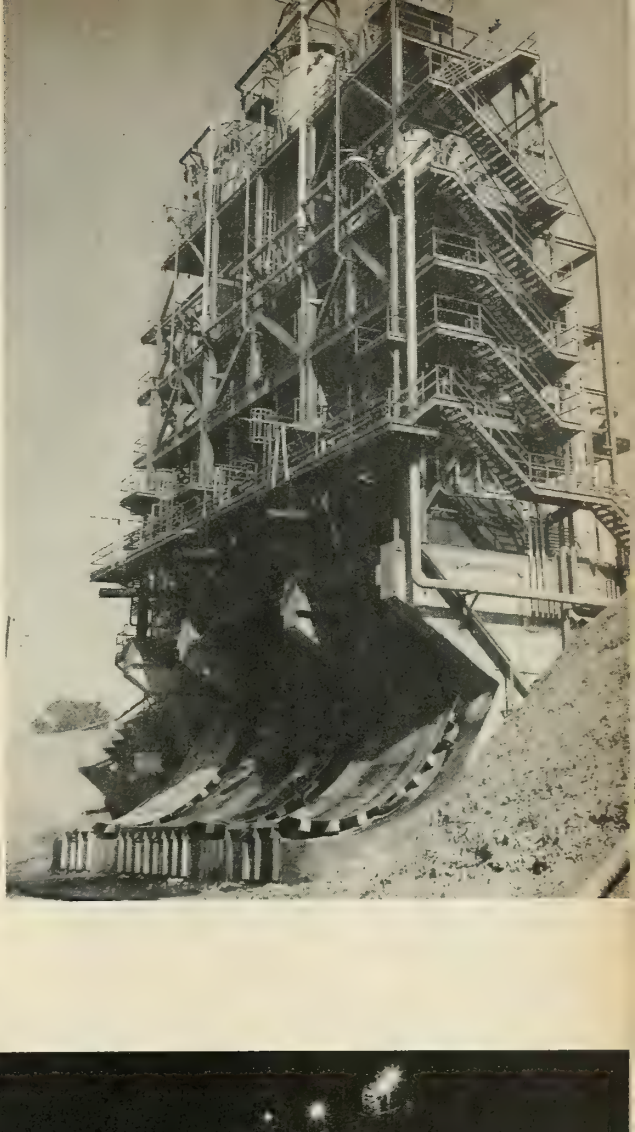
POWER UNLIMITED . . .



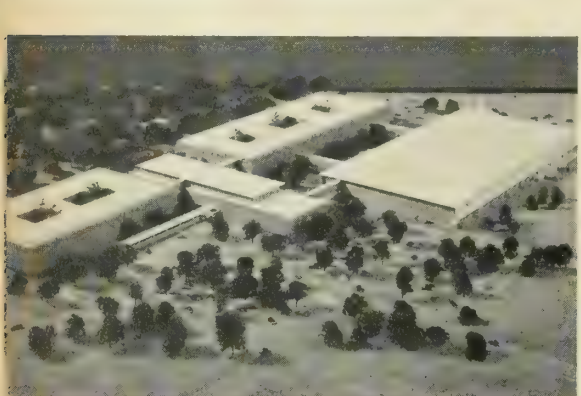


Big missiles mean big engines. And big engines mean big tes facilities. TITAN is a big missile—an ICBM designed to carry 300 pounds or more of thermonuclear warhead some 5000 miles. Aerojet General Corporation, TITAN prime propulsion contractor, has buil eight giant static test stands like those shown here at Sacramento Calif. Immediately above is the simulated high altitude test chambe Other views on this page show actual tests under way. Aero jet is not allowed to comment on whether any are TITAN engine

t doesn't take much examination of these ictures to see that rockets are an expensive usiness. The tons of concrete and close- olerance, high strength structure, water sup- lies for cooling the blast deflectors and all he measuring and calibration equipment nake these multi-million dollar monsters. The est stand to the right, shown both by day nd night, can take engines of over one mil- ion-pounds thrust. It cost $3 million to build. hough no one-million-pound thrust engines ave yet been fired, it may not be too long efore this is done. Unofficially, it's been tated that liquid engines of over 300,000- ounds thrust have already been tested. And elsewhere in this magazine, it is stated hat engines of virtually any thrust that may e required can be constructed. From a tate-of-the-art viewpoint, there's no limit.

TO NOURISH AN IDEA

Dr. Peter J. W. Debye, professor emeritus of chemistry at Cornell University, and Dr. Lloyd P. Smith, President, Avco Research and Advanced Development Division, discuss the Avco research program prior to Dr. Debye's recent colloquium at the Division's Lawrence, Massachusetts, headquarters.



THE FULL IMPACT of science on man and his economy is beginning to be realized. Past achievements, translated today's technology, are transforming the world.

In the dynamic environment man has created, his civiliza cannot stand still. He is committed to move forward to scientific breakthroughs that lay the foundation for a st economy based on advanced technical achievement.

Creative scientists and engineers, working together in an i lectual environment where ideas can be freely expressed freely explored, will shape this new economy. Avco is crea the environment in which uninhibited thinking men can se out new problems and work toward their solution. A new rese center will provide a physical environment, facilities and co with stimulating minds to nourish the best ideas that each contributes.

Some of America's foremost scientists and engineers are at here. Consultants, like Dr. Peter J. W. Debye, contribute thr colloquia and the stimulation of the inter-disciplinary cur imperative to high-level scientific performance.

Avco's scientific approach to urgent national defense prob has already brought advances in high-altitude, high-speed f missile re-entry, aerodynamics, heat transfer, materials and areas. Practical problems have been solved; scientific hor have been widened. But the greatest challenge at Avco lies work yet to be done.

Pictured above is our new Research Center now under construction in Wilmington, Massachusetts. Scheduled for completion in early 1958, this ultramodern laboratory will house the scientific and technical staff of the Avco Research and Advanced Development Division.

Avco's new research division now offers unusual and exciting career opportunities for exceptionally qualified and forward-looking scientists and engineers in such fields as:

Science:
Aerodynamics · Electronics · Mathematics · Metallurgy
Physical Chemistry · Physics · Thermodynamics
Engineering:
Aeronautical · Applied Mechanics · Chemical · Electrical
Heat Transfer · Mechanical · Reliability · Flight Test

RESEARCH & ADVANCED DEVELOPME

LOX . . . Mainstay Oxidizer for the Missile Age

By William H. Thomas, *Assistant General Manager*
Process Equipment Division, Air Products, Inc.

TOMORROW'S DEFENSE depends on a wide variety of highbrow systems. With scientific and industrial tools accompanying advanced military units in so many ways, cryogenic liquids such as oxygen and nitrogen have become as familiar in today's armed forces as ham and eggs.

LOX occupies a position of leadership mainly because it does one job supremely well. As missiles continue to influence our major defense efforts, only those systems with the highest performance capabilities may be considered for certain key jobs.

For packing energy into small volume with minimum mass, nothing yet developed can successfully challenge liquid propellant rocket systems. High specific impulse and ease of storing liquids in irregularly shaped spaces provide a very potent missile combination.

Why should one oxidizer stand out among the wide number of available liquids? The answer is practicability. In addition to high performance, LOX answers more of the cost, storage, handling, safety and logistics requirements than perhaps any other material contemplated for volume application.

More for Less

Available for pennies per pound, LOX costs less than coal in many areas. Few oxidizers are equally available for purification and refrigeration (atmospheric air is available everywhere), hence more reasonable in their cost than LOX.

Insulated storage facilities are available for LOX which limit losses to ½ to 1 per cent per daily use both for hauling and stationary storage. Storage aloft is not a serious problem as the rate of consumption in most missile equipment is so rapid that vaporization losses are inconsequential.

Handling LOX is similar to handling other fluids of high vapor pressure. As in any other such liquid system, for example, gasoline, absolute sealing can invite dangerous pressure buildup. Simple venting is the rule. LOX may be pumped, valved, filtered, vented and even spilled like most other warm or cold liquids. LOX has been handled commercially and profitably for a long time. Techniques developed over long years in the commercial oxygen industry are successfully practiced today throughout the military.

Safety is a critical factor in selection of materials and methods for defense. Systems so hazardous to personnel as to include high risks of nonperformance could be catastrophic in a time of real emergency.

LOX has a proven record of safe storage and handling. Warm vapors emanating from LOX are breathable and noncorrosive. Oxygen is used as a therapeutic agent in hospitals and is assuredly not poisonous. Combustion products of LOX with most fuels are also generally nontoxic and safe for breathing, so that personnel need not be restricted from access to a launching site because of atmospheric contamination.

No fuel-oxidizer combination is of any value unless available when and where it's needed. Success of any military operation depends on the effectiveness of supply lines and freedom from dependence upon questionable supply sources.

Today, LOX is available wherever standard highway trailers can be put down on a firm footing. Portable LOX plants, currently in production, are available for generating LOX from diesel fuel and atmospheric air anywhere on the face of the globe.

The efficiency of LOX production facilities today is such that one pound of diesel fuel may produce two pounds of LOX. Once a portable LOX facility is installed at an advance base, further problems of supply amount to the effective delivery of standard diesel fuel.

In summary, LOX is available at very low cost, may be handled and stored effectively by routinely trained personnel, and may be produced anywhere in the world where a supply of fuel is available for an internal combustion engine.

On-Site LOX Generation

For many years, most oxygen was manufactured in central generating plants, compressed as a gas and distributed in heavy cylinders. Later, liquid LOX became commercialized because it afforded more efficient distribution. However, despite handling economy, delivery costs still soared as a result of extensive manpower needs and high labor costs.

Improvements in manufacture and the development of advanced types of on-site oxygen generating equipment brought a significant change in the shipping and storing of oxygen. Today, most large industrial consumers prefer to establish oxygen generators within the boundary limits of their own plants, saving transportation costs and utilizing free local air.

LOX requirements, dating back to Goddard's experiments on rocket engines and missiles in the early '20s, were supplied in relatively small quantities from commercial sources. As the U.S. military missile program gained momentum, it soon became apparent that vast quantities of LOX would be required at areas remote from existing large oxygen producing locations. Thus, the on-site generator, born of industry's needs for cost reduction, came to serve military requirements.

Military 75 Ton/Day LOX Generators

These units are designed for meeting the following basic requirements:

1) Low cost and high operating efficiency.

2) Minimum of utilities.

3) Reliability for continuous operation.

4) Transportability.

Large LOX producing facilities which meet the above requirements are currently "on-stream." Each facility is made up of individual LOX generating units which are considered to be a maximum size compatible with railroad and highway transportability or packaged components. Each LOX generating unit produces 75 tons per day of liquid oxygen simultaneously with 7.5 tons per day of liquid nitrogen, each at 99.5 per cent purity.

Multiple LOX generating unit facilities are currently in operation and under construction at stations in California, Florida and Colorado.

The 75 ton/day LOX generator employs a high pressure cycle, with certain process and equipment innovations designed to combine lowest initial investment with highest operating efficiency.

Filtered air is compressed in a multi-stage compressor to 2000-3000 psig. Between the second and third stages of compression, the air is passed through a caustic scrubbing system to remove carbon dioxide from the air stream.

Air leaving the fifth stage of the compressor passes through a desiccant-type drier system to remove moisture from the air. After the air drier, the air stream is split. One stream passes through the main heat exchangers, being cooled by effluent gases from the distillation column and is expanded through a valve in the high pressure column.

The other portion of the air stream is expanded from compressor discharge pressure to an intermediate pressure through a reciprocating expander, warmed through coils in the main heat exchanger and expanded into the high pressure column through a centrifugal expander.

A double rectification column is used. Crude liquid oxygen from the high pressure column is passed through hydrocarbon absorbers before being expanded to the low pressure column. Liquid nitrogen product is withdrawn from the stream which also provides liquid nitrogen reflux to the low pressure column.

Liquid oxygen is withdrawn from the bottom of the low pressure column. Effluent nitrogen-rich gas from the low pressure column is warmed in the main heat exchangers against incoming air and discharged to atmosphere.

A portion of the warm, effluent gas is used to load the centrifugal expander and is then used for reactivating the air driers, hydrocarbon absorbers and reciprocating expander oil filters.

Actual operation of 75 T/D LOX generators have resulted in an over-all cycle efficiency (power cost) of approximately 780 Kwh/ton of LOX plus liquid nitrogen. Actual operating costs for large quantity production rates have been reduced to approximately 0.7 cents per pound of delivered LOX and liquid nitrogen.

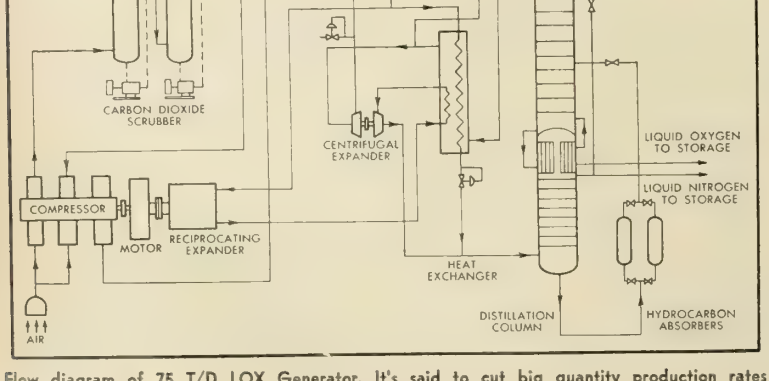
The 75 T/D LOX generator is designed to operate with electrical power as its only essential utility.

It is required that these LOX generators operate in remote areas, often where no cooling water is available. Therefore, the air compressor is equipped with large air-to-air inter- and after-coolers. It is important that the generator have a high reliability factor.

Several units have been in operation for over a year with very high "on-stream" factors. Actual production has been about 10 per cent over the rated capacity.

Because the use of the LOX may be cyclic with high peak requirements and also periods of full storage, it is very important that the generators can be taken "off-stream" and put back "on-stream" with a minimum delay in production.

Experience has shown that approximately five hours are required for a single warm generating unit to be placed in full production. Approximately one-half is required to re-establish production from a "cold" start.



Occasionally, any high pressure cycle LOX generating unit requires defrost of the main heat exchangers. This unit is designed so that the heat exchangers can be defrosted independently of the main cold equipment. The total time required to defrost the main heat exchangers, and cool down again to normal LOX production, is five hours.

The size of the LOX generators developed for the Air Force missile program was dictated by the transportability factor. Even though the generator is large, the components including "factory packaged" cold boxes are all capable of transport by rail or low-bed trailer which permits a minimum of erection time and reduces erection costs. It is estimated that the cost of a factory packaged cold box of this size is about 75 per cent of the cost of a field assembled cold box.

The importance of LOX in this country's missile program is firmly established. It is already being produced in large volume for the missile program by the most modern and efficient type of equipment available and at a cost which assures its expanded use.

Vast improvements have been made in rockets and missiles since Germany, in military desperation, launched its first V-2 rocket against England. The efficiency of a missile depends on many things. Not the least of these is the fuel oxidizer. It must fulfill many exacting requirements.

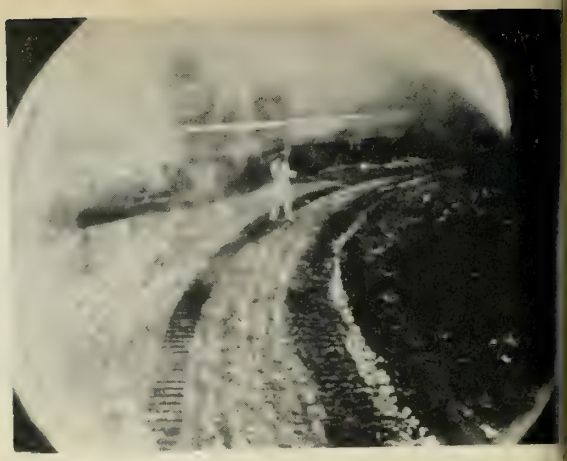
Technological advances in low temperature processing have brought LOX production to a high point of safety and efficiency. It can be produced anywhere and transported safely in large volume. We at Air Products are proud to be a part of our country's missile program—and look forward to new developments in the field of applied cryogenics as it affects this vital defense effort.★

Flow diagram of 75 T/D LOX Generator. It's said to cut big quantity production rates to about .7¢ per pound of LOX and liquid nitrogen. Designed to run by electric power.

ENGINEER STILL AT WORK

is 2:42 A.M. and somewhere a man lies awake, mentally developing endless equations—studying prints and ıematics his tired but sleepless mind projects upon his bedroom ceiling. rhaps he is the man who will be responsible for a missile of unbelievable range d accuracy—for a faster, better aircraft to make possible the peaceful sleep of ıntless millions.

ere isn't much glory in the work he is doing. He wears no wings pinned to his rt as he bends over his drafting board. He never makes the headlines nor is his picture ead in the news magazines. Day after day, people pause momentarily—look up—but seldom lize the vapor trail they see in the sky once existed only in the mind of a man—an engineer with vision.



ı salutes the engineers of the nation, dedicated to the task of building a stronger, happier America. We at Sun join h the aeronautical and astronautical industries in urging young men and women to prepare themselves for this at profession—now on the threshold of challenging the universe! Sun is proud, too, of the role it is playing in the ft progress toward aeronautical and outer space supremacy—helping to make the engineer's job easier by furnishing ı with vital testing tools and equipment. If You have a testing problem—if You need the right equipment to make r job easier—we suggest you put our engineers to work.

CURE FOR CRAZY MISSILES

Once airborne, "sick" autopilots are a cinch to spot. Even the boys at the roadblocks can spot them. The trick, of course, is to design those bugs out of the guidance system long before the count-down. It's easy to say. And it's easy to do too . . . with the SERVOSCOPE® servosystem analyzer. You "fly" the complete system through the entire performance envelope, and spot all of the weak points in no time flat with Servoscope.

That's why it's SERVOSCOPE everytime. That's why SERVOSCOPE is THE standard. Most missiles, and nearly every control system, are checked-out with the SERVOSCOPE.

SERVOSCOPE is the *only* servosystem analyzer that performs *all* of the checks necessary for guidance systems . . . an equivalent check-out with other means takes at least six separate instruments and assemblies. That's why you'll find the leading missile builders and suppliers using Servo Corporation's units in their plants.

An entirely different part of the missile's speed record is set by the SERVOBOARD® electromechanical assembly kit. This portable, versatile arrangement expedites mock-ups of any Servosystem and slashes transition time from drawing board to missile "shoot."

Servoscopes and Servoboards can play vital roles in *all* types of servosystems. Want a demonstration? More data? Just send your request to *Technical Information Group, Room B, Servo Corporation of America, 20-20 Jericho Turnpike, New Hyde Park, New York.*

Non-Metallics for Missiles

Non-Metallics Take over Where Metals Leave Off

By John H. Lux* and Robert L. Noland*

THE RAPID GROWTH of the rocket and missile field has placed a great emphasis on production. Severe environmental conditions have resulted in a heavy emphasis on non-metallic parts as construction material. These can stand higher temperatures, are lighter in weight, better insulators, easier to fabricate, and have a wider variety of properties than metals. Among the missile non-metals are a family of proprietary materials made by Haveg Industries, Inc., and its wholly owned subsidiary Reinhold Engineering and Plastic Co. These are now used for components in 17 different types of missiles.

Proprietary materials such as Rocketon and Missileon are fabricated in pieces from ¼-inch in dimension, weighing only a fraction of an ounce, up to single pieces weighing as much as 50,000 pounds each. They may be finished by standard metal machining procedures and, in general, tolerances are fairly close to those encountered in the metals machining field.

Properties of these materials at temperatures about 14,000°F are still undisclosed, but in tests conducted, performance was considerably better than for magnesium oxide. During a 20-second run at temperatures ranging from 9,000°F up to 12,000°F, a half-inch thick disc of this material showed very little erosion and no cracking. This suggests the material could play a major role in the solution of severe reentry problems.

Haveg compounds are not metals, plastics nor ceramics, but a combination developed for high temperature operation. At high temperatures, the organic binder is pyrolyzed or reacts slowly with the high melting inorganic silicates, giving a surface which has the ability to resist erosion and the conductance of heat while most of the energy is reflected from the surface and subsurface back into the flowing stream of gases.

Among the items made on production schedules at the present time are blast tubes for use at temperatures approaching 6000°F., insulators, insulator adapters, motor cases, rupture discs, throats, jet vanes, jetevators, combustion chambers and nose cones.

Production techniques already enable nose cones up to 108 inches in diameter to be fabricated on regular plant equipment. Several of these can be made daily and at very low cost.

Production Techniques

There are at least ten different methods of handling the materials; extrusion, internal spinning, external spinning, indenting, casting, pressure molding, transfilling, hand lay-up, bag molding and filament winding. In addition, there are the same finishing operations used for metals, such as cutting, turning, threading, drilling, tapping, planing, milling, grinding, and coating.

While extruding is familiar to everyone in the metals and thermoplastic industry, it also works with thermosetting materials such as Rocketon and Missileon. The compound is forced through a cold or heated die or mandrel to form the shape desired, and the material cures on, or shortly after, emerging from the die. This is used, for example, in making blast tube insulation.

Units up to 12 inches in diameter and up to 20 feet in length may be produced in this manner either batchwise or continuously. In instances where post curing or post forming is desirable, this type of operation may be followed by pressure molding, indenting or other processes.

For large insulation systems or blast tubes up to 12 feet in diameter, extrusions are not feasible. Internal spinning is necessary. Here high temperature compounds are "spun" to an outside mold surface and compacted by centrifugal force or by pressure.

Pieces may be used in the steel structure in which they are spun, or may be removed by means of mold release and utilized unsupported. An example of process was in the coating with Missileon of the interior of a steel missile tube six feet long and six

Airborne Ultrasonic Liquid Level Sensor

Here is a new light weight, highly accurate liquid level point sensor for aircraft, missile fuel and oxidizer systems, and propellant control. Designated Model RC-1A, it operates on ultrasonic principles to detect the presence or absence of liquid at a predetermined level. The basic sensor consists of a miniaturized hermetically sealed ultrasonic probe, measuring approximately 2" in length and 11/16" outside diameter. The probe weighs only one ounce and is always at the ambient temperature of the liquid being gaged.

FEATURES

A response time of less than 10 milliseconds
Negligible power drain
Accuracy better than 1/64"
Sub-miniaturized
Light weight
Absolutely no spark or radiation hazard

An associated plug-in hermetically sealed control unit contains a sensitive relay capable of performing a control or indication function. Weight of this unit is only six ounces.

Various modifications are available to meet your particular needs. Probes capable of sensing cryogenic, highly corrosive, or radioactive liquids are available. Let us know your specifications. There's an Acoustica representative to help you anywhere in the U. S. and abroad. Mail your request for information with your Name, Position, Company, and address to:

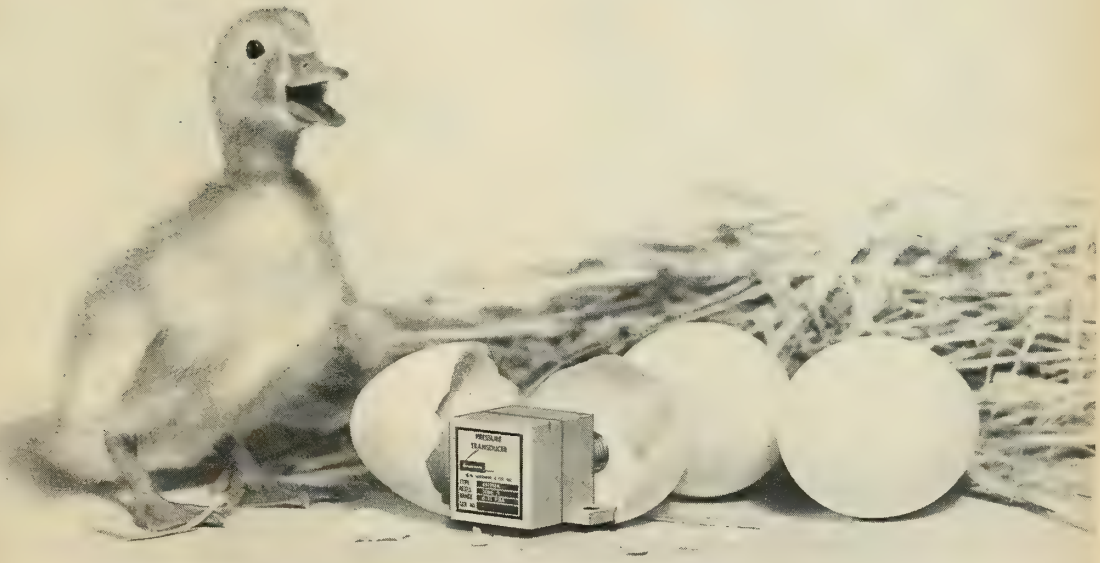
MATERIAL TYPES



TYPE	USES	CONDITIONS
Rocketon	Missile Insulation Insulator Adapters Blast Tubes Nozzles Flame Deflectors	Up to 6000°F., several minutes, up to 3000°F., for one hour. Mach 0.1 to Mach 1
Missileon	Same as Rocketon Protective Insulation	Capable of standing *much* higher temperatures than Rocketon at low gas flow
Planeton	Jet Vanes Jetevators	Up to Mach 3 with temperatures in range of 5000°F., permanent operation at 550°F
Satellon	Same as above	Higher temperatures operations than Planeton but for lower gas velocities
Orbiton	Missileon reinforced with glass cloth	Same as Missileon
Mercuron	High temperature electrical insulation, Jet insulation	Designed for permanent operation at 700°F
Terran	Adhesive for assembly of insulating materials to steel	In conjunction with insulating materials has withstood the same conditions of the above insulations
Reinhold Epoxies	Structural parts in missile and aircraft applications	Environment temperatures under 300°F
Reinhold Polyesters	Same	Environment temperatures under 200°F
Reinhold Diallyl Plthalate	Electronic parts where low dielectric constant and low water absorption are required	Temperature under 200°F
Reinhold Phenolic Glass	Same as Rocketon	Up to Mach 3 with temperatures in range of 4000 to 5500°F, Continuous operation at 450°F
Reinhold Filament Wound	High strength of structural parts in missile and aircraft applications	

inches in diameter with a closed end. The spun interior was cured and machined right in place and then forwarded for loading with propellant. In both internal and external spinning, an outstanding resistance to erosion is developed by virtue of the fact that the filler structure is oriented circumferentially to the direction of gas flow through the tubes. Erosion resistance is improved up to ten times previous best values.

In contrast to internal spinning, there is no limit in size to external spun pieces. For example, the whole 8-foot length of a rocket unit was coated with Missileon ½ inch thick (including the nose cone), followed by a polishing operation which provided a brilliant marble-like highly reflective surface. Rolls, 12 feet in diameter, have also been coated. Venturi sections up to 20 feet in length have also been made, and shapes such as elbows are

TALK ABOUT MINIATURIZATION!

...Giannini has really hatched one this time.

almost spaceless... almost weightless

THE "ONE CUBIC INCH" PRESSURE TRANSDUCER —so small that 93 instruments won't quite cover this ad—packs king-sized performance in its 1"/side case.

Developed for the Vanguard Earth Satellite, this potentiometer output transducer provides a high level output proportional to absolute, differential or gage pressures to 50 psi. Resolution is better than 300 wires (0.33%) and weight is *less* than 3 oz.

For full details, please write for Data Sheet No. 451218, the "Cubic-Inch" Pressure Transducer.

LAND POWER takes on new offensive strength by employing surface-to-surface missiles to pinpoint retaliatory blows against aggressors and destroy selected land targets.

AIR POWER is made more formidable by use of air-to-air missiles to intercept the high-speed attacks of enemy jet fighters or bombers.

SEA POWER is strengthened and its range extended by surface-to-missiles designed to intercept attacking aircraft far from our shor

MISSILES:

On their precision may rest the fate of the world

No matter how many missiles a nation builds, no matter hc much they cost, the effort is useless if they fail to deliver warhead squarely on the target. On the other hand, the nati possessing missiles of known precision has one of the great powers on earth to prevent wars. No aggressor could affc the swift and deadly retaliation such missiles assure.

Whether a missile is designed to intercept a bomber at sh range – or demolish a target in another hemisphere – effectiveness depends to a large extent on the performance the gyroscopic, electronic, hydraulic and mechanical syste which guide it. With new missiles capable of reaching 5,(mph within *seconds* after blast-off, these ultra-sensitive cc ponents must survive violent stresses and hold the missile its true course to the exact moment of impact.

Through the foresight of America's military strategists missiles now constitute a strong power in maintaining wc peace. Our immunity to attack will continue, however, only long as their precision remains superior. Sperry's contributi to our missile program range from instrumentation and cc ponents through major subsystems like radar and iner guidance, to complete missile weapon systems and autom checkout equipment.

DIVISION OF SPERRY RAND CORPORATION

easily converted by spinning first in one direction and then changing the axis and completing the job. External spinning also allows one to build up the strength by adding additional wall thicknesses or by inclusion of reinforcing materials such as glass cloth or other fibrous materials.

Indenting is a general process where a clay-like high temperature compound is forced, under low pressure, to conform to an irregular shape. Using these techniques, such peculiar devices as angular exhausts, angular tail cones, reversing chambers, auxiliary tubes and igniters may be installed in rocket motor systems.

Casting techniques are useful for filling a shape for either protection from heat to provide electrical insulation or to provide extra strength or rigidity.

A large amount of engineering and technical effort has been directed toward the development of high pressure molded parts containing large percentages of inert fillers, such as glass and asbestos. In the fabrication of these parts, hardened chromium-plate match-metal steel dies are employed.

These dies are usually designed to yield parts that conform to the drawing requirements without subsequent machining operations. By proper control of the die design it is possible to mold satisfactory parts having very close dimensional tolerances. For example, with high pressure molding, Planeton has replaced a molybdenum-tipped graphite jet vane. The molded vane is not only more economical to produce but also has superior performance characteristics in the jet stream.

Many other rocket and missile parts are being produced by high pressure molding operations, such as nozzle and throat sections, exit cones, heat insulators and various other motor internal components. Molding requires high temperatures and pressures varying from 100 to 15,000 psi. The actual molding pressure, temperature and cycle is a function of the parts design as well as the type of molding material utilized. This method is particularly valuable for mass production. The size can vary from a few grams to as high as 450 pounds.

Great strides have been made recently in the molding of close-toleranced parts for the electronics industry. For example, in one large electronic molding there are approximately 100 rare-metal plated inserts positioned relative to each other by close (less than .001 inch per inch) dimensional and angular tolerances. The tolerances are such that it is necessary to maintain tolerances of less than .001 inch per inch. This part was put in production at a cost far less than that of the hand-fabricated part.

In areas where a moderate number of parts are needed (normally 50-100), it is too costly to buy a complete match metal die mold and to set up on a production basis. These units may be made by buying an inexpensive steel mold which is then filled by transferring the proper amount of compound by means of a hydraulic ram. Once the mold has been filled under pressure, it may be moved to curing ovens for final completion.

When it is impossible to utilize the existing mechanical techniques because of the size and shape of a unit or for the fabrication of a single model unit, hand lay-up is often the simplest. Skilled operators, using melamine, epoxy, phenolic or polyester resin, impregnated upon glass or other fibrous materials, actually make the compound conform to the shape of a surface or mold, and put on as many thicknesses as desired to build up the desired surface. Shapes 250 feet long and 20 feet in diameter are common. In such a process it is easy to install honeycomb and other inserts.

Bag molding is a process of pressing a previously prepared lay-up between a fixed form and a flexible bag by application of vacuum to the area between the mold and the bag or by use of steam or other fluid pressure. Both wet and "prepreg" type lay-ups may be used. In contrast to match metal die moldings, where both sides are finished to good surfaces, only one side is in the finished state. Heat exchanger ducts, for example, can be manufactured this way.

Filament winding consists of feeding resin-impregnated continuous glass filaments to a rotating mandrel, with the external dimensions of the mandrel conforming to the requisite internal dimensions of the desired part. By use of the continuous glass filaments it is possible to realize structural strengths considerably higher than those obtained by other fabrication methods where glass filaments are utilized. It is possible to realize tensile strength as high as 150,000 psi under ideal conditions where the filaments are all aligned in the same direction.

By varying the alignment of the filament in the fabricated structure, it is possible to alter its structural characteristics. For example, the 150,000 psi strength condition is achieved in a cylindrical vessel where the fibers are oriented to resist only hoop loads. For a closed end pressure vessel, it is possible to align the fibers in the direction of the principal stress and thus obtain the ultimate structural use of the glass filaments. The resulting pressure vessel

OPEN DEWAR FLASKS

For Low-Temp Liquids

Exclusive Radiation Shield Keeps Low Boiling Point Liquids Longer

These sturdy, shielded-arc welded all stainless steel (18-8 type 304) open Dewar Flasks attain the highest degree of structural strength and thermal efficiency. The internal wall surfaces are treated for optimum reduction of radiant heat transfer. In addition, these flasks feature an exclusive radiation shield which is also treated on both sides, effectively reducing the remaining radiant heat transfer by approximately 50%. With a hard vacuum of 10^{-5}_{mm} of Hg or less the effectiveness of Hofman Dewars, in containing liquid air, oxygen, nitrogen and argon is unsurpassed by any other open vessel.

can have a hoop-burst strength as high as 80,000 psi, the limiting design feature being the method by which the end closures are attached to the cylindrical section of the vessel.

Since the glass filament wound structures have a low density, approximately .067 pounds per cubic inch, and relatively high strength characteristics, they can be utilized to great advantage in missile and aircraft applications. For example, Reinhold designed, developed and put into pilot production, an all-plastic, small caliber ordnance rocket. Its performance characteristics were far superior to those obtained with a similarly designed all-metal round. The effectiveness of the all-plastic round is demonstrated by its reaching a burnout velocity of 3800 fps as compared to 2300 fps for the metal round.

This method of fabrication makes it possible to obtain excellent productivity. Of 8000 four-inch diameter couplings currently no units have failed the 100 per cent hydrostatic pressure test. This unit will satisfactorily withstand an external pressure in excess of 5000 psi.

Production methods and costs often depend on quantity. For example, a prototype might me made for $100 by an indenting process using a cheap wood mold. Following the success of such a unit, 50 might be made for $50 each, using a low cost metal mold. Finally, production of 5000 units would be carried out at $20 each using a match metal die mold in a large automatic press. Haveg's large stock of over 30,000 different molds enables them to make almost half their new items with an insignificant mold charge.

For machine finishing, cemented carbide tools of the harder grades and coarse abrasive wheels are preferred. Common tool steel may be used, but it dulls rapidly. Another technique is to finish each part independently, assemble in the plant and then perform a second finishing operation. Blast tubes can be cemented into the steel chambers by means of Terran flexible cement. The joint between the two insulation materials is then made by indenting with Rocketon cement which is of the same composition as the insulation and will withstand operation up to 6000°F., at sonic velocities.

These materials have many advantages over graphite as a material of construction. Probably their most important property is their high degree of reflectance at high temperatures. Since a major portion of the heat transfer at temperatures above 2500°F. is by radiation (note the high value of the T^4 factor in the Stefans-Boltzman equation), the degree of whiteness or blackness is extremely critical. While

THIS JOB CAN'T WAIT!

The computer system for the Intermediate Range and ercontinental Ballistic Missiles being built by Remington Rand ivac is vital to national defense.

The United States must be ready to deliver a swift and shing counterpunch in case of enemy attack. The Univac® tem would guide such missiles as the Air Force's TITAN l THOR on their missions of retribution.

There is immediate need for qualified men in Univac's highly ential ICBM program. Here is your opportunity to take t in a fascinating, crucially important project . . . your portunity to find a permanent position and limitless ure with Univac — world leader in the field of tronic computers.

Immediate Openings for:

ELECTRONIC ENGINEERS for component engineering, transistor circuit applications, circuit analysis and design, reliability, engineering test, component evaluation, quality control and specifications.

MATHEMATICIANS, BS, MS, and PhD levels for programming, math research, statistical analysis, data conversion. One to seven years' experience.

PHYSICISTS, BS, MS, PhD levels for research and development of systems and circuitry of digital computers, for evaluation of component reliability, and for physical research including evaporative thin film research and other solid state phenomena.

Also, other non-military career openings at our laboratories in Philadelphia, Pa., Norwalk, Conn., and St. Paul, Minn.

When tomorrow's rocket takes off for a destination in space, its propellant will undoubtedly be a high energy fuel-oxidant system . . . and the oxidant may well be ozone.

In the comparatively short period since the development by Welsbach of dependable tonnage ozonators, the applications of this versatile low-cost oxidant have broadened to include practically every industry. It is recognized for its specificity and purity in chemical synthesis reactions and has made possible increased yields of high quality products from cheap and abundant raw materials.

Specific uses for Welsbach ozone include the production of lubricants for high-speed motors and jets and the oxidation of corrosive chlorides in nitric acid recovery following atomic fuel extraction. Ozone also effectively removes phenol and cyanide from industrial wastes, and improves the oxidation characteristics of mineral oils.

These and numerous other uses indicate that the scope of applications for Welsbach ozone is unlimited. Through constant research, Welsbach continues to enlarge the field for ozone as an oxidant. With an unparalleled background in the design and construction of tonnage ozone plants, Welsbach offers you a long and varied experience in ozone application.

Call or write us today for help in solving your oxidation problem.

Write for this booklet on Welsbach Ozone Generation for Industrial Application. Please indicate company and title.

Circle No. 91 on Subscriber Service Card.

the reflectivity of most materials ranges from 40 to 70 per cent, Rocketon and Missileon have reflectivities of 95 per cent or above at 3000° to 5000°F. This compares with a factor of 50 per cent to 52 per cent for graphite under the same conditions.

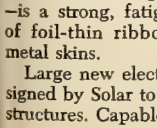
A further advantage is that Haveg's insulating value is many thousand times better than graphite so that in addition to not absorbing the heat, any heat which is absorbed is not passed on to cause deterioration to other parts.

Other advantages over graphite include: Brinell hardness of about 42 where graphite is so soft that it does not even appear on the scale; fabrication into an unlimited number of shapes and sizes; thermal shock resistance—pieces of Haveg have gone from room temperature to 5000°F., in a period of a few seconds, in many hundreds of tests without failure.

Molded pieces of Haveg may be joined to other pieces or have igniters or other units cemented in after formation. For example, where it was desired to place an igniter in an afthead insulator of Rocketon, all that was necessary was to drill a hole in the Haveg of the proper size, insert a small 2-inch Haveg tube and then apply Haveg Rocketon cement. In one hour the job was complete and ready for use. With most other construction materials, this is an impossible feat.

Another limitation of graphite is its use with chemicals. Haveg is completely resistant to most of the chemicals used in both liquid and solid propellants. Its silicate structure is chemically inert to everything except hydrogen fluoride. And, in instances where HF is encountered, there is a grade of Haveg which will also give satisfactory performance here.

Finally, it is well-known that graphite, in an oxidizing atmosphere reacts to form CO^2 or CO and this reaction begins at 500°F., in air—700°F., in steam and 900°F., in carbon dioxide. Rocketon and Missileon are unaffected by either oxidizing or reducing atmospheres up to 5000°F. Beyond that temperature, little is known.



Rocketon for nuclear application has been tested at 10^9 roentgens for a period of several months. Examination of the test samples showed no appreciable change in chemical or physical properties. Oak Ridge National Laboratories predict that Haveg Rocketon will withstand higher levels of radiation. In equipment exposed to low level radiation, the strength approximately doubles.

A big advantage of working with a family of materials is the fact that properties can be varied over a wide range to suit requirements.★

Solar Advanced Technology

All-metal honeycomb sandwiches solve aircraft heat, weight problems

Aircraft and missile designers continually increase their demands for lighter, heat-resistant materials. Solar technology is helping to solve this heat-weight problem with all-metal honeycomb sandwiches. The new product—called Solite® —is a strong, fatigue-resistant structure of foil-thin ribbons bonded between metal skins.

Large new electric furnaces were designed by Solar to braze these sandwich structures. Capable of operating at high temperatures with extreme purity of atmosphere, the furnaces incorporate many features which make them virtually unique.

Tailor-made for use in advanced aircraft and missiles, Solite offers a practical solution for exacting heat and weight requirements. For 30 years Solar has pioneered in welding and brazing high alloy steels that will stand up under extreme service conditions. Perhaps Solar can bring a fresh viewpoint to your difficult metal-working problems. Write Dept. D-78, Solar Aircraft Company, San Diego 12, California.

Missile Business

By Seabrook Hull

A DECISION ON WHO GETS WHAT in the way of big missiles is due within weeks—by the end of September in fact. Announcing the results of the evaluation now under way will be the first major missile action of the new Secretary of Defense, Neil McElroy. The currently appointed evaluation committee consists of Defense Department missile czar Wm. H. Holaday, AF ARDC Ballistic Missile Division chief, Maj. Gen. Bernard A. Schriever, and Maj. Gen. John B. Medaris, head of Army Ballistic Missile Agency. The latter two officers and their respective panels of experts are currently studying each other's knowhow and achievements. The original date for settlement was, until recently, October 15, but a variety of factors—deteriorating interservice politics; the international need for the West to have operational ballistic weapons at the earliest possible date—have forced a decision to be made sooner. As a result, a crash program has been instituted. Congress, the Defense Department and General Schriever & Co. have paid extensive visits to ABMA in an attempt to find out just exactly what is going on in the missile field.

FACTORS AFFECTING *JUPITER-THOR* DECISION are many and sometimes conflicting. On the record to date, *Jupiter* is the superior system: it has flown its design distance three times; its guidance has demonstrated a suprisingly high degree of accuracy. Despite its troubles, AF has consistently called *Thor* a production missile and has expended considerable funds on tooling, etc. If the decision is for *Jupiter*, as it appears it must be, *Thor* production facilities can be turned over to other projects—or Douglas might be appointed "second source," though it's doubtful if the volume of the order would justify this.

ONE OR THE OTHER MUST BE CHOSEN. This is certain. A combination is impracticable. The only part of the two systems that is common to both is the NAA liquid-propellant motor, and in each case this is completely trouble-free. Aerodynamic configuration, guidance, control, warhead, etc., are all different for *Thor* and *Jupiter*. A missile is a highly integrated system. This comes only with the expenditure of money and time. Starting anew, for example, to work *Jupiter* guidance in with *Thor's* control system, would dangerously delay operational IRBM.

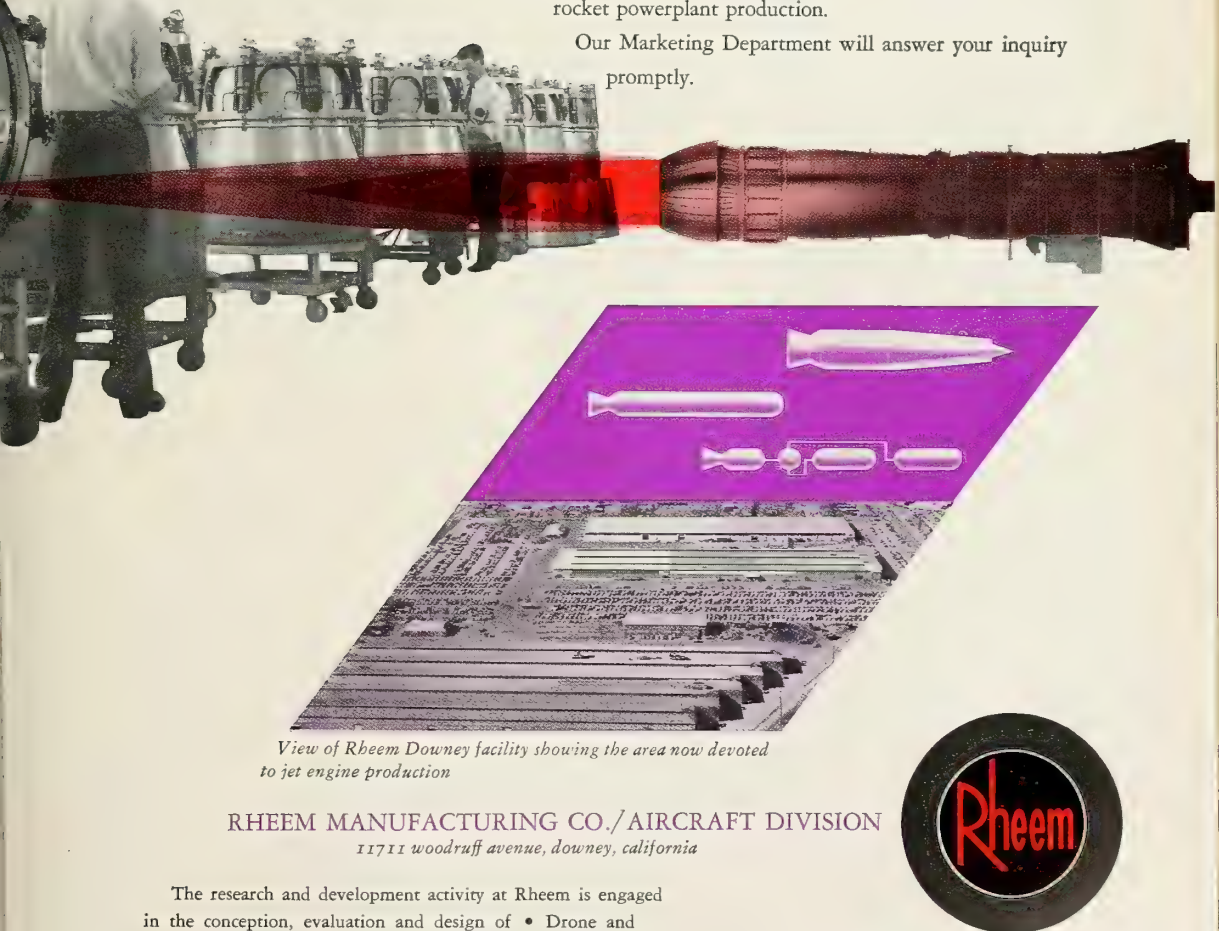
THE NOD WILL GO TO *JUPITER*. At least this will be the case for this country's earliest IRBM. Later versions may combine both *Thor* and *Jupiter*, but any effort to combine the two systems now will only serve to delay the time when this country will have an IRBM by many months, if not years. Whichever way the decision goes, somebody will be embarrassed—either AF or Army. The basic national need for a usable weapon in this category is so great that politics, etc., will be laid aside.

BRITAIN WILL BUILD ITS OWN LONG-RANGE MISSILES. Tip-off is licensing agreement between NAA Rocketdyne and Rolls-Royce for RR to build large liquid-propellant engines. In fact, this could have been guessed. Britain cannot afford (politically) not to build big weapons.

CLEAN-UP OF CONTRACT PROCEDURES continues as Congress questions recent military service practice of terminating contracts "at the convenience of the contracting authority." Between Jan. 1, 1954 and April 30, 1956, of the 13,711 contracts terminated, 91 per cent were terminated under the convenience authority. Of the 13,711 contracts (worth nearly $4 billion) terminated, 12,502 employed the special authority. House Military Operations Subcommittee considers that this special termination authority has been overused by Army, Navy and Air Force.

PROGRESS PAYMENT ALLOWANCES HAVE BEEN CUT on all price-type contracts. These are being cut back in an effort to minimize the effects of military spending program reductions. Defense Department directive, detailing new formulas for progress payments, is No. 7800.5. It applies primarily to new contracts, though those in force now with optional clauses will be adjusted downward accordingly.

HOT COMPONENTS



for the powerplant industry

The Aircraft Division of Rheem is currently delivering production quantities of high temperature non-rotating components for many of the most recent jet engines.

Rheem's production capabilities are now being applied to the requirements of the powerplant industry... on the specialized problems associated with the fabrication and assembly of heat resistant materials.

Rheem's experience and facilities are available for application to new challenges in air breathing and rocket powerplant production.

Our Marketing Department will answer your inquiry promptly.

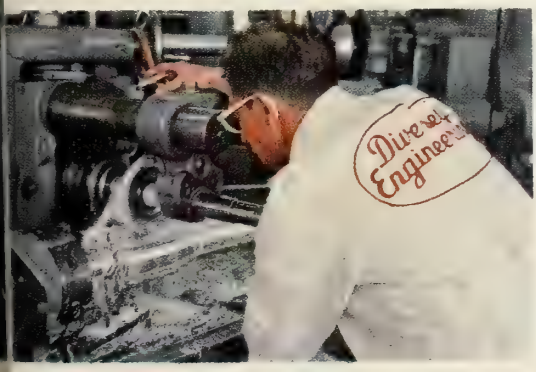
Machining for Missiles



The greatest single need in missiles today is producibility, repetitive-but-reliable mass production of complex close-tolerance parts. A curse and a beauty of missiles and rockets is that they are not like airplanes—a curse because we now try to build them as though they were; a beauty because, we start to realize, we don't have to. Once the first design tangles are out of the way, missiles are susceptible to the same kind of production knowhow that works so well for highly competitive consumer products. This means: The expensive, exotic, sophisticated, often preposterous missile of today is subject to cost-cutting techniques never yet available to military aircraft. It takes some getting used to, but is beginning to be applied at the bits, parts and pieces level. And what the vendors and subcontractors have begun will become common to the whole industry—for they now figure on trying for some missile systems contracts

To the left, J. H. Kauffmann, President, Diversey Engineering Company, Franklin Park, Ill., admires the dye mold for a HAWK nose cone. . . . Beyond, a solid propellant rocket nozzle is checked for surface finish—16 microinches on production items is not unusual, attained in the regular machining operation without additional polishing. . . . The smaller dye mold in this series is for the SPARROW. Immediately below, the core mold for a solid propellant rocket motor requires intricate close-tolerance tapered contours . . . while above right, Monarch air tracer lathes, a mainstay of missile metal machining, cut missile adapter rings out of solid stock. Plus-or-minus one thousandth of an inch over a 24 inch diameter, is a standard missile tolerance. Missile metals range through the temperature series from aluminum to molybdenum. Repetitive near-automatic machining is a must. New tools are being devised, as often by the machine tool user as by the manufacturer. Missile machining is highly competitive. New methods are being perfected, and certain aspects of missile production begin to take on the air of a Detroit assembly line. Of the 15 missile machining companies in the country, Diversey, which also does rocket motor assembly, is largest.

NO PLACE TO HIDE

They can run but they can't hide from this ***ARMA*** Defensive System — the guardian of the B-52.

Called the MD-9, this weapon is just one of ***ARMA'S*** "sixth sense" systems . . . systems whose "sensing" abilities derive from the integrated use of gyroscopics, radar, optics, computing, pneumatics and hydraulics.

And these "sixth sense" projects provide exciting new areas for engineers. ***ARMA*** . . . Garden City, N. Y.

Astrionics

By Henry P. Steier

The Army has done it again! Recent "mail delivery" flight of *Jupiter* missile points up delivery accuracies achievable with Army's basic guidance system technical philosophy. The flight "delivered" a letter to Maj. Gen. Medaris, Commander, Army Ballistic Missile Agency.

After a flight to a couple of hundred miles altitude, and covering a range of about 1200 miles, the missile reportedly fell within a predicted 400-yard circle and the letter was easily recovered.

Not bad! And, it brings to mind the undercover war that has been waged between Army and Air Force guidance experts on relative merits of air-bearing versus hermetic-integrating gyros (liquid-floated to cause rotor weightlessness) as sensing elements in inertial guidance systems for Army's *Redstone, Jupiter* missiles and AF's *Atlas, Thor, Titan,* missiles.

Army's marriage to air-bearing gyros probably reflects strong influence of gyro philosophy held by German scientists in Army's employ. The philosophy began with design of German V2 during World War II. V2 used air-bearing gyros. Basic idea of using air for a bearing is to reduce friction at the bearings supporting the gyro rotor and thus remove error induced by unwanted friction torque.

On AF side Ramo-Wooldridge Corp. is reportedly pushing use of HIGs as the answer. However, rumors state R-W believes HIG gyros supplied by Minneapolis-Honeywell are "too good". They *are* good, and apparently are the mainstay of inertial navigation systems for aircraft where problems are somewhat different than in missiles.

Some indication of reliance the AF is placing on its gyro philosophy is indicated by recent reports of a switch from radio-inertial to pure inertial for the *Atlas. Titan* reportedly also uses pure inertial, although the *Thor* is radio-inertial.

Attack on the basic parameters of bearing friction was begun by Sir Isaac Newton near the end of the 17th Century. Newton learned some basic facts when he experimented with resistance to motion of two concentric cylinders turned relative to each other while submerged in a liquid. He observed that for a constant temperature, the frictional force was proportional to the speed of rotation and to the swept area, and inversely proportional to the radial clearance between the cylinders, providing this clearance was small. The equation Newton got from this theory was demonstrated to be accurate when applied to air-lubricated bearings by Albert Kingsbury, an American, in 1897.

Surprisingly, top-quality air-lubricated bearings can be purchased at the local drug store. Dry hypodermic syringes are excellent journal bearings that run very well with air as a lubricant under ordinary hydrodynamic conditions. When air is introduced into bearings hydrostatically at elevated pressures, load carrying ability is very good.

Some basic papers on air and water bearings in the 1941-1945 period work of the Institute for Technical Physics at the Technical Higher Institute, Darmstadt, Germany indicate intense German interest in such bearings for gyros during the war. These probably influenced V2 design and seem to be still influencing U.S. designs. Sperry-Gyroscope was a major early producer of air-bearing gyros in the U.S. and still produces them through its Ford Instrument Co. division for the *Jupiter*. Just recently, Sperry began production of HIG type gyros of latest design for AF navigation systems.

Whatever comes out of the "gyro-war", the Army has established a very handy standard of reference with its recent *Jupiter* flight and the results should be interesting to watch.

Missile Miscellany

How miscellaneous can you get! Defense Department learns of Army's year-old ability to launch a satellite with off-the-shelf hardware and issues direct order to ABMA's Gen. J. B. Medaris not to do so; dispatches auditors to Huntsville to see how Army missile money's being spent—and likes $29-million Vanguard to an admitted $110 million. AF telephones in cancellation of Navaho—cost to date, $690 million—and "dead" bird makes perfect Mach 2-plus flight. ARDC officially defines space flight as dirty word; orders its Office of Scientific Research to deny any-and-all contemplation of moon rockets—then puts on gala show for AF Ass'n meeting that's all space flight, including spacemen spielers in passionate pink uniforms and star-gazing quotes galore from AF generals. And now a $139-million production contract for Bomarc even though missile's yet to meet design requirements for operational reliability at range. Your turn, Mr. McElroy!

And who popped up the other day but a friend asking m/r: "Why don't you glaze your articles a little bit, like other magazines do?" In reply: We roam, report and reflect and where the chips fall, we leave them. m/r's life and primary interest is the missile industry and for this reason we must serve as conscience, executioner and number one salesman. Footsy, glazing and other connivery remain the privilege of the old, established and subsidized. We don't want missile business to rust prematurely . . .

CX—This page heard wrong (it's human): Army, not AF, worked out anti-slosh devices that took teeter out of Jupiter. Even so, AF argues any combination IRBM be called Thorpiter instead of Thupiter, as suggested, because "we think we deserve more credit . . ." And further proof that there's still humor (and hope) in the missile business, a quip from Redstone Arsenal: "Retreat, Hell! Those are our rockets."

A hint to the "Surfcasting, Long-Lens and Birdwatchers League" at Cape Canaveral: Thiokol's Polaris motor has been dubbed an octopus with the bends. More on propulsion: Advances in solid thrust, mass ratio and specific impulse now under static test may result in giving current Far Side configuration moon impact capability. NACA has proposed afterburning as a way to give ramjets thrust control over a wider range. Despite all the talk, zip fueled ramjets still haven't been flown because of lack of knowledge because of lack of boranes. New production methods should hike supply; cut costs.

Any industry is made up of companies, and there, trends reveal the future: A hotshot management team's being dispatched from Ford Aircraft Engine Division to already competent Aeronutronics. And just a few miles south, NAA's de-Navahoed Missile Systems Division wins AF long-range WS-131B air-to-surface missile contract, but continues to peptalk its salesmen on fact that Army and Navy also have some missile money to spend. Meanwhile, OMAR the first of the missile "groups" lingers in a kind of suspended animation. And from an old Chinese rocketeer, vendors will become primes if they're careful and sharp; primes will become vendors if they're not. More philosophy: Reliability and producibility go hand in hand. They do. They do.

For a Full House we now have several companies working on an anti-anti-missile-missile missile . . . hyper-muzzle velocity bullets may be the best answer yet for bomber anti-missile defense . . . Polaris won't get Bob Truax (or vice-versa) after all—Gen. Schriever talked Navy into extending his AF ballistic missile tour . . . Motorola's tube rejection rate in Terrier black box assembly line was ½% compared to 10% national average and has achieved Ivory soap in-flight reliability for its units . . . careful tests by some guidance system manufacturers show contract specifications may exceed actual operational environments by 1000%—know what this costs? . . .

want a better end for your ideas?

"They spend a fortune to find us—and then relegate us to meaningless detail." Familiar? Too familiar—but these are words you'll never hear at Firestone's Guided Missile Division. Your ideas, your talent, your genius-in-the-making won't end up in routine rehashing of run-of the-treadmill rudiments.

Why? Part of the answer lies in Firestone's small-project, select-team approach to large-scale engineering problems. Part lies in over half a century of intelligent and successful administration of scientific efforts.

The large-scale engineering problem in our Los Angeles headquarters is the continuing development program for the Army's Corporal. In Monterey—Carmel-by-the-Sea, our new Engineering Lab is busy plotting new directions for guided missiles. And while you're making the most of your professional ability, your family (and you) will fall in love with the Golden State of living!

Next logical step after Vanguard?

THE FAR SIDE OF THE MOON

We don't know what we'll find there—it's the side of the moon we never see.

Yet, after Project Vanguard, a flight to the moon—and a look at its far side—would be the next logical step in our penetration of outer space.

To make this step, we must solve the problem of guidance: How do you direct a rocket out and around the moon and then back to earth?

The most promising method to date would include the use of inertial guidance systems such as Honeywell has helped pioneer and develop.

Honeywell's inertial guidance systems consist of ultra-precise gyros, accelerometers, computers and associated electronics that enable a missile to know where it is and how to reach its destination by "remembering" where it started from and where it wants to go. It provides guidance far beyond the reach of radio or radar.

Pioneering in the research, design and production of airborne controls has given Honeywell Aero the advanced technical competence you can rely upon in the solution of your airborne control problems. Contact Minneapolis-Honeywell, Aeronautical Division, 2600 Ridgway Road, Minneapolis 13, Minnesota for valuable assistance—from original planning to final production.

Actual photo of the Honeywell space reference system designed for Project Vanguard. This Honeywell inertial-type guidance system will guide stages one and two of the Martin-designed earth satellite launching vehicles. Third stages will then cut loose to position satellites in their orbits.

Honeywell

H HONEYWELL *Aeronautical Division*

EDISON'S resistance temperature detectors eliminate signal amplification

MODEL 235N90-35
Designed for fast response and high resistance to the corrosive effects of rocket fuels used in guided missiles.
SPECIFICATIONS:
Stem-sensitive.
Useable temperature range —70° to +200°C.
Exponential time constant in agitated waterbath 0.8 second. Maximum hydrostatic pressure on stem: 750 psi at 100°C.
Basic resistance at 0°C = 90 ohms.
Hermetically sealed.

MODEL 242P
This Detector can be operated in live steam or high temperature atmospheres up to 1300°F.
SPECIFICATIONS:
Stem-sensitive.
Useable temperature range —70° to +750°C.
Maximum hydrostatic pressure on stem: 300 psi at 750°C.
Basic resistance at 0°C = 100 ohms.
Hermetically sealed.

MODEL 230N
A general purpose Detector for temperature measurement and control in industrial processes.
SPECIFICATIONS:
Stem-sensitive.
Basic resistance at 0°C = 120 ohms.
Hermetically sealed.

MODEL 166NC
Element is concentrated in tip for sensitivity to surface temperatures in motor bearings, etc.
SPECIFICATIONS:
Tip-sensitive.
Useable temperature range —70° to +300°C.
Basic resistance at 0°C = 120 ohms.

FROM THE MONITORING OF VOLATILE HYDROGEN PEROXIDE . . . TO THE CONTROL OF CRITICAL MOTOR SLEEVE BEARING TEMPERATURES

Edison, leader in the research and development of temperature control systems, applies the principle of the simplified bridge circuit. Resistance Temperature Detectors form one arm of this bridge to eliminate the need for signal amplification. These Detectors are hermetically sealed in a corrosion-resistant steel well and terminate in leads of ordinary copper wiring. Hermetically sealed detectors in normal service can be expected to show less than 0.05% resistance calibration over a five year period.

Resistance tolerance of ± 0.5% for stem-sensitive detectors and ± 1.0% for tip-sensitive detectors are inherent in production.

Edison's exceptional production facilities and technique of hermetically sealing the element give these detectors exceptionally long life and stability. For this reason they are specified for use in corrosive atmospheres of the type found in exotic fuels used to propel guided missiles, chemical processes and in nuclear reactors.

Because of its high accuracy and exceptional stability, the Resistance Temperature Detector is used as a measurement standard for part of the international temperature scale. Response time as high as 0.25 seconds has been achieved.

Edison's Detectors may have applications in your individual control system. Call, or write today for Brochure No. 3016D for additional details.

INDUSTRY SPOTLIGHT

By Norman L. Baker

Boron Plays Lead Role in HEF Development

Niagara Falls, N. Y.—Olin athieson predicts that the production high energy fuels, demanding boron mpounds as the basic ingredient, will ach the $1-billion figure within ten ars. For a field in such short exist- ice, its present rate of growth is markable. This expensive infant, ruggling for recognition in an in- istry dominated exclusively by hydro- rbons, is emphasizing "performance fore cost." Officials in the industry e very optimistic about its future.

t Age Provides Impetus

The emphasis on boron was a rect outgrowth of the search for an eal fuel for high performance jet gines. Requirements for this ideal el are:

1) high energy content per unit eight
2) high energy content per unit lume
3) easy handling
4) low in cost

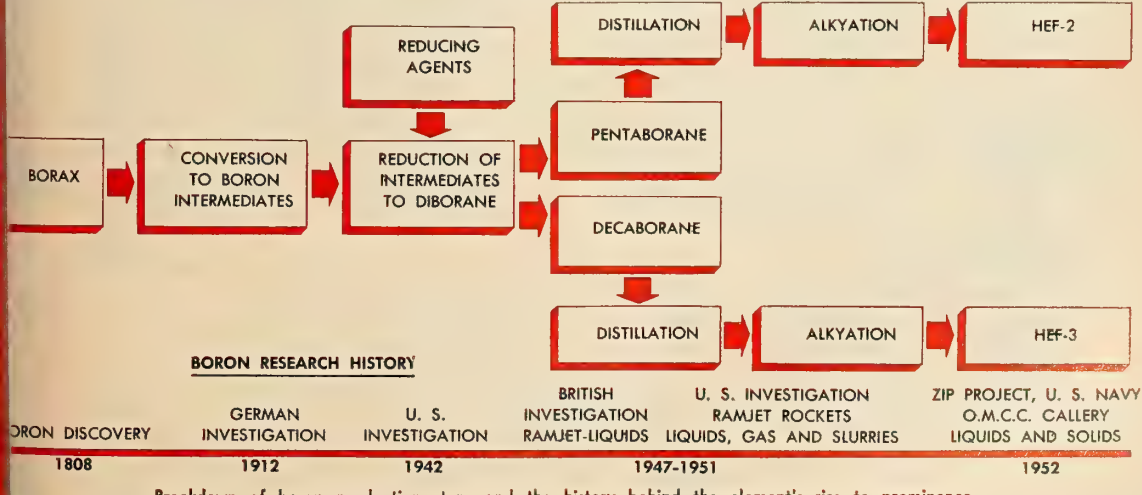
The long standing hydrocarbons, rfoming efficiently as aviation fuels, uld not meet all these requirements. ie HEFs that have been developed d recently placed in limited produc- n will encompass all these require- ents. The most important require- ment is the BTU/lb. value, which is the characteristic that separates the high energy fuels from the hydrocarbons. Aviation gasolines have a heating value of about 18,500 BTU/lb. while HEFs are in the range of 25,000 BTU/lb. It has long been known that hydrogen-carrier compounds possessed the highest heats of combustion. Liquid hydrogen, when considered for its heat content, would be an ideal fuel. This element was quickly eliminated due to its low density and the extreme difficulty in handling. Beryllium, the next element to be considered, has a heat content of 29,000 BTU/lb. This element was not very promising because it is rare and expensive to process.

Boron, with 26,000 BTU/lb., presented a much different picture. Here was an element that was very plentiful and would fit into a mass production processing operation. This nonmetallic element exists only in combination with other elements. Boron, next to lithium, is the lightest element to combine with hydrogen.

Borax Basic Ingredient

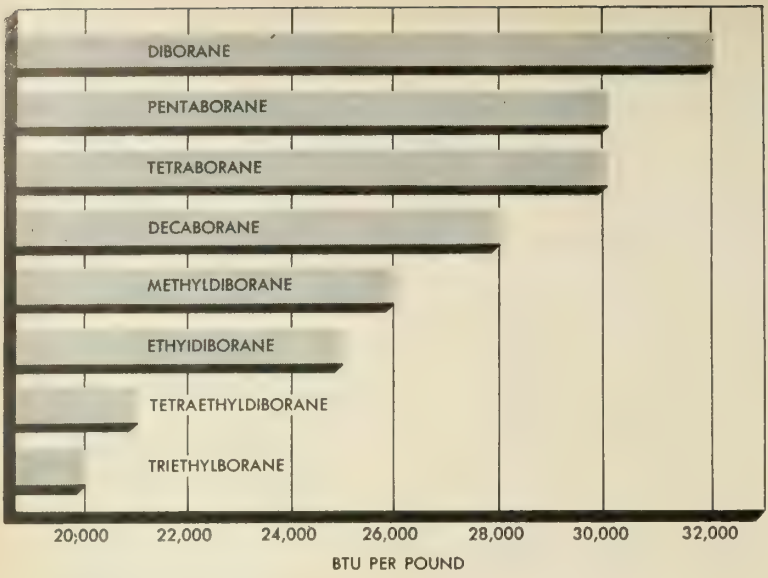
The principal source of boron was available in unlimited quantities in the compound borax ($Na_2B_4O_7$). For many years a household item, this crystalline salt is mined extensively in the U.S. and South America. The use of borax for production of HEF commands only a small percentage of the borax industry but in a few years this market could easily be the most important.

A Big Three in borax production supply the free world's needs:



U.S. Borax and Chemical Corp. (also Pacific Coast Borax): Supplies 70% of domestic borax production. World's largest mines at Boron, Calif., contain finest deposits of boron compounds. Originally underground, mines are now open pit.

American Potash and Chemical Corp.: Supplies 20% of domestic borax production. Borax is recovered from brine deposits of Searles Lake near Death Valley.



Stauffer Chemical Corp., West End Chemical Div.: Supplies 10% of borax requirements. Recovers borax from brine deposits of Searles Lake.

Intermediates Expensive

Once the basic boron-carrier compound had been found, the next step was to "alloy" the boron with hydrogen. In this way the optimum

Breakdown of boron production steps and the history behind the element's rise to prominence.

Comparison of heat output from various types of borane used as rocket propellants.

could be obtained in heat content, handling characteristics and manufacturing economy. The borax was first converted to a useful boron compound known as an intermediate. The preparation of the intermediates apparently is the more complex and expensive of the operations.

HEF producers are currently using outside purchased intermediates. Boron trifluoride, boron tribromide, and boron trichloride are the three outstanding intermediates now being used for HEF production. Leaders in the production of intermediates a Stauffer, Metal Hydrides, Americ Potash, Chemecon, Delta, Gener Harshaw, K & K Labs., Ohio Chen cal, and Pilot Engineering.

Propellant Processing

The intermediate is reduced either sodium borohydride or lithiu hydride to obtain diborane, the k borane propellant. Diborane, a gas, unsuitable as a propellant due to s bility and logistical involvements.

The processing from this stage can follow more than one route. the application of heat the dibora can be converted to either pentabora or decaborane. When deriving pen borane it first goes to the unstab form (B_5H_{11}) which then reverts the stable pentaborane (B_5H_9).

Although pentaborane has reasc able physical properties (BP 140° sp. gr. 0.61) it is possible that it w be limited to moderate speed rang due to aerodynamic heating. The so state decaborane ($B_{10}H_{14}$), on the oth hand, has a melting point of 211 and a boiling point of 415°F. The or problem here is to get it into suspe sion in the fuel.

Performance figures released Olin Mathieson, indicating a reducti of 10-20% in aircraft or missile ran

SDD needs an aeronautical engineer who might aptly be described as a specialist in the element of choice. He will be required to evaluate equipment and equipment systems for purposes of incorporation into a major nation-wide system. The position requires general familiarity with a wide range of technical subjects, including missiles, interceptor aircraft, and electronic systems, with recent specialization in at least one of these. The ability to think in broad concepts, while retaining mastery of subordinate but complex factors, is also necessary.

THE ELEMENT OF CHOICE

This engineer must be qualified to keep up with advancements in his field, through liaison with other departments and companies. Call collect or write for more information.

Getting Talos Off to a Good Start

DESIGN
ENGINEERING
DEVELOPMENT
PRODUCTION

For its initial flight, the XX*-ton Talos ram-jet missile is pushed skyward by a powerful booster rocket. In a split second from launching, internal pressures are up to XXXX* psi . . . nozzle temperatures to XXXX* F. To design and produce a unit to endure such sudden torture called for an unusual combination of specialized engineering and fabricating skills. A major responsibility for the Talos rocket case was assigned to The M. W. Kellogg Company

Since 1951, M. W. Kellogg has been closely associated with the development and production of propulsion units for a wide range of missiles. Kellogg's most recent contribution is the development of reinforced plastic for rocket cases, using a unique filament winding method which produces structures of unparalleled accuracy and light weight.

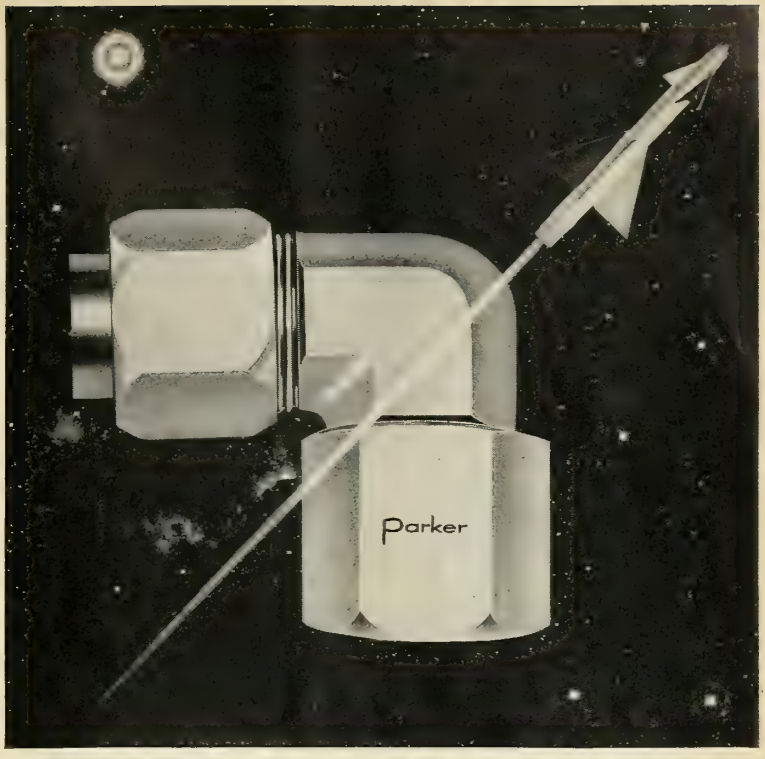
when using HEF instead of pentaborane, could mean that their HEF is an alkylated pentaborane or decoborane. The addition of an ethyl alkyl group to the propellant would improve stability with the resultant loss in heat content.

OMCC identifies their borane propellants as HEF-2 and HEF-3. Informed sources refer to HEF-2 as ethyl alkylated pentaborane and HEF-3 as ethyl alkylated decaborane. Meanwhile, the successor to HEF-3 is ready to be phased into production.

Development History

The first synthesized HEF was submitted to the Air Force two years after initiation of a concentrated effort by industry research teams. Preliminary studies of boron began many years earlier.

Boron chemistry was first investigated in Germany in 1912. Early work in the boron hydrides was not followed up in this country until 1942. It was the Royal Aircraft Establishment in England which first initiated studies of boron as a propellant. The U.S. was soon experimenting with boron compounds for rocket and ramjet fuels. These experiments were extremely limited by a shortage of available materials.



Major impetus was supplied by the Navy in 1952. Research and development contracts to Callery Chemical and Olin Mathieson for Project ZIP, gave birth to the present borane propellant industry. The project was under the Navy's Bureau of Aeronautics until 1956, when it was placed under the Air Force.

The pioneer work by Callery and Olin Mathieson has given them a lead that has not been challenged to date. American Potash & Chemical Co., classed as an intermediate producer for HEF, is also turning out the decaborane propellant. AP&C's price tag of $600-800/lb. for the propellant indicates a small scale operation at the present time. Their predicted commercial price of $100/lb. will still be too high for extended USAF consideration.

Progam Expands

Olin Mathieson's $5.5-million company-owned pilot plant at Niagara Falls, N. Y., first to produce borane propellants on a semi-commercial basis, is now making deliveries to the Air Force. A $4.5 million interim plant, under construction for the Navy, will soon go into operation. Output of this plant is expected to triple present production of borane propellants. The USAF's $36-million Model City in Niagara Falls is scheduled to be completed by early 1959.

Estimates on the capacity of the

Parker Triple-lok fittings stand up under severest temperatures and stresses

Exhaustive tests by Parker and by missile builders prove that Triple-lok tube fittings stand up under the severest punishment of rocket stresses and strains, high pressures and temperatures . . . give you leakproof, dependable, *safe* connections.

Used on missiles and launching pads, Triple-lok fittings simplify construction, provide trouble-free connections, last longer. No matter how close the quarters, or how intricate the system, Triple-lok fittings are fast, easy to install.

Will even hold helium. Parker Triple-lok fittings can be furnished with specially treated flare nose surface that will trap even elusive helium, which no ordinary metal-to-metal seal can do.

The industrial standard. Triple-lok fittings come in a wide range of sizes and shapes (including *straight* threaded and *female* pipe threaded bodies). Available in type 316 stainless steel; in other alloys on special order. Warehouse stocks in all industrial centers. Ask your Parker Distributor for Triple-lok Catalog No. 4310, or write to —

Model City facility vary but most sources feel that 2-3 million lb/year is conservative. Olin Mathieson officials are quick to point out that Model City is not intended as a production facility to meet completely the needs of an Air Force traveling entirely on HEF. The "limited production" plant, with 13-14 times the present borane propellant processing capability, is expected to meet the requirements of engine development. Although present fuels are being produced solely for jet aircraft development, such as the WS-110 project, officials confirm rocket engine development work utilizing HEF. Reaction Motors is Olin Mathieson's complimentary partner in the rocket research field.

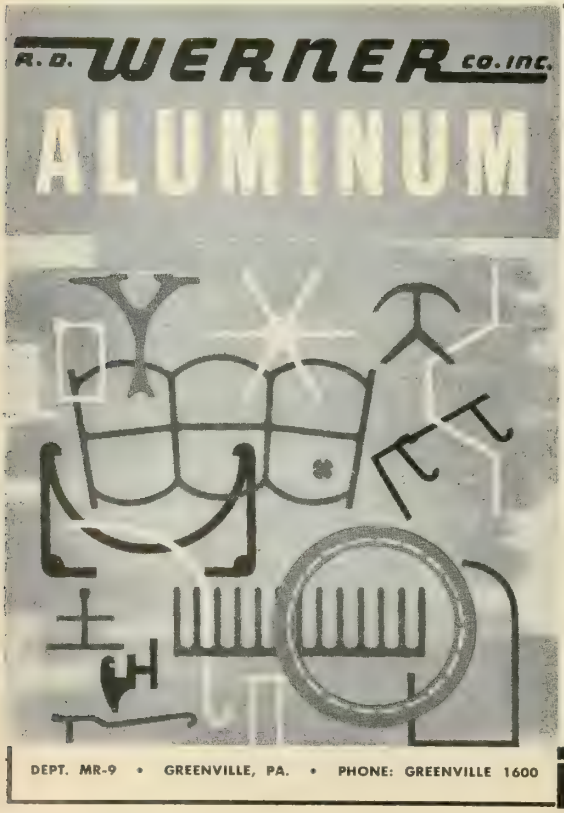
The role of HEF in the liquid propellant rocket field is questionable. This, according to officials of Reaction Motors, is the conclusion reached after many years of research. Main objection is the high weight of combustion products. Although the HEF heat of combustion is an attractive feature, the heavy combustion exhaust lowers performance until it is only slightly above that of "conventional" propellants. Added to this is the high cost, toxicity, handling and availability problems of HEF.

HEF for rockets seems destined for the solid propellant role. An indication of this is the recent Air Force contract to Olin Mathieson and Reaction Motors for development of high energy solid propellants. Reaction Motors is prime contractor with a sub-contract to OMCC. Olin Mathieson will develop the propellant at its East Alton, Ill. plant while Reaction will package and test the final product.

Callery Chemical's present HEF plant facilities expansion program is on a comparative basis with Olin Mathieson, except it is under Navy sponsorship. In addition to their headquarters and operating pilot plant at Callery, Penn., Callery is building two plants for HEF output. Largest "chemical" plant, located at Muskogee, Okla., will be a $38-million Navy facility. Plant at Lawrence, Kan. will be a $5-million company financed project. Olin Mathieson's plants will devote entire output to HEF while Callery's production will be more diversified and flexible.

In 1952, when the Navy was looking around for takers of the ZIP project the petroleum people apparently were not interested. Perhaps a gauge to the future of the boron industry has been exhibited by the recent Gulf Oil Co. merger with Callery Chemical.

One thing is certain. The present cost of HEF is apparently much too high. Olin Mathieson, although not quoting exact figures, stated that their present fuel is priced considerably less than $30/lb.



OMCC's goal of $1/lb within ten years, where reducing agent is recovered and recycled, should place borane propellants firmly and permanently in the propellant picture. A stable continued growth of boron depends upon the extent and urgency of the military's need for a better propellant.

Era Engineering Winds Up Van Test

Era Engineering, Inc., Santa Monica, Calif., has completed initial field tests on an instrumentation van constructed for Grand Central Rocket Co., Mentone, Calif.

Especially designed for use at remote static rocket motor firing areas, the unit contains electronic recording and pickup instruments, a master fire control panel, and can act as a central communication center for the test area.

The master fire control panel, a feature of the van, was developed by Era expressly for static testing of rocket motors. The panel functions to turn on recorders, cameras, calibration

signals, the rocket motor, and then to successively turn off the same pieces of equipment.

If the test should be interrupted for any reason, it is possible to stop the sequence operation and to automatically instigate calibration checks before turning off the equipment.

The panel is also designed so that the switching schedule can be revised in the field in just a few minutes.

RMI Completes Huge Test Stand

Reaction Motors Inc. has completed, and is operating, a huge new rocket engine test stand at its Lake Denmark, N.J. facility. The stand is claimed to be the largest of its kind in the country and is believed to be the only stand in the world capable of testing engines of over one-million-pounds thrust in any flight attitude.

The stand uses retractable roof and front and side curtains, representing the latest design for test purposes. The stand was designed by RMI engineers and incorporates test and measurements equipment and closed circuit television. The control room, containing instrumentation, recording and monitoring equipment, is located several hundred feet from the test stand.

The large rotating beam, on which an entire engine assembly (including thrust chamber, pumps, regulators, tankage, propellant lines, etc.), can be mounted, is raised and lowered by a huge hydraulic cylinder.

During vertical firings, the rocket engine exhaust is deflected horizontally by a blast plate so that the energy is expended in open air. A two-stage water spray ring system has been installed between the engine nozzle and the deflector plate to cool the exhaust gases and prevent erosion.

80,000-lb. Mica Melt Announced by Synthetic

Synthetic Mica Corp. has produced the largest commercial melt of synthetic mica yet attempted. The company says it used 80,000 lbs. of raw material in the process. After approximately three weeks of cooling, the company broke up the mass of crystalline Mica and will grind or split it into usable form.

The company is conducting research toward producing larger area crystals in great volume. Crystals as large as 4" x 4" have been produced consistently.

Developments are being watched with interest by government agencies and manufacturers of high-temperature electrical and electronic equipment.

ROCKET POWER PROGRESS REPORT

Servicing Rocket Engines

Part I: Know-How

by Fred Barker

Supervisor of the Product Service Department at Reaction Motors, Inc., Mr. Barker coordinates the activities which keep rocket engines on their good behavior. A graduate of New York University, with a B.S. in M.E., he has had diverse experience in engineering—including test, manufacturing liaison and customer service liaison. Mr. Barker joined RMI in 1949.

"Know-how" in any business is the result of thorough training and experience on specific products. RMI Product Service Department personnel get a complete grounding on their products right from the development stages through field installation and operation. The know-how thus attained is turned into a direct benefit for all RMI customers.

Key service engineers and service representatives join a project during early development, work actively with Engineering, Component Development, Assembly, Test and Inspection Departments. Mock-ups are reviewed from the standpoint of service—i.e., whether proper consideration has been given installation, accessibility and serviceability of components and the overall powerplants.

When a project is ready to move into the field, these same key men act as instructors, conducting training programs to impart their accumulated knowledge to customer personnel and other service representatives. With our ROR powerplant (rocket-on-rotor for helicopters), for instance, Sikorsky, Navy and Marine Corps personnel attended training programs at RMI and in the field. Scope of these programs covered the rocket powerplant, its installation and operation in the Sikorsky HRS helicopter, and the use, transfer and storage of the hydrogen peroxide propellant. Once ROR settled into operations at the Marine Corps Air Station, Quantico, Virginia, the service representative's know-how assumed a stand-by character. Training programs were repeated or amplified only as required by personnel changes or powerplant modifications.

Safety is a major item in each RMI representative's assignment, because safe use of the powerplant and safe handling of propellants are of paramount importance. Safety is improved by service representatives through on-the-spot lectures and training programs, whereby procedures and policies are outlined and integrated into the activities routine. Again, at Quantico, an admirable safety record has been achieved and maintained in just this fashion. There, over the past few years, our service representative has assisted the Marines in safely utilizing the ROR powerplant and the hydrogen peroxide fuel for their HRS helicopters. The result is found in the simplicity of powerplant operations, peroxide handling and storage area procedures, and in the attainment of a "no personnel injured" safety record.

Obviously, know-how is of importance in a clutch situation. Wisely applied, it leads to the right decision and the proper corrective action on the scene of a problem. The recently launched Glenn L. Martin No. 13 Viking missile provides a case in point. Pre-static firing inspection revealed discrepancies in some components of our 20,000-pound thrust rocket engine. Normal field maintenance sufficed for all but one difficulty: a valve seat and poppet, scored by foreign material, required lapping to meet leakage specifications—but no lapping compound was on hand. Our service representative used common household cleanser, lapped the poppet and seat to within leakage specifications, and the program moved on with only minor delay. This difficulty remained minor only because prompt and proper handling prevented development of a major program obstacle. Immediate action was required; immediate action was taken.

In Part II, we shall examine the function of the service engineer and service representative in various areas of Product Improvement.

If you desire one or more reprints of Mr. Barker's article, or would like to receive further information about employment at RMI, write to our Information Services Coordinator, Reaction Motors, Inc., 16 Ford Road, Denville, N. J.

#1 in a series . . . on

the new science of

cable-tronics

©1957 Douglas Roesch

For a missile to realize its inherent reliability factor every system component must "be in tune." The burden of sensitive and complex electronic functions multiplies the problems. The inadequacy of conventional electric cabling, using standard jacketing concepts, is now recognized. Hence there has arisen the demand for "cable-tronics"—the new systems design concept of *true electronic cable structures* to meet specific requirements.

D.R., "cable-tronic" pioneers, are equipped to custom fabricate complete systems from cable spinning through connectors . . . molded breakouts . . . metal work . . . fasteners . . . testing and assembly to your specifications or research and design systems to meet your requirements.

Write for complete facilities brochure.
Rep inquiries invited.

Engineers, investigate your future with Douglas Roesch

Cable-Tronics • Electronics • Heavy Duty Engines • Industrial Products

Major *Bomarc* Contract Awarded Boeing

The first large production contract for the *Bomarc* surface-to-air missile has been awarded to Boeing Airplane Co. Latest contract, from fiscal 1957 funds, totals $139,315,444. Contract will support limited quantity production of the tactical area defense missiles.

The initial production contract of over $7 million, released in May of this year, covered tooling-up operations. *Bomarc* will be assembled in Seattle while the major portion of manufacturing will be handled by subcontractors.

Reports that the *Bomarc* has been plagued by design problems may be related to the recent decision to switch boost systems. Later models of the missile will employ a solid propellant booster motor in preference to the Aerojet liquid engine now being used. One outstanding design feature, apparent in the recently displayed *Bomarc* missiles, was the performance-limiting integration of the boost system to the sustainer portion. The solid propellant booster (if droppable) will undoubtedly increase the range, altitude and velocity of the missile.

Missile Spending Exceeding 1957 Estimate

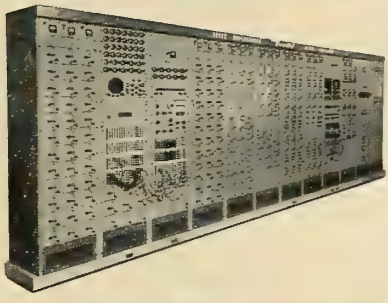
Military spending for missiles as of May 31 has surpassed the fiscal 1957 estimate. The services spent $1,868,000 for missiles—$362,995,000 more than the $1,506,000,000 planned for the period.

Service breakdown for the 11 month period and an estimate of total spending for fiscal 1957 is:

	11-Month Actual	Total 1957 Estimate
USAF	$1,261,138,000	$860,000,000
Army	374,368,000	425,000,000
Navy	233,489,000	221,000,000

Stavid Earnings Up 13%

Stavid Engineering Co. earnings for the first six months of this year showed a 13% increase over the same period in 1956. The company reported a total of $110,826 for 1957 compared to $86,524 last year.



The firm expects their present backlog of orders to increase from $11 million to $13 million by the end of the year.

Bendix flight simulators reduce the risks

The hazards of missile testing can be materially lowered when performance is checked out on-the-ground with a BENDIX 3-dimensional Flight Systems Simulator, prior to take-off. Comprised of two basic units—a flight table and an electronic analog computer—the BENDIX-built Flight Simulator will foretell complete operating programs from launching pad to target, for rockets, ballistic and guided missiles and jet aircraft. It catches bugs without expensive trial flights, materially reduces guesswork and adds a valuable safety factor at both ends of the test shot. *For complete technical data, mail the coupon.*

Double sealing . . . inorganic construction make

New 'Diamond H' Series S Relays Doubly Dependable

in dry circuits

Separately sealed coils isolated from completely inorganic switches within their hermetically sealed cases make these new "Diamond H" Series S aircraft type 4PDT relays supremely reliable in dry circuits.

Physically and electrically interchangeable with "Diamond H" Series R relays, widely used in guided missiles, computers, jet engine controls, automation control systems and similar critical applications because of their broad range of performance characteristics, Series S relays will permit intermixing of dry and wet circuits safely.

Contacts are specially processed and cleaned before assembly; subsequent contamination from gases off the coil insulation is prevented by the coil seal. The switch mechanism has been simplified and is completely inorganic to eliminate other possible causes of malfunctioning.

Standard contact ratings include 30 V., D. C.; 115 V., A. C.; 2, 5, 7-1/2 and 10 A., resistive; 2 and 5 A., inductive, with special ratings available to 350 V., D. C., 400 MA, or other combinations including very low voltages and amperages, or amperages up to 20 for short life requirements. Coils are available with resistances of 1 ohm to 50,000 ohms. Operating time of 24 V. models is 10 ms. or less; dropout less than 3 ms.

Vibration resistances range from 10-55 cycles at 1/16" double amplitude to 55-2,000 cycles at 20 "G"; operational shock resistances to 50 "G" plus, and mechanical shock resistance up to 1,000 "G". Nine standard mounting arrangements, plus a ceramic plug-in socket, are available. The unit displaces only 1.6 cubic inches, excluding terminals.

"Diamond H" engineers will be happy to work out a variation to meet your specific requirements. Tell us your needs . . . or write for bulletin on new "Diamond H" Series S relays.

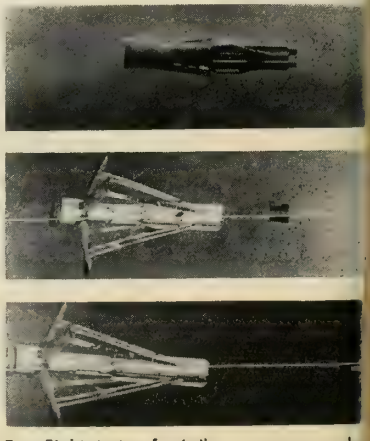
THE HART MANUFACTURING COMPANY

161 Bartholomew Avenue, Hartford, Conn.

terly C. Page, Joseph A. Waldschmitt and John Creutz was sold to James L. Hollis for an undisclosed amount. Until the time of the sale, Page had been president of Rixon.

Hollis was formerly executive vice-president and general manager of Rixon while it was a wholly-owned research and development subsidiary of PCE, and now owns all the common stock of the company. Completing the separation of the two companies, Hollis sold his stock in PCE and resigned as an officer and director.

Merger Announced By Radioplane & Northrop



Radioplane Co. has been merged into Northrop Aircraft, Inc. and will be operated as a line division of the parent company. Northrop acquired Radioplane in 1952 and had operated the Van Nuys firm as a wholly-owned subsidiary until now.

Under the realignment, Radioplane will operate under its own group of division officers and will have separate profit-and-loss responsibility. M. W. Tuttle, Radioplane vice-president and general manager, will continue as operating head of the division.

New Firm Cleans LOX Parts

Decontamination, Inc., a new division of Consolidated American Services, Inc., has been formed in Culver City, Calif. The company is a western subcontractor engaged in cleaning liquid oxygen fuel system parts for rocket motors.

Nose Cone Model Tests

Free-flight tests of missile nose cone models are conducted by GE through use of the separation device. Fired from a five-inch gun, the device extends flaps into the air stream, allowing the nose cone model to continue in free flight. This same principle may be applied to large-scale free flight.

Reaction Develops Liquid Package Unit

MISSLES AND ROCKETS has learned reliably that Reaction Motors Inc. has developed a "package" liquid propellant rocket system. The Navy has expressed considerable interest in the system as a competitor for solid propellant systems.

Essentially, the system will include propellant tanks, pressure system and rocket engine. Operation of the unit will be the ultimate in simplicity. Components common to the present complex liquid systems have been eliminated. There will be no hydraulic lines, pumps, turbos, or valves. A simple flow actuator will be the only moving part. Propellants are hypergolic, eliminating the need for an ignition system.

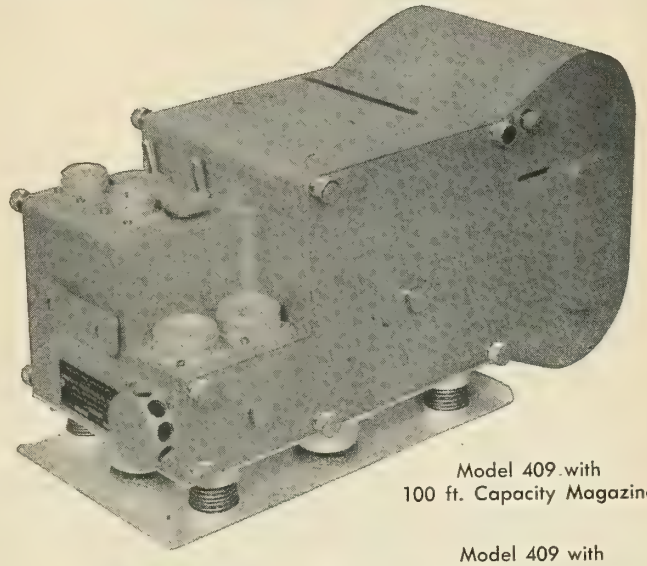
Major feature of the system is its capability to provide a constant total impulse. Other features include safe handling characteristics, cost competitive with solid propellant systems and a long storage life. In addition the missile design engineer has the option of incorporating the power package either as a fixed or replaceable item.

Reaction Motors initiated the project in 1952. As far as is known RMI is the only company working on this type of project. Apparently the Navy's interest in the program has supplied the necessary incentive for RMI to continue development. Units developing up to 10,000 lbs. thrust have been test fired while a high thrust *Polaris*-type missile system is within the present range of development feasibility studies.

Martin Employes Plan Space Vehicle

A manned space vehicle is being planned by the members of the Martin Astronomical Society. Mainly an educational program, the project is a feasibility study which is expected to involve "some of the engineering areas which will be coming to the fore in this industry during the next 15 years."

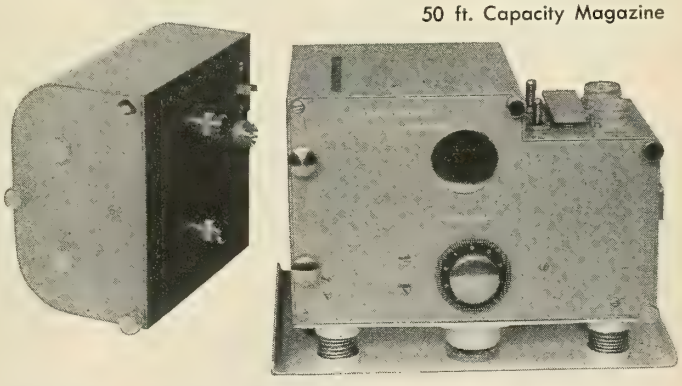
The society is composed of Martin personnel who devote their own time to a variety of after-hours programs. Eventually, it is planned to extend the membership beyond company employes.



New Field Office For Lord Mfg. Co.

Lord Manufacturing Co. has opened a new field office in Kansas City, Mo., to provide sales and engineering service on vibration and shock control problems.

Century MODEL 409



RECORDING OSCILLOGRAPH

FOR VIBRATION, TEMPERATURE, STRESS, STRAIN RECORDING

Model 409 with
100 ft. Capacity Magazine

Model 409 with
50 ft. Capacity Magazine

The Century Model 409 Oscillograph was designed for operation under the most adverse conditions and more especially, where space and weight considerations are limited.

This Oscillograph is one of the smallest and most compact units available on the present market, yet it incorporates many features found in larger oscillographs, such as trace identification, trace viewing, continuously variable paper speeds and others. The Model 409 Oscillograph has been tested and proven to record faithfully during accelerations in excess of 20 g's. This makes it especially desirable for uses such as missile launching, parachute seat ejection, fighter aircraft and torpedo studies.

GE Says Transistor Sales Might Hit $1 Billion

A General Electric executive has predicted that annual sales of transistors and other semi-conductors could reach $1 billion within the next ten years.

James H. Sweeney, manager of marketing for GE's semi-conductor products department, said that sales of transistors and similar components have risen so fast in the last few years that they have continually outstripped even the most optimistic market projections.

Sweeney noted that the main reason for the great increase in semi-conductor use is the military application of the component. Nevertheless, the GE executive ruled out any complete replacement of electron tubes by transistors, pointing out that electron tubes, transistors and other semi-conductors would probably work side by side in many future pieces of equipment.

Marquardt Delivers First Production Ramjet

Marquardt Aircraft Co., Ogden, Utah, has delivered the first production ramjet for the *Bomarc* missile. Described by the Air Force as the first ramjet engine to be manufactured with production tooling, its delivery was made one month ahead of schedule.

The *Bomarc* uses two of the 28 in. engines to propel the missile to a velocity in excess of Mach 2. Ignition velocity is supplied by an Aerojet liquid propellant rocket engine.

Marquardt has received an additional $12 million Air Force contract for continued production of the *Bomarc* engines. This brings total contract value for the Marquardt Ogden plant to $30 million.

General Dynamics Sales Increase 75% Over 1956

Net sales of General Dynamics Corp. during the first six months of 1957 showed a 75% increase over sales in the same period last year, going from $414,443,947 in the first half of 1956 to $726,081,499 this year.

General Dynamics, which topped the billion-dollar sales mark for the first time in 1956, reported its estimated backlog of unfilled orders as of June 30, at $1,989,000,000. In addition, about $654,000,000 in contracts were under negotiation as of June 30. General Dynamics expects that net sales and net earnings for the entire year of 1957 will substantially exceed those of the record year 1956.

The directors of General Dynamics and the Liquid Carbonic Corp. approved in principle a transaction in which Liquid Carbonic would become a division of General Dynamics. A company spokesman described the chemical field as a "most logical" extension of Dynamic's present activities.

American Lithium Given Study Contract

The American Lithium Institute has been awarded a contract by the Materials Laboratory of ARDC to investigate, analyze and consolidate detailed data on the physical, mechanical and chemical properties of lithium and its compounds.

Martin Sales Top $209 Million

The Martin Co. has reported a six month sales figure of over $209 million for the period ending June 30, showing a considerable increase over the total $138 million in sales during the same six-month period of 1956.

Matador Contract Awarded

Siegler Corp. has received a $1.5-million order for miniaturized magnetic autopilot amplifiers to be used on late-model *Matadors*. The Martin Co. placed the order with Siegler's Hallamore Electronics Div.

Borg-Warner Corp. Opens New Test Lab

Borg-Warner Corp. has placed its new electronic performance and environmental test laboratory into operation at Santa Ana, Calif. The lab will be used to provide environmental conditions for the critical operating examination of electronic and electro-mechanical devices and complete systems.

The new lab includes equipment capable of simulating environmental conditions of 150,000 feet in two minutes, with temperature maintained throughout the range of −135°F to 375°F, 70 g peak vibration from 5 to 2000 cps, and shock tests of 18,000 force lbs. with any desired wave form.

Computer Plant Expanded By Bendix

Computer Division of Bendix Corp. has doubled the size of its manufacturing facilities. The expansion is expected to enable the firm to produce 100 more machines annually.

Cylinder Contracts Awarded Weatherhead

Weatherhead Co. has been awarded two contracts by Consolidated Western division of U.S. Steel for manufacture of missile cylinders. The two contracts, calling for expenditures of over $547,000, are for launching-rail decelerator cylinders and launcher-down latch hydraulic cylinders, to be installed on *Nike-Hercules* launchers. Weatherhead also manufactures accumulators, hydraulic and fluid system components.

Aeroquip Corp. To Produce LP Hose

Aeroquip Corp. has been granted production and sales rights by the Weatherhead Co. for a new permanent type of fitting for hose connections. (See New Missile Products.) The royalty-paying agreement was concluded at the same time as an agreement allowing Weatherhead to produce and sell the "super gem" reusable type teflon hose fitting.

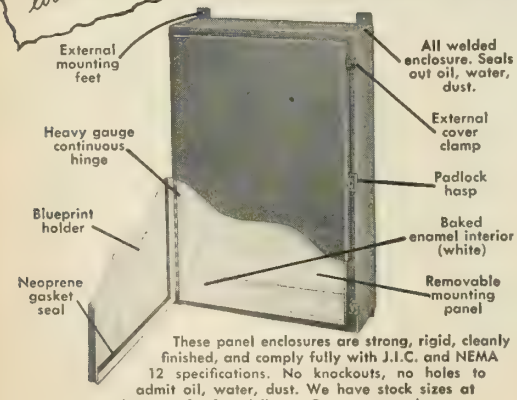
Los Angeles Plant Slated for Technicraft

Technicraft Laboratories Inc. has purchased a ten acre industrial site in the Los Angeles area and plans to begin construction immediately. The company expects the first production shipments to be made from the new plant in January 1958.

RMI Apprentice School Ups Enrollment

Reaction Motors, Inc. has expanded its machinist apprentice program enrollment from the 20 original students to 33 in the class entering last July. The four-year course in extreme-precision machine skills is expected to supply RMI with ". . . highly skilled shop labor, which is just as scarce as—and just as important as—engineering personnel."

The program, which was initiated in July 1956, provides for about 8000 hours of training, of which 6800 hours are on-the-job training and 1200 hours are related classroom instruction. RMI accepts applicants on a competitive basis from outside candidates or from within the company.



After entering the program, students are expected to turn out work that is equal or superior to work of journeymen. Course work is graduated instruction of increasing difficulty.

Although students have no obligation to RMI after graduation, the company expects to retain enough graduates to make the program a worthy one. After receiving certification of Class A Machinist, students may earn an experimental machinist's rating with an additional 9 to 15 months experience.

IBM Computer Aids *Titan* Design

The Martin Co. recently demonstrated its newly-installed IBM 704 computer which will aid in design of the *Titan*. The unit is the same as that installed in the *Vanguard* computing center.

The company's computer, most advanced of the high-speed electronic computers developed by IBM, is not a single-unit machine but a group of electrically-connected units.

Talos "Automat" System To be Developed by GE

General Electric Co. has been awarded a $5-million contract for development of a shipboard handling and launching system for the *Talos* SAM. The "automat" system will work somewhat like "pigeonhole parking" in that the missiles weigh as much as, and are as long as, two automobiles.

The equipment must be able to automatically select whichever type of missile the fire control officer chooses by pushbutton, and deliver it rapidly to the launching station.

The equipment's control system is more complex than that used in area telephone switchboard systems because not only must the system remember which missile is in what rack, but must also remember any changes in the racks themselves.

This is GE's first contract for missile handling systems. The final product is expected to weigh more than 350 tons and require space enough to hold ten freight cars. The first naval vessel to carry the new system will be the cruiser *USS Galveston*. Planned operational date for the ship is 1958.

Narmco Builds New R&D Center

Narmco, Inc. has begun construction on the first phase of a million dollar industrial research and development center in San Diego. Completion of the facility is expected by December, and it will be utilized for work on structural adhesives, reinforced plastics and sandwich-type structures.

Convair Expands European Sales Force

Convair Division of General Dynamics Corp. will expand its European sales office in Geneva, Switzerland. The office will be managed by George C. Prill.

Chance Vought Sales Rise Sharply

Chance Vought Aircraft, Inc. has reported sales of aircraft, missiles, parts and services aggregating more than $86 million, compared with over $51 million in the same period of 1956.

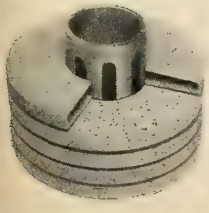
The backlog of the company's unfilled orders stood at $467 million as of June 30. In a statement to stockholders, the firm said that the present economy considerations of the government "should have no appreciable effect on current operations and management believes that its previous estimates of future business activity will not be materially affected."

McLean Names Agents

McLean Engineering Laboratories have appointed several groups of representatives to handle the McLean line of electronic cabinet cooling fans and blowers in the eastern half of the country.

Technical Instruments, Inc., of Waltham, Mass., will represent the firm in the northeastern states: The Kenneth E. Hughes Co., of Union City, N.J., will cover the middle Atlantic states; and W. A. Brown & Associates, Inc., of Indian River City, Fla., will cover the southeastern states.

NEW *Harmeco* PURAFLO FILTERS



Pneumatic Type for Compressible Gases—Pressures to 6,000 lbs.

Harmeco PURAFLO Filters are available in various case designs to suit any piping requirement for filtering helium, nitrogen and other compressible gases at porosity ratings of 2, 5, 10, 20 or 40 microns or coarser. Interchangeable multi-tube sintered stainless steel wire wound elements or strainers are optional. Case is carbon steel forging; stainless steel, monel or other materials as specified.

ELEMENT MANIFOLD PIPE ASSEMBLY

Double tapered one piece Harmeco hollow sintered bronze disc elements provide deep uniform, dependable filtration. Spacing between the discs is uniform when assemblies are stacked and sealed in ported manifold pipe. One piece element design eliminates slip fits or organic bonding materials. The double tapered, hollow disc design prevents blocking off of surface area due to possible cocking of the elements on the manifold pipe. Result: greater filtering area; uniform porosity control; clean decontaminated products.

Now... shock test with a controlled 10,000-pound thrust

The HYGE shock tester, manufactured and marketed by CEC under license from the Convair Division of General Dynamics Corporation.

Simulate actual service conditions and test shock resistance of parts and assemblies. Make *repeated* tests accurately.

The new HYGE shock tester will produce specific acceleration and/or deceleration wave forms for desired durations.

In theory, it can produce a build-up rate of 200,000 g's per second from zero to peak acceleration, with a pattern free of high-frequency transients.

HYGE can be used to develop controlled impact shocks from 2,000 to 6,000 g's—accurately.

HYGE is available in standard types, or in a "kit" of modular components. Send for Bulletin P4-70 for details.

STRUCTURAL INTEGRITY

AT ELEVATED TEMPERATURES

hi-torque® BOLTS

in *SUPERALLOYS retain their superior strength and endurance.

Research Engineers in Hi-Shear laboratories are continually engaged in the high temperature evaluation of Hi-Torque Bolts manufactured from new alloys. Extensive tests and analyses have made possible the production of Hi-Torque Bolts in a variety of superalloys for aircraft and missile applications where superior strength and endurance at elevated temperatures are essential.

The Hi-Torque design is a NAS Standard. Bolts in all diameters feature excellent "head to thread" balance, close recess tolerance control, tension allowables comparable to internal wrenching bolts without the attendant weight penalty, and a recess which may be machined into any steel or alloy. The Hi-Torque recess is of self-locking design and increased torque increases the driver locking action thereby eliminating axial loads and accidental driver slippage. This recess always provides positive removal.

* Superalloys such as A-286, Inconel X, S-816, M-352, J-1570, Inconel 700 and Haynes 25 are now available in the Hi-Torque configuration. Precipitation hardening stainless steels—AM 350, 17-4PH and AM 355—are also available.

Cooper Conducts High-Altitude Research

Cooper Development Corp. is engaged in Project Sunflare for investigation of radio propagation interference and is conducting rocket launchings from San Nicolas Island, Calif. The operational phase of the project began on July 1, to coincide with IGY, with the launching of a *Nike-Deacon* two stage rocket. The vehicle, carrying a 30 lb. instrument payload, rose to 80 miles and gathered background spectral data for about two minutes.

CDC is also using a *Nike-ASP* combination to reach altitudes of 150 miles. The initial data obtained will be used to establish baselines for signals recorded during later flights involving flares. A total of 14 rockets are scheduled to be fired during the project.

Since sunflares occur with virtually no warning, and may reach peak brilliance within 5 minutes after an alert, the rocket crews and scientists must be ready to fire at any moment. The CDC crews, alerted by participating observatories, have been getting the rockets off in about 60 seconds.

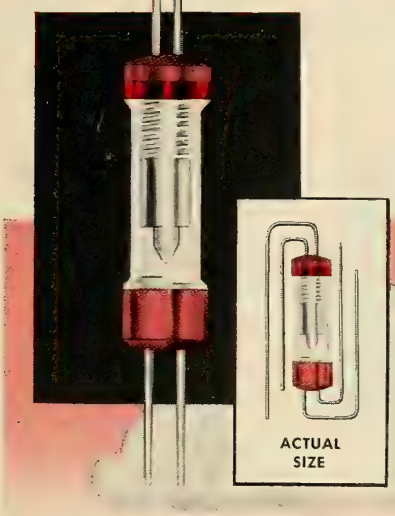
Military Products Group Set Up By Honeywell

Minneapolis-Honeywell Regulator Co. has made an administrative realignment of its divisions concerned with products for military use. The realignment, executed to meet the management, engineering and manufacturing needs of the military, is said to create "one of the largest sources in the country for research, engineering and production capability."

Packard-Bell To Develop Digital Computer

Packard-Bell Electronics has received a research and development contract from the Army for a high-speed digital computer to work in conjunction with equipment at the computation center at Redstone Arsenal. The digital simulator will compute the behavior of dynamic systems of missile airframes, inertial guidance and fire control devices.

Daystrom Ltd. Formed



Daystrom, Ltd. has been formed in Canada to handle sales, service assembly and manufacture of Daystrom electronic products. By 1960 the company expects to have a large-scale Canadian manufacturing operation.

Reliability

THERMO-ARMING RELAY

by

DIAPHLEX®
Division of
COOK ELECTRIC COMPANY
Chicago Illinois, U.S.A.

The new Diaphlex Thermo-Arming Relay is designed to close a circuit positively, and with high reliablity, with the application of 3 to 4 volts, AC or DC potential.

The Thermo-Arming Relay has been qualification tested for performance, in accordance with the specifications below, including shock, vibration, acceleration, performance at extreme and varying temperatures and pressure altitude, salt spray, humidity, and storage at varying ambient temperatures. Detailed test reports by Inland Testing Laboratories are available upon request. Cook P/N 666-1960.

Weight	Less than 0.1 ounce
Operating Temp. Range	−55° C. to +85° C.
Altitude	In excess of 75M'
Shock	250 G, 2-4 MS deceleration
Vibration	20-2000 CPS, to 40G
Acceleration	150 G
Operate Time	Less than .3 second with 3-4 VDC applied
Container	Herm. sealed in high thermal-shock resistant glass container
Trigger Ckt. Resistance	1.2 ohms minimum
Contact capacity	.5 ma. to 5.0 amperes DC
Insulation Resistance	200 Megohms minimum @ 500 VDC

bernco *test equipment serves special missile requirements*

Controls
Test Equipment
Wiring Harness
Thermocouples

A leading missile producer removed an obstacle to production, and safeguarded ultimate operation of his beam-riding missile, when he designed the special test and control unit pictured above.

By monitoring two critical voltage values, and by acting as a circuit breaker if either circuit departs from its predetermined voltage, the unit prevents damage, or complete destruction of the missile's electronic components, during tests. The result—a saving of thousands of dollars.

To build this special unit, competent engineering, skilled craftsmen and adequate facilities were necessary. The prime contractor selected BERNCO where a reputation for producing *reliable* component parts at *reasonable costs* has won the confidence of many of the nation's other leading manufacturers and government agencies.

In just a few months, the missile will be ready for operation. Meanwhile, BERNCO would like to be of service to you—if you have need for electrical, electronic or electro-mechanical component parts. An illustrated brochure describing BERNCO's services and facilities is yours for the asking. Write for your copy, now.

BERNCO ENGINEERING CORPORATION • 2322 SOUTH TIBBS AVENUE • INDIANAPOLIS 41, INDIANA

Litton Industries On Stock Exchange

Litton Industries, organized in November 1953, became one of the youngest firms to be listed on the New York Stock Exchange when its common stock was called for trading on July 30. The company's common stock has been traded on the American Exchange since September 1956.

With recent establishment of an activity in Salt Lake City, Litton now is in operation at 11 locations across the country. The firm is engaged in research, development and manufacture of advanced electronics.

American Aerophysics Adds Fiberglass Division

American Aerophysics Corp. has added a fiberglass division with facilities for development and fabrication of high-strength fiberglass-reinforced laminates for the missiles industry.

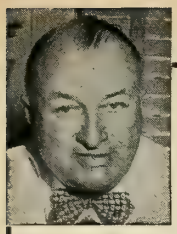
The new division will design and produce jet vanes, rocket exhaust nozzles, missile fins and control surfaces, radomes and other equipment.

Callery Chemical Moves Headquarters

Callery Chemical Co. has moved its administrative and sales offices from Callery, Penna., to Pittsburgh. The company recently established new plants at Muskogee, Okla., and Lawrence, Kansas. The Callery, Penna., facilities will remain as R&D division headquarters for the company, which manufactures boron chemical compounds and HEF for missiles.

Laminair Has New Plant

Laminair, Inc., specializing in missile structural and radio frequency fiberglass laminates, has opened its new plant in Gardenia, Calif. The new plant has complete tooling and production facilities for work in polyester, epoxy, phenolic and silicone resins.



Ryan Declares Dividend

Ryan Aeronautical Co. has declared a regular quarterly dividend of 10 cents. This will be Ryan's 28th consecutive quarterly dividend and the 48th since incorporation.

Temco Sales Up

Temco Aircraft Corp.'s sales for the first half of 1957 were at a record high level, rising 56% over a like period in 1956. Backlog of orders at the company's three plants stands at approximately $172 million.

Circle No. 90 on Subscriber Service Card.

West Coast Industry

By Fred S. Hunter

Lockheed Missile Systems division's new test facility is beginning to take shape near Santa Cruz. Only a few pre-fabricated buildings have been erected, but during the coming year more than $1 million will be spent for site improvement and, if the program is expedited, this figure may go to $2.25 million. First steel test stand is to be ready for rocket firing to begin in February. Four more stands may be erected by the end of 1958 at which time Lockheed expects to have 100 to 150 employes permanently stationed at the Santa Cruz mountain site. Four members of a small-explosive test group comprised the first transfers to the new test center from Newhall recently.

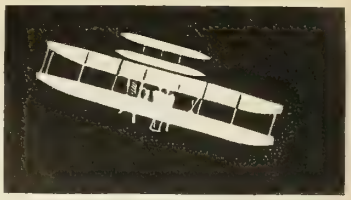
•

Marquardt Aircraft added 300 people to its payroll in one month this summer, highest monthly hiring record since the company's formation. Total is now 3500. Expansion of Marquardt's Van Nuys plant reflects the more realistic view taken by the Air Force toward dispersal. When the late Harold Talbot was secretary and running the show, plans were to move everything to Ogden, including the executive offices. Now research and development stays in Van Nuys with production at Ogden. Marquardt has 450 employes at Ogden where it is now turning out Y ramjet engines for the *Bomarc*.

•

Ryan Aeronautical has completed transfer of all *Firebee* jet drone missile assembly activities to its new Torrance division. Included are final assembly, sub-assembly, electrical shop, painting and engine run-up operations. Fabrication work remains in San Diego. The old *Firebee* final assembly building at the east end of the Ryan Plant at San Diego is now being occupied by Douglas DC-8 pylon main assembly fixtures.

•



Fred H. Rohr, chairman of Rohr Aircraft Corp., says his company expects to participate in missile programs when production manufacturing gets under way. Rohr has been phenomenally successful in the development of aircraft manufacturing techniques, particularly in the field of power packages, and rates very high with old customers like Boeing, Convair and Lockheed. The Chula Vista company undoubtedly will become an important sub-contractor in missile production when the market is ready.

•

Douglas Aircraft's Elizabeth, N. C. division, which started out to be a second source for the *Nike*, is now the sole source, following the Army's transfer of all production on the ground-to-air missile from Santa Monica. But Santa Monica isn't hurt particularly. It can make use of both facilities and manpower on its nuclear tipped air-to-air MB-I *Genie* program. The potential here is very high. This rocket is reported to be so good you might describe it as being "almost as good as they say it is."

•

Air Force cancellation of the *Navajo* was not as abrupt or unexpected as the Los Angeles press made out, but it was a mistake in view of the fact that it came after around $625 million was spent on the program. For that much money the Air Force should have carried it on a little further, or it should have cancelled it before it spent so much. Most people out this way, of course, think the program should not have been cancelled.

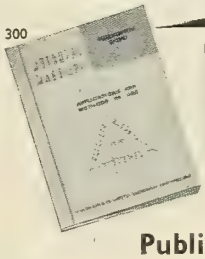
But this is the age of

LIQUID OXYGEN

You can produce your own liquid oxygen with a Supairco plant, available in sizes up to 25 tons per day, with provisions for production of liquid nitrogen and argon as additional products.

Refrigeration is provided by a slow speed, heavy duty, single stage expansion engine.

High efficiency is attained in these plants through the use of a time proved cycle of our own design, the result of a quarter century of experience in the low temperature field.



Catalog on request.

people

Anthony Drabicki has been appointed chief application engineer for fluid systems and components for the Waldorf Instrument Co. The company, a division of F. C. Huyck & Sons, also named **John Borah** as southwestern sales manager.

Dr. Martin J. Gould is now director of research at National Electronics Laboratories, a subsidiary of Thiokol Chemical Corp. Dr. Gould recently served as research specialist at the missile test center, Patrick AFB. He will direct guided missile research at NEL with two assistants, **K. W. Hoover** and **H. R. Corbett, Jr.,** both of whom were also at Patrick's missile test center previously.

Willard D. Walker has been appointed chief electronics engineer at Convair-Astronautics.

William H. Shapiro has been appointed manager of engineering services for the rockets division of Bell Aircraft Corp. Shapiro has been with Bell since 1936 and worked on the first jets produced by the company, as well as the X-1 series of rocket-powered planes.

James B. Kendrick has joined the guided missile research division of Ramo-**Wooldridge** Corp. as chief of preliminary design. Kendrick was formerly instructor of aeronautical engineering at MIT.

Stephen J. Jatras has been appointed to the newly-created post of assistant to the director of Lockheed Missile Systems Division's research and development branch at Palo Alto. Jatras will be succeeded as manager of the R & D coordination division by **Russell L. Reiserer,** formerly assistant chief of the fighter design branch, Navy Bureau of Aeronautics.

Frank S. Wyle has formed a national organization of sales and service engineering specialists in missile testing which will represent independent testing laboratories and test equipment manufacturers.

Dr. Sholom Arzt, research physicist who worked on the *Terrier* and *Talos* missiles, has joined Universal Transistor Products Corp.

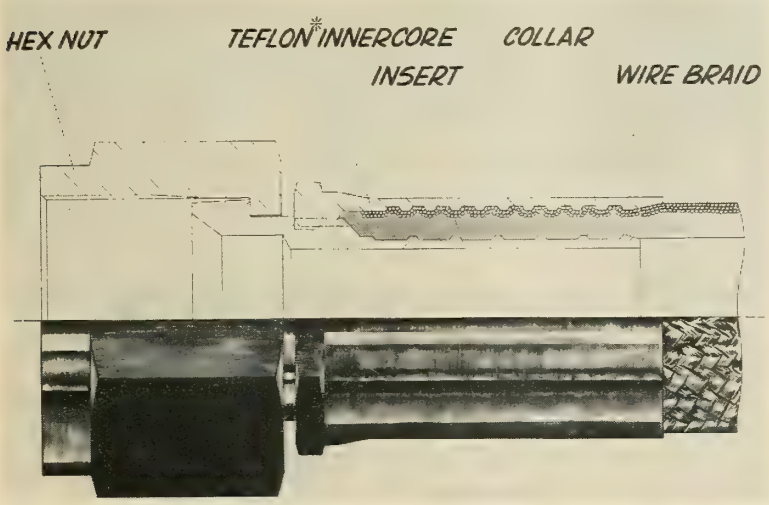
Brig. Gen. Romulus W. Puryear has been named Chief of Staff for Headquarters, Air Defense Command. He assumes his post after having served as Commander, 25th Air Division at McChord AFB, Washington.

Lt. Col. Carlo R. Tosti has been named director of information services for ARDC succeeding Col. **Albert A. Arnhym,** who is being reassigned to SAC.

John B. Pearson (RADM, USN, Ret.) has been named director of development planning for North American Aviation. He will head a new corporate office responsible for analysis and coordination of planning for future product developments.

U. Victor Turner is newly-appointed general manager of Vitramon, Inc., producers of electronic components, and will direct all plant operations of the company.

Edwin R. Gamson has joined Telemeter Magnetics computer memory producer, as director of manufacturing. He was formerly reliability coordinator for Autonetics Division of North American Aviation.



Four appointments to the newly-created Policy Advisory Board of Argonne National Laboratory, the AEC's R & D center, have been made. They are **H. R. Crane,** University of Michigan; **Robert C. Gunness,** vice-president, Standard Oil Company (Indiana); **George A. Hawkins,** Purdue University; and the **Very Rev. Theodore M. Hesburgh,** president of Notre Dame University.

NEW MISSILE PRODUCTS

PERMANENT FITTING FOR FLEXIBLE LINES

A new type of permanent fitting, described as optimum in both design and performance, has been developed by Titeflex, Inc. Flexible lines equipped with the fittings have exceeded MIL-H-25579 (USAF) and are applicable to 1500-psi fluid systems in missiles and rockets.

The amount and direction of flow of both the plastic and wire braid are carefully controlled to obtain the optimum distribution of forces between the hose and the fitting. The seal does not leak

As shown in the figure, the hose is retained between an insert and a collar. Originally a loose fit over the wire braid, the collar diameter is reduced a predetermined amount by radial pressure applied progressively along its length in a rotary hydroforming machine. The plastic innercore and the braid are worked forward toward the hex nut, resulting in a lock between braid and fitting, and between innercore, braid and insert.

in a temperature range from —70°F to 450°F. Titeflex reports that they have never had a fitting blow off a line during their entire test program.

The company has straight fittings, 45° and 90° elbows, and sizes range from 3/16″ nominal hose diameter up to 1¼″ hose diameter.

Circle No. 220 on Subscriber Service Card.

FLIGHT CONTROL ACCELEROMETER

A remote-control electric actuating device has been made an auxiliary feature

in the Genisco model DDL accelerometer now in production. The new configuration is designated the model DDT and embodies a pair of miniaturized solenoids which permit either pre- or in-flight simulation of full-scale operational accelerations by displacement of the sensory mechanisms.

The device is useful when rapid functional tests are required to insure instrument reliability prior to or during flight. Inclusion of the device does not modify the performance of the standard DDL model.

Complete performance and environmental figures are available from the company.

Circle No. 210 on Subscriber Service Card.

ALL-PURPOSE OSCILLOGRAPH

An improved model of the Hathaway S-25 oscillograph has been introduced by

the company, a division of Hamilton Watch Co. The unit, named the S-25C, is a multi-element, all-purpose oscillograph designed for unlimited application, convenience of operation and high-quality recording. The device is cartridge-loaded and uses 12″ wide recording paper capable of recording 18 or 48 channels.

Circle No. 206 on Subscriber Service Card.

ALIGNMENT DEVICE

A device to monitor inertial guidance systems has been developed by Perkins-Elmer Corp. The instrument is designated the Model 169 Auto-Theodolite, and makes it possible to align inertial guidance systems in missiles by detecting angular displacements in the azimuth alignment of the basic monitored equipment.

Functioning of the device is as follows: Two modulated glow lamps in the optical unit of the theodolite direct to the mirror of the monitored system. If the gyro in the guidance system is perfectly squared with the optical axis of the theodolite, the reflected light from the mirror reenters the theodolite objective and is lost back in the light source. If the mirror in the monitored unit is rotated slightly in azimuth, the returning light beams will not be centered on the optical axis and some energy will enter a light-responsive device through a slit. This energy is transduced to an electrical signal which indicates an error in alignment. A corrective signal can then be applied manually or automatically to the drive elements of the monitored system.

The Auto-Theodolite consists of three major components—an optical unit, mount unit and electronic unit. Two distinct and independent systems comprise the optical unit—a supporting base with levelling means and a precision optical limb and reading system for setting off the desired angle between the two optical axes. The theodolite has the electronic control box mounted directly on it to form a compact and readily accessible unit.

Circle No. 228 on Subscriber Service Card.

VARIABLE TIMER

Universal Winding Co. has developed a variable timer for use in missile sys-

tems, programming devices and explosive element initiation. The unit provides for a settable time delay between 0.3 and 10 seconds, with an accuracy of ±5%, and output energy in excess of 35,000 ergs. Temperature ambients from —70°F to 165°F and accelerations up to 100 g's have no effect on the device, which is termed the PM-47.

Transient circuits are used to achieve the delay, which is furnished by components of the weapon approved non-

power-consuming type, i.e., no tube filament power, etc., is required. The selected time delay is obtained by applying between 100 and 400 volts to the device, depending on the delay desired. The delay is initiated by release of a pull wire which allows a spring driven plunger to complete the necessary switching action. At the close of the delay period a pulse of electrical energy is applied to the load.

Circle No. 201 on Subscriber Service Card.

PRECISION STEEL TUBING

Recent order of stainless steel tubing by Carpenter Steel Co. for AEC met tolerances of +.000" —.025" and similar tolerances are available from the company. The tubing is available for missile & rocket applications. It may be covered with insulating material if necessary. Operating temperature on AEC order is said to be 2000°F.

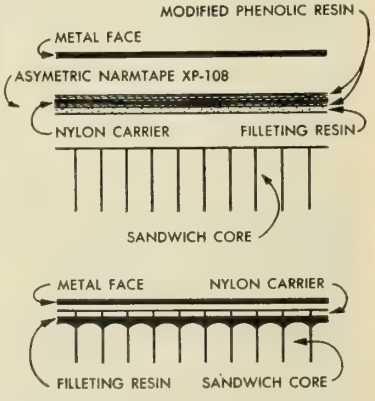
SECONDARY PRESSURE STANDARD

A pressure standard for calibration of pressure instruments and for making



direct pressure measurements is being introduced by Wianco Engineering Co. The portable, compact unit has an overall accuracy of ±0.05% of full-scale ranges of 5 psi to 2500 psi, and ±0.1% for ranges of 3000 psi to 10,000 psi.

The unit weighs 25 lbs., has interchangable pressure heads, and only one secondary standard is necessary for any number of pressure heads. The unit's output may be displayed on a frequency counter or recorded in digital form on standard digital printers. The device is adaptable to measure other parameters, such as force, acceleration and displacement.

Circle No. 204 on Subscriber Service Card.

STRUCTURAL ADHESIVE

An adhesive designed to eliminate the need for core priming in missile sand-

wich component fabrication and also to provide materially improved peel strength, has been developed by Narmco Resins and Coatings Co. Tradenamed "Narmtape XP-108," the new adhesive is said to be the first asymmetric structural adhesive available to the missile industry, and consists of a nylon carrier impregnated with a modified phenolic resin. It is overcoated on one surface with a highly mobile filleting resin.

The addition of this filleting resin, according to Narmco, will eliminate the priming step of bonded sandwich construction operations. The new adhesive is resistent to fuels, salt spray, solvents and corrosive materials.

Circle No. 202 on Subscriber Service Card.

CIRCUIT TESTER

A device capable of testing 1200 electrical circuits in a minute has been introduced by Republic Aviation Corp. The automatic circuit analyzer is simple to operate and can be used on any multiple-circuit assembly. Removable program boards that mate with a receiver mechanism can be employed to reduce costs. The analyzer not only detects reversed, shorted or open circuits, but also determines immediately all those circuits involved.

Five models of the checker have been designed with capacities of 200, 400, 800, and 1200 circuits, in addition to a 100 circuit light-weight portable model for field use. The units can be built to operate from any power source and no modification is necessary to test different types of circuit harnesses, the changeover between types achieved with plug-in, pre-assembled adapters. An automatic megger to detect current leakage through wiring insulation is optional. Other special requirements can be built to customer specifications.

Circle No. 229 on Subscriber Service Card.

AUTOMATIC MOTOR TESTER

Servo-motors of 1/50 to 1 hp capacity, as well as other motor types, may be

tested in a new test stand developed by Magtrol, Inc. The test stands are designed to completely test a motor in three or more dynamic phases of torque, speed and current characteristics and feature four-digit electronic tachometers to indicate motor speed.

Seven basic dynamometer heads are available, covering the range from 1 oz. in. to 750 oz. in. torque capacity, and capable of checking motors in three phases: no-load check of speed and current; dynamic check of speed, torque and current; second dynamic check of speed, load and current at any point on the curve, of stall current and stall torque check.

The control sequence may be initiated manually by a single start button for each phase, or it may be sequenced automatically.

Circle No. 200 on Subscriber Service Card.

NEW LOW-NOISE CHOPPER

Bristol's Syncroverter† chopper is now available in a low-noise, external-coil model for critical dry circuit applications.

This new external-coil chopper virtually eliminates capacitive coupling between signal-circuit contacts and driving coil leads. Peak-to-peak noise levels are usually *less than 100 microvolts* across a 1 megohm impedance (rms noise, in the order of 10 microvolts).

LONG LIFE and immunity to severe shock and vibration are outstanding characteristics of the new Syncroverter chopper. Withstands vibration, 5 to 2000 cps, up to 30G, and up to five 30G impacts on any major axis. SPDT switch action. Nominal contact ratings: up to 10 V, 1 ma.

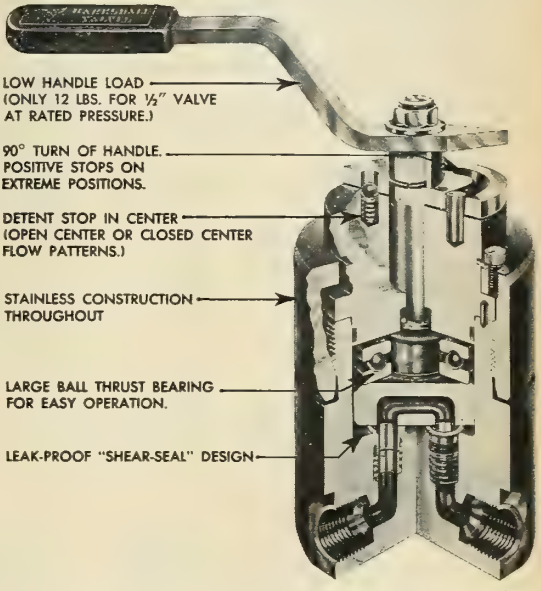
Write for complete data on this latest addition to the Bristol Syncroverter line. The Bristol Company, 173 Bristol Road, Waterbury 20, Conn. 7.31

†T. M. Reg. U. S. Pat. Off.

TYPICAL CHARACTERISTICS

Driving Frequency Range:	0—1800 cps
Coil Voltage:	6.3 V sine, square, pulse wave
***Coil Current:**	70 milliamperes
Coil Resistance:	52 ohms
***Phase Lag:**	60° ± 10°
***Dissymmetry:**	15° max.
***Switching Time:**	15° ± 5°
Temperature Ranges:	—55°C to 100°C or —65°C to 125°C
Operating Position:	Any
Mounting:	Flange; 2-hole or 4-hole Plug-in; fits 7-pin miniature socket

*These characteristics based on sine-wave excitation, 400 cps.



BRISTOL FINE PRECISION INSTRUMENTS FOR OVER 68 YEARS

Circle No. 104 on Subscriber Service Card.

10,000 P.S.I.

4 WAY VALVE

FOR LIQUIDS OR GASES

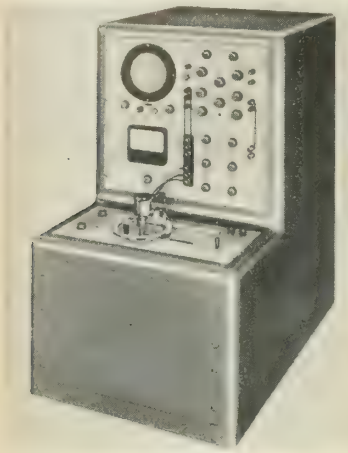
This new four-way valve series comes in pipe sizes from ¼ to 1 inch, but may be obtained with tube, AND 10050, or any preferred special high pressure connection. It will withstand surges of up to 15,000 P.S.I. without damage to the valve's sealing qualities. It is designed for a burst pressure of 30,000 P.S.I.

No port to port leakage occurs in the detented positions because of the exclusive "Shear-Seal" design.

Long, maintenance-free service is assured because the optically flat metal to metal sealing surfaces of the sealing rings and mating rotor faces are protected by staying in constant intimate contact; flow is always through the center of the "Shear-Seal", never across sealing surfaces (as in conventional valve design). Sealing qualities actually improve as the self aligning "Shear-Seals" lap themselves to a more perfect fit with each valve operation.

Of course, there is no external shaft leakage, because the pressure is confined to the flow passages.

This highly successful principle of extreme pressure control is fully described in "Shear-Seal" bulletin BVM-2.



BARKSDALE VALVES

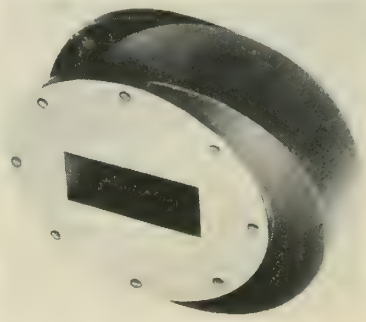
5125 Alcoa Avenue, Los Angeles 58, California

Circle No. 105 on Subscriber Service Card.

LINEARITY TESTER

Linear accuracy in precision potentiometers may be tested with the model TP-800 tester of Technical Products Co.

Use of a long persistent oscilloscope provides display of error signal, and noise due to contact resistance over frequency range of 0 to 100,000 cycles. Individual wire commutation may be shown. Magnetic clamping allows rapid set-up and alignment of test potentiometers.

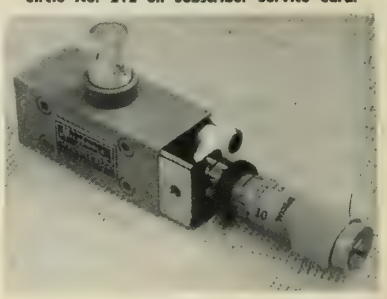


The unit's oscilloscope reads linearity error directly in per cent, in five ranges from .05 to 1.0 per cent of full scale, with accuracies of 0.01%. Terminals provided for recorder operation. A motor-driven precision gear box couples a 40-turn master helipot of .007% linearity to the test potentiometer.

Units of 1, 3, 10, 15, 25, and 40 turns can be accommodated. Test voltages may be selected between 22.5 and 135 volts to give maximum sensitivity for each unit being tested.

Circle No. 222 on Subscriber Service Card.

FERRITE MINIATURE ISOLATOR



Airtron, Inc. is offering a "C" band 150 kw ferrite miniature isolator designed to operate in the 5000 mc frequency range.

The resonant absorption isolators furnish constant uni-directional magnetron to load isolation and feature a waveguide size of 2.00 x 1.00 O.D. with a weight of less than 3.5 lbs. Electrical characteristics guarantee an isolation of 10 db minimum, insertion loss of 0.5 db maximum, input VSWR 1.10 maximum with matched load and power handling capabilities of 150 kw peak power with 100 watts average into a 2 to 1 mismatch.

Ferrite material is mounted directly on the waveguide wall and full waveguide opening has been used. Heat conduction away from the waveguide is said to be rapid enough to allow operation without forced air cooling. Five units are available to collectively cover the frequency range 5250 to 5750 mc/s.

Circle No. 212 on Subscriber Service Card.

TUNABLE THERMISTOR MOUNT

A Ka-band tunable thermistor mount, with thermistor, designed for sensitive measurement of RF power in RG-96/U waveguide transmission systems is available from Microwave Associates, Inc. Frequency coverage of the unit is 34.0—36.0 kmc/s with maximum VSWR of 1.5.

The unit may be used over the complete waveguide range if higher input VSWR's are not a consideration. Nominal operating resistance is 200 ohms and power handling capacity is 10 milliwatts maximum. Insertion loss is determined at 34.86 kmc/s and the value marked permanently on each unit and the accuracy of the measurement is ± ¼ db.

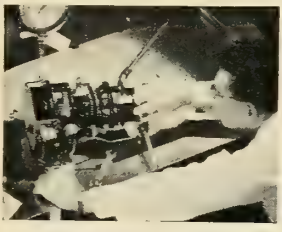
THERMAL SWITCH

A hermetically-sealed two-wire thermal switch designed for use in bearings, pipes, etc., and using a bimetal element

n a stainless steel body has been introduced by Control Products, Inc. The switch operates in ambient temperatures from —65°F to 700°F, has an electric rating of 2 amps and is resistive at either 28V dc or 115V ac. Length over AN connector is 5/16" and it is designed to meet environmental, shock and vibration requirements of MIL-E-5272A.

Circle No. 215 on Subscriber Service Card.

THREE-WAY VALVE



Designed for highly corrosive materials, this valve features flow through any two selected ports, while automatically shutting off the third port. Valve operation employs a self-wiping and self-lapping action which is free of wear-producing shocks and needs no lubricants

TEST EQUIPMENT

The Test Equipment Engineer is engaged primarily in the design of specialized missile check-out equipment. As missiles push the state of the art, test equipment must exceed the missiles in precision and reliability. Automatic programing, go-no-go evaluation, and automatic data processing add up to automation in missile testing.

This engineer is evaluating his design of a precision power supply—one of the building blocks that will be system engineered into a family of versatile matched missile and sub-system test equipment. Engineers work as individuals.

HYDRAULIC DESIGN

Excellent opportunities are available for the engineer to observe the performance of his design. Here, under the watchful eyes of its designer, a hydraulic power unit is undergoing adjustment and setting prior to severe testing at simulated high altitude conditions.

Many components, which a few months ago seemed almost impossible to design, are now being tested under the severe conditions required to qualify them for flight operation—and passing with flying colors.

STEERING INTELLIGENCE

Two Steering Intelligence Engineers discuss space allotment in a new guidance component. This close association of engineers with the "flying" equipment is typical of the Steering Intelligence Section. Engineers in this section are primarily *and directly* concerned with refining the guidance equipment to steer the missile with greater accuracy, at greater ranges and with simpler and more reliable electronic equipment and, consistently, with minimizing the cost. Work is actively in progress in every principal field from microwave equipment to inertial end instruments.

Bendix

PRIME CONTRACTOR FOR TALOS MISSILE

Offers more interesting and challenging job opportunities!

If you are interested in guided missiles, you will be especially interested in Bendix. As prime contractor for the important and successful Talos Missile, the job opportunities here cover the widest possible scope, and the opportunities for advancement are practically unlimited.

Here is a compact, hard-hitting organization backed by all the resources of the nation-wide Bendix Aviation Corporation—an organization dedicated to the design and production of the finest in guided missiles.

If you can accept a challenge, want an opportunity to grow with a leader in its field, and can accept the responsibility that goes with opportunity, send for the thirty-six-page book "Your Future in Guided Missiles". It gives the complete, detailed story of the function of the various engineering groups and the many job opportunities available for you.

Just fill out the coupon. It may help you plan a successful future in the guided missile field.

Bendix Products Division—Missiles
412 L. Bendix Drive, South Bend, Indiana

Gentlemen: I would like more information concerning opportunities in guided missiles. Please send me the booklet "Your Future In Guided Missiles".

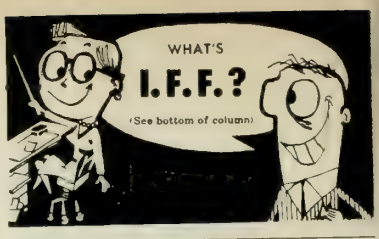
Missile Development Engineers

Electrical • Electronic Engineers with 2-6 years experience in

Magnetic and Transistor Amplifiers
Electrical Circuitry
Network Design
Inverters
Electro-Mechanical Analog Computers
AC and DC Servo Motors
Electronic Research
Missile Control Systems

Mechanical Engineers with 2-6 years experience in

Inertial Guidance Systems
Gyro Development
Product Design and Packaging
Servomechanisms



Ford Instrument Company's new Missile Development Division is expanding because of increased activity on guidance and control work for major ballistic missiles such as the Redstone and Jupiter.

Are you interested in the opportunities this could bring you — and the increased responsibilities? To those engineers who feel they can measure up to the high standards of our engineering staff and who wish to do research, development and design work in the expanding new field of missile engineering, write or phone Allen Schwab for an appointment or further information.

that might contaminate fluids.

Also available from the company, Progressive Research and Development Co., are 2- or 4-way valves from ½" to 1½" and operating pressures up to 3500 psi, as well as LOX shut-off valves for line sizes up to 3".

Circle No. 223 on Subscriber Service Card.

DIGITAL FLOW INDICATOR

A digital flow indicator and totalizer, which gives a direct reading in gallons per minute or per hour, can be adjusted to specific gravity changes to give readings in pounds per minute or hour, and will give direct readings of speed in revolutions per unit time has been announced by Potter Aeronautical Corp.

When used with two Pottermeters, the instrument, designated Model 43, will indicate the ratio between two flows. It samples desired information for a controlled sample period, and is adjustable from 1/10 millisecond to 10 seconds in increments of 1/10 millisecond.

The unit is suitable for all types of flow rate measurement and may be used as a short-time totalizer with a four digit readout in ¾" high figures on Burroughs Nixie Tubes.

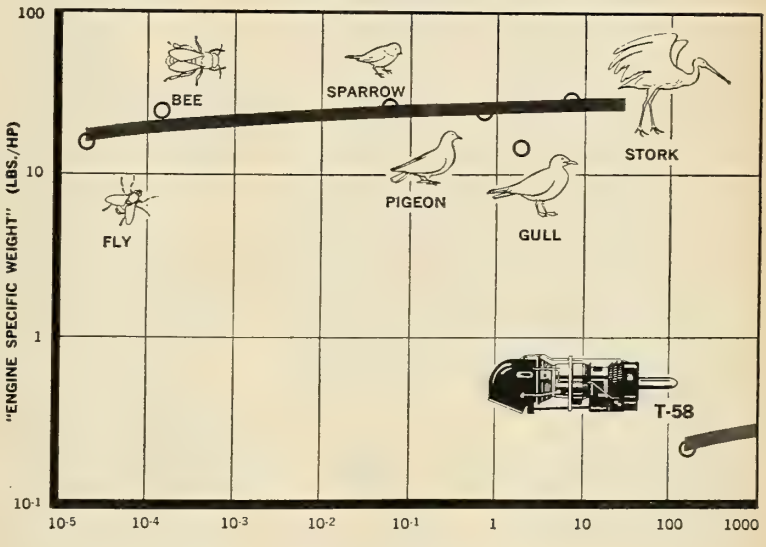
Flight Propulsion–

Some Aspects Pointing Up Engineering Opportunities in Small Aircraft Gas Turbine Engineering



FROM STOKE'S LAW for the very small to Hoyle's work with the very large, the "3/2 power" principle maintains its validity. For an example in the middle range of our immediate experience, note the curves on the chart (1).

The variation of propulsive thrust with the square, and of "engine" weight with the cube of linear dimensions results in the well-known fact that propulsive efficiency increases with decreasing power plant size...whether one studies insects, birds, or aircraft gas turbines.

For the engineer who is curious about the application of engineering principles in nature, we recommend D'Arcy Thompson's "Growth and Form".

For the engineer who is specially curious about the small curve on the plot, we can recommend no better course for *him* than to contact Roger Hawk of General Electric's Small Aircraft Engine Department.

Engineers at SAED are busy extending the 3/2 principle to AGT applications. The success with which they have met in developing *small* highly efficient power plants (2) has created many new openings for engineers with strong backgrounds in AGT work.

"ENGINE SPECIFIC WEIGHT" VS. WEIGHT

Some of the particular components demanding the attention of capable engineers are: combustors, controls, exhaust nozzles, frames, reduction gears, rotors and blading.

If you feel that you would like to put your degree and AGT experience (3) to work in the exacting region of that small lower curve, you can get additional details on these positions from Mr. Hawk.

NOTES AND REFERENCES

1. Values for the "engine specific weight" of the insects and birds were derived from Thompson . . . cf. "Growth and Form," 2nd Ed., 1942, Cambridge University Press; Chapter II on magnitude, especially pp. 45, 47. Birds were assumed to fly at 30 mph, insects at 5 mph.

2. The T58 Turboshaft — 250 lbs. without reduction gear, 1050 HP — now in production. The T64 Convertible — for turboprop or turboshaft use, depending upon gearing — now in development; the J85 Turbojet — details still classified.

3. A degree in engineering or science, plus AGT experience qualifying you for combustor, compressor, turbine and other mechanical design, field and flight test, aerothermodynamics, fluid mechanics, accessories and systems, engineering liaison.

SUBSCRIBER SERVICE

For additional information about any product or service advertised or mentioned in the editorial pages of this issue of Missiles and Rockets:

Use the attached prepaid reply cards. Circle numbers shown on the reply card that correspond with numbers appearing beneath items described. If no circle number accompanies the article or advertisement, give page number (and advertiser's name) on line provided at bottom of the card.

Your requests for information will be forwarded promptly to the companies concerned.

NEW PRODUCT BRIEFS

QUID PROPELLANT HOSE. A new ose capable of handling concentrated ydrogen peroxide without causing de-omposition of the liquid, or being ffected by it, is available in sizes up 6" ID and in lengths up to 50 feet. ewitt-Robins, Inc.
rcle No. 240 on Subscriber Service Card.

F COAXIAL CONNECTOR. Feather-eight type N and HN hermetically aled RF coaxial connectors meet spec-cation MIL-E-5272A. The unit weighs 45 oz. and has a constant impedance 50 ohms. Don-Lan Electronics Co.
rcle No. 241 on Subscriber Service Card.

RING ASSORTMENT. Assorted rings for experimental purposes in-ude a variety of sizes and types. rings made of beryllium copper, rome-silicone, high-nickel alloys, steel usic wire, corrosion-resistant wire and her materials are included. California ring Co.
rcle No. 242 on Subscriber Service Card.

JLCANIZED FIBRE weighing half as uch as aluminum but .9 times as ong is available as protective packag-g material for missile components. eets specifications MIL-F-1148 and IL-I-695A. National Vulcanized Fibre
rcle No. 243 on Subscriber Service Card.

RRITE ISOLATORS. Series of test uipment isolators covering broad fre-ency ranges. Waveguide sizes ob-nable in variety of flange combina-ns. Airtron, Inc.
cle No. 251 on Subscriber Service Card.

RIABLE INDUCTORS & COILS. mponents designed for printed cir-it use, covering 2 to 2000 microhenry ge and the 1.5 millihenry to 1.0 ry range. Complete information and talog available. North Hills Electric.
cle No. 252 on Subscriber Service Card.

INTED CIRCUIT MATERIAL. Copper d Teflon sheet and tape for printed cuit and cable strip applications. s a uniform low dielectric constant l no delamination of insulation ma-ial. Fluorocarbon Products, Inc.
cle No. 253 on Subscriber Service Card.

TARY SELECTOR SWITCH. Nine-ition, one-pole switch operates con-ously at 250°F, or intermittently at °F, is electrically rated at 6 amps istive load at 115V ac and 28V ac 3 amps inductive load at 28 dc. ico Corp.
cle No. 254 on Subscriber Service Card.

TRANSFER FUNCTION ANALYZER. Potential users invited to make own one-week test and evaluation of servo test equipment. Unit is designed to test servo-mechanisms under conditions where servo output may be non-linear. Solartron.
Circle No. 244 on Subscriber Service Card.

UNIVERSAL STABILIZED AMPLIFIER. Compact, chopper-stabilized unit has open-loop dc gain of 10 million, output range of ±115 V, and accuracy maintained beyond 1 kilocycle when used at 100 gain. Philbrick Researches, Inc.
Circle No. 245 on Subscriber Service Card.

ANEMOMETER. Constant-temperature hot wire anemometer has frequency response of dc to 1000 cps and noise level is less than 1% of mean flow level. Three of the units fit into a 19" rack. Other systems available. Aero Research Instrument Co.
Circle No. 246 on Subscriber Service Card.

ELECTRONIC BATTERY. Model 170 battery input is 105-125/210-250 volts, 50/60 cps. Output is 6 volts adjustable ±5%, 0-5 amps; 2 volts adjustable ±5%, 0-100 amps. Has high stability and low noise. American Electronics Laboratories, Inc.
Circle No. 247 on Subscriber Service Card.

RADIATION MONITORING SYSTEM. Self-contained battery-operated unit measures, displays, records and controls alarms for gamma radiation from background .025 mr/hr to 100 kr/hr or higher in the energy range from 80 kv to 1.5 mev. Riggs Nucleonics Co.
Circle No. 248 on Subscriber Service Card.

CERAMIC MISSILE RADOME. High-temperature radar-transparent ceramic radomes with the hardness of diamonds have been developed by Gladding McBean & Co.
Circle No. 249 on Subscriber Service Card.

SYNCHRO INDEX STAND. Mechanical device for holding and accurately locating rotor shaft of synchros to desired angular position. Determines various parameters such as electrical error, etc. Kearfott Co., Inc.
Circle No. 250 on Subscriber Service Card.

ROCKET BLAST FENCE. A blast deflection and noise reduction fence for use in missile and rocket launching operations. Utilizes a 2" perforated water line at its leading edge to allow water, controlled by a thermostatically operated valve, to flow over the surface of the fence. Lynn Engineering Co.
Circle No. 255 on Subscriber Service Card.

When it has to be heated

rely on Safeway Woven Heat Elements

. . . and the "it" can be just about anything from a simple tray to the curing blankets for honeycomb structures.

Safeway Woven Heat Elements are custom tailored to fit specialized requirements of many applications. A single aircraft, for example, may need upwards of 80 different heating and de-icing elements, all of which are made by Safeway. Other applications are on helicopter rotors, rocket tubes, missile launchers, and on a wide variety of molds, dies, tanks, ovens and dryers in industry.

If you have a problem that requires heat, let Safeway engineers study your requirements and—without obligation to you—submit an appropriate recommendation.

For your copy of a fact-filled folder, write to:

FROM BLANKS TO BULKHEADS!

The Diversey craftsmen above is machining the inner diameter of a Forward Bulkhead of the Hawk missile to a fine 63 microinch finish. Notice the precision curved template in the center of the picture with the follower at the right end transferring the contour to the interior of the bulkhead. Another good example of the famous air gage tracer lathe technique that has brought the missile hardware field to such an advanced state.

Diversey starts with blank forgings. Using their remarkable ability to integrate hydrospinning and contour turning techniques Diversey craftsmen are able to produce the finest and most precise missile and rocket hardware components.

At Diversey you have the LARGEST FACILITIES exclusively devoted to your missile hardware production. Your work is handled by precise, fast, and progressive technical people. Contact Diversey on your tough jobs.

HYDROSPINNING NOW AVAILABLE

Diversey announces the formation of a new Hydrospinning Division with the acquisition of new Hydrospin equipment up to 42" capacity.

From Air Force to Space Force

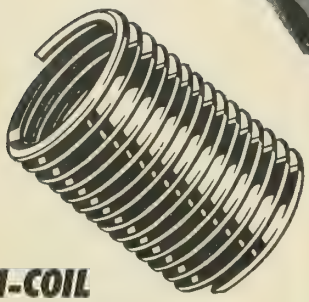
Washington defense planners and Air Force officials were jolted recently by a brilliantly written article in LOOK magazine. With the cover headline "The Coming Death of the Flying Air Force," LOOK introduced to the man in the street one of today's most thought-provoking topics. This inevitable article expressed the views that Air Force people themselves have been too frightened to mention in the open. This is in spite of the fact that AF experts such as General Nathan Twining have warned that the AF must encounter considerable cuts in terms of manned planes and that missiles are on the way in.

The LOOK article meticulously detailed the increased use of missiles in place of aircraft—a view that we have shared and expressed in our columns since our very first issue. Nevertheless, the LOOK article built chronologically to the "coming death of the flying Air Force," implying that with the ascendancy of the missile in current military concept there would be no need for a separate air force.

We disagree with this view. You don't need to be an expert to foresee that the Air Force will continue to be our most important arm of retaliation for immediate action against any Russian blow against the Free World. But the Air Force gradually will become a Space Force—with clipped wings, with rocket ships instead of airplanes. By-and-by our Air Force will have to build up a space force system. Today's fighter squadrons will become space reconnaissance squadrons tomorrow. Goodbye to the pilot? No, tomorrow's rocketcraft will be manned. They will be manned by a new breed of pilot. Col. John P. Stapp, Maj. David Simons and a few others are paving the way for these pilots of tomorrow. And our space force will pave the way for the new defense system in general.

The question remains, however, whether our Air Force planners fully comprehend all this. Do they have the vision to understand that now is the time for transition from planes to missiles and spacecraft?

The Air Force will never become a Space Force by capriciously cutting Air Force Office of Scientific Research's expenditure rate. It will never become a Space Force if it continues to allow routine personnel action to put out to pasture such pioneering scientific genius as that of Col. William O. Davis, Deputy Commander, Operations, AFOSR.

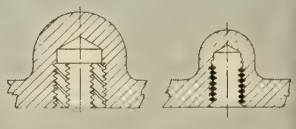


AFOSR has one of the smallest budgets in the country. Yet, for the future of America's military security, for man's advance into space, there is no office or agency that is more important. Nor in the experience of this country's rocket men is any one more capable of aiding and abetting this advance than Col. Davis. The murmur of protest at the AFOSR budget cut has swelled into a rumble, and top Pentagon planners had second thoughts. The money has been reinstated. There are no such reports however that minds will also be changed about Bill Davis' impending transfer to conventional duties in Dayton.

The fact that AF would cut its exploratory research budget and shuffle off one of its most practical and imaginative researchers is bad enough in itself. What is more fundamental, however, is the existence of thinking in high places that would permit such actions to occur. It is the thinking of men chained by links with the past and blinded by the brilliance of the future, of men who think tomorrow will be just like today. It is the kind of thinking that will, in fact, make the LOOK article a forecast of things to come; that will in fact assure the "Coming Death of the Flying Air Force."

ERIK BERGAUST

Here's Use



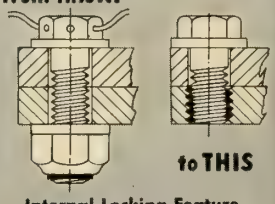
HELI-COIL Stainless Steel Screw-THREAD Insert

This is the insert that permanently protects threads against wear, stripping, corrosion, galling, seizing, vibration and shock. Made of (18-8) stainless steel wire, cold-rolled into a diamond shaped cross-section, this ***Heli-Coil*** Insert is work hardened to a tensile strength of approximately 200,000 psi . . . conforms to military standards MS 122076 through 122275 (ASG) and MS 124651 through 124850 (ASG) . . . conforms to standard commercial and industrial thread forms, including coarse, fine, pipe-thread and MM sizes . . . permits use of standard boss configurations.

Here Are

Save Space, Weight and Costs

Substantial savings in materials, weight, space and costs are possible, as against solid bushings, because smaller (or standard) bosses, flanges and threaded fasteners can be used.



New HELI-COIL Stainless Steel Screw-LOCK Insert

Pat. Pending.

Conforming to military specifications for locking torque and vibration, this notable new ***Heli-Coil*** Screw-LOCK *one-piece* insert provides all the thread protection of the Screw-THREAD Insert, **PLUS** an exclusive internal locking feature that eliminates the need for clumsy protruding lock nuts, lock wiring and other supplementary locking devices . . . saves cost, space and weight . . . permits simplified streamlined design. The Insert is a permanently integrated part of the component—permits repeated service repair disassembly and reassembly, *with locking action remaining unimpaired.* Available in sizes from 4-40 up.

Here Are

from this...

to THIS

Internal Locking Feature

Insures positive internal locking action—eliminates lock nuts, lock wiring and other protruding locking devices—saves space, weight, cost. Yet screw may be easily disassembled with no loss of locking torque.

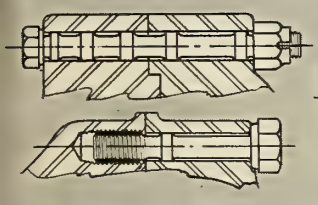
➡ ***Heli-Coil*** **Field Engineers are at your service for**

CUSTOM LOCK NUTS

The ***Heli-Coil*** Screw-LOCK Insert is adaptable to special-shaped lock nuts, shells, spacers and fasteners and can be engineered to meet your torque or performance requirements. ***Heli-Coil Corporation*** is fully equipped to manufacture these special lock nuts to your specifications.

Note: Custom nuts, with Screw-LOCK Inserts, meet military specifications for lock nuts.

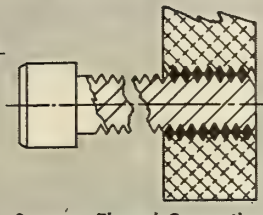
How Design Engineers HELI-COIL* INSERTS to



SAVE: SPACE—WEIGHT—COSTS

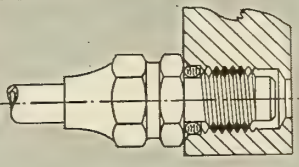
PERMANENTLY PROTECT THREADS AGAINST

ABUSE • WEAR • CORROSION • STRIPPING • GALLING • SEIZING • VIBRATION



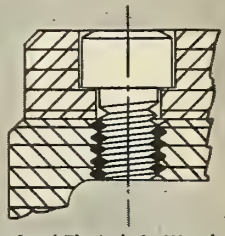
Eliminate Lock Nuts — Lock Wiring — Lock Washers

Some Typical *Heli-Coil* Screw-THREAD Applications



Compact Design

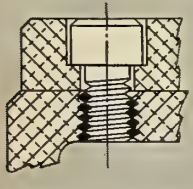
Improves design features by elimination of nuts, washers and extra-length bolts.



Stronger Thread Connections

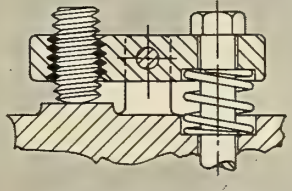
Under excessive tension, torsion and impact loads in standard proportion bosses, the screw will break but the *Heli-Coil* Screw-THREAD Insert will remain undamaged . . . even in light alloy metal.

Leak-Proof Connections



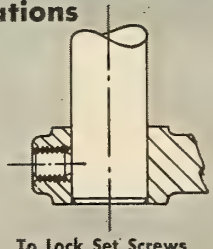
In lightweight, high pressure hydraulic equipment, stainless steel inserts, regular and pipe thread, protect threaded pump and valve ports sealed with "O" rings.

Steel Threads in Wood, Plastics and Fiberglas



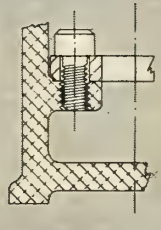
Provides permanent, strong, corrosion-resistant and wearproof threads in soft materials. Especially valuable where frequent assembly and disassembly is necessary.

Some Typical *Heli-Coil* Screw-LOCK Applications



Flush Nut Assemblies

Permits a securely locked, flush assembly, because its internal locking feature eliminates need for drilled head bolts and other protruding locking devices.



Lock Adjustment Screws

This simple design allows permanent, positive adjustment of screws in any position, secure against vibration or impact.

To Lock Set Screws

Positively locks assembly against loosening at desired adjustment — protects threads against stripping under high torque—permits use of light housing materials.

Inaccessible or Miniaturized Assemblies

Heli-Coil Screw-LOCK Insert permits installation of the locking feature from front or top. No blind fumbling for assembly of locking devices inside or behind.

BELL AIRCRAFT'S ACOUSTIC TEST FACILITIES

for Airborne Components and Structural Parts

L to R: Dr. Fricke, Engineer-in-charge Acoustics Laboratory, and Mr. Kuzara Acoustics Engineer, evaluating a component in a high intensity acoustic environment. RIGHT: Malfunction of a relay at high-intensity sound as disclosed in a sound chamber.

Contact resistance at 140 d b sound-pressure level.

Contact chatter of same relay at 150 d b sound-pressure level.

UPPER TRACES SHOW CONTACT BEHAVIOR; LOWER, ACOUSTIC INPUT

The ever increasing speed and power of today's aircraft and missiles produce sound-pressure levels which can adversely affect the reliability of both mechanical and electronic components. The Acoustical Laboratory of Bell's *Research Division* has developed high-intensity sound chambers for analyzing sound effects on airborne components and conducting functional sound tests.

The Laboratory can also provide highly accurate calibration for sound measuring and recording equipment.

The wide experience which has made Bell Aircraft a leader in high-intensity acoustical testing, sound surveys and analyses, and the evaluation of sound-sensitive components is now available to you. To determine how this unique service can supplement your own test facilities, send for bulletin "Acoustic Test Facilities".

SOLID POWER FROM PETROLEUM

The "PRODUCER"—a new Phillips-designed rocket—develops higher thrust than any other known single solid propellant motor available today. Creative engineering which made this rocket a reality has also made possible other advances in design including the longest duration large solid propellant motor ever fired.

The "PRODUCER" uses composite solid propellant made of low-cost ammonium nitrate oxidizer, synthetic rubber fuel binder and additives. Low-cost components, reliable ignition and stable combustion make this motor attractive for a variety of applications.

In addition to the "PRODUCER" Phillips offers a wide range of off-the-shelf solid propellant motors for military use such as the M15 JATO, the "PUSHER" and sled booster motors and very long duration types. These versatile, economical propulsion units can be engineered to meet a variety of thrust, duration and total impulse requirements. The superior reliability, stability and shelf life of Phillips propellants are a "solid" argument for solid propulsion!

We invite you to write and discuss your technical and production problems with us. Or call one of our regional representatives: Washington, D. C.—E. L. Klein, EXecutive 3-3050; Los Angeles—R. O. Gose, GRanite 2-0218; Dayton, Ohio—C. W. Strayer, YOrktown 3263.

SPEED YOUR MISSILE

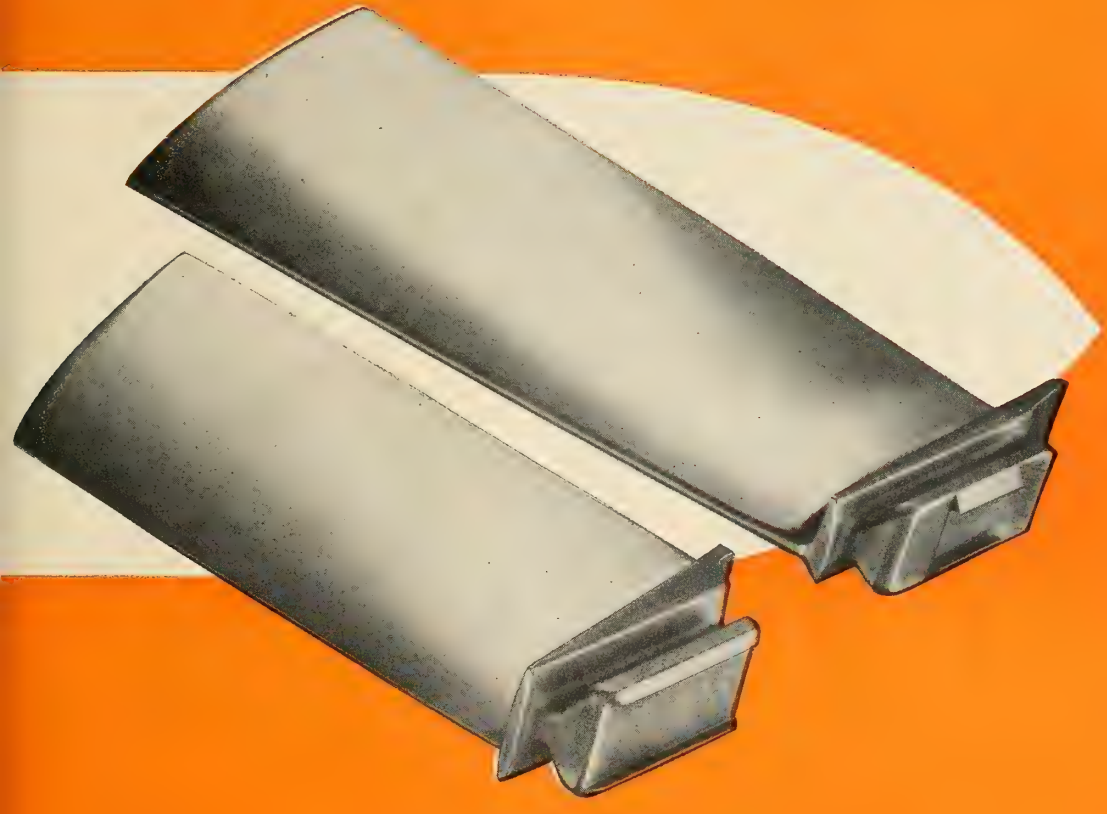
Titanium, Stainless Steel,

FROM THE LEADING PRODUCER

Tolerances as close as ± 0.003″ can be achieved in the high-precision forgings produced at the Jet Division. These precise forgings can be made from titanium, stainless steel or high-strength alloys. For many applications, finish machining is eliminated, saving high labor costs and expensive scrap.

Make the Jet Division a part of your missile production program. By letting us produce forged and machined parts and weldments, you avoid the capital expense of your own facilities, eliminate the headaches of recruiting trained personnel, get your missile program under way faster.

Our engineering and test facilities are also available to augment your missile plant. We can handle the complete job of producing missile air-frames, internal structures, and operating components.



WRITE TODAY FOR BOOKLET MR-457
which describes the engineering and production facilities of the Jet Division. A sales engineer will call at your convenience to discuss our abilities.

PROGRAM WITH

DOUBLE DIAGNOSIS TO PREVENT "HEART DISEASE"

...BY THE B&H JETCAL® ANALYZER

Two of the most important factors that affect jet engine life, efficiency, and safe operation are *Exhaust Gas Temperature (EGT)* and *Engine Speed (RPM)*. Excess heat will reduce "bucket" life as much as 50%, and low EGT materially reduces efficiency and thrust. Any of such conditions will make operation of the aircraft both costly and dangerous. The *JETCAL Analyzer* predetermines accuracy of the EGT and (interrelatedly) Tachometer systems and isolates errors if they exist.

The JETCAL ANALYZES JET ENGINES 10 WAYS:

1) The JETCAL Analyzer *functionally* tests EGT thermocouple circuit of a jet aircraft or pilotless aircraft missile for error *without running the engine or disconnecting any wiring*. GUARANTEED ACCURACY is ±4°C. at engine test temperature.

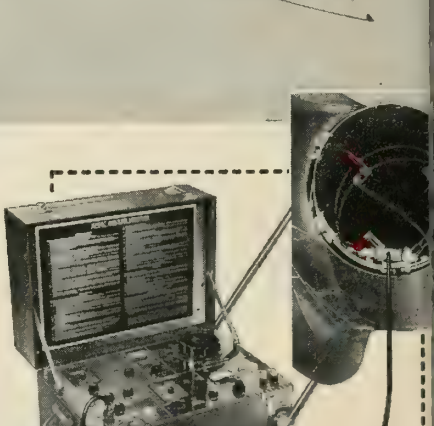
2) Checks individual thermocouples "on the bench" before placement in parallel harness.

3) Checks thermocouples within the harness for continuity.

4) Checks thermocouples *and* paralleling harness for accuracy.

5) Checks resistance of the Exhaust Gas Temperature system.

6) Checks insulation of the EGT circuit for shorts to ground and for shorts between leads.



7) Checks EGT Indicators (in or out of the aircraft).

8) Checks EGT system with engine removed from aircraft (in production line or overhaul shop).

9) Reads jet engine speed while the engine is running with a guaranteed accuracy of ±0.1% in the range of 0-110% RPM. Additionally, the TAKCAL circuit can be used to trouble shoot and isolate errors in the aircraft tachometer system.

10) JETCAL Analyzer enables engine adjustment to proper relationship between engine temperature and engine RPM for maximum thrust and efficiency during engine run (Tabbing or Micing).

ALSO *functionally* checks aircraft Over-Heat Detectors and Wing Anti-Ice Systems (thermal switch and continuous wire) by using TEMPCAL Probes.. Rapid heat rise . . . 3 minutes to 800°F! Fast cycling time of thermal switches . . . 4 to 5 complete cycles per minute for bench checking in production.

Tests EGT System Accuracy to ±4°C at Test Temperature

(functionally, without running the engine)

Tests RPM Accuracy to 10 RPM in 10,000 RPM (±0.1%)

The JETCAL is in worldwide use . . . by the U. S. Navy and Air Force as well as by major aircraft and engine manufacturers. Write, wire or phone for complete information.

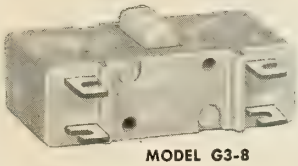
FOUR PROVEN ANSWERS TO SWITCHING PROBLEMS

Subminiature sealed switch is environment-free; mounts interchangeably with MS25085



MODEL EF-3

gle Pole, Double Throw
re. Differential, .004 Max.
rtravel, .003 Min.
er. Force, 5 to 17 oz.
ease Force, 60 gram
. Life Ratings:
50,000 ops. @ 125/250 V. A.C., 2.5 AMP.
00,000 ops. @ 125/250 V. A.C., 5.0 AMP.
50,000 ops. @ 30 V. D.C., (2.5 AMP., IND.; 4.0 AMP., RES.)
b. Temp., —65° to +180° F.

Sealed in a corrosion-resistant, treated aluminum enclosure, this tiny switch is environment-free; highly vibration and shock resistant. It carries 5 amps. at 125/250 V.A.C. with an electrical life rating of 100,000 operations. Low operating force and small movement differential make it ideal for bi-metal temperature, diaphragm operated and other "feather-touch" devices, while small size permits mounting singly or ganged in restricted space. Rugged and dependable, it has positive snap action.

ny 40 amp. basic switch has high pacity, longer life and constant ability of tolerances

MODEL G3-8

asuring only 1¾" x 43/64" 5/64", the Electro-Snap G3-8 ic Switch handles current rat- up to 40 amps. A new hod of combining Electro- p's double-break action with eavy-duty switching element ires electrical and mechanical of 100,000 cycles at large acities; also provides constant stability of tolerances and accurate eatability. New plastic compound case gives the switch an am- nt temperature rating of —100° to +300° F. with extreme shock stance. Small size makes it ideal for motor controls and compact omation set-ups. A wide range of actuators is available.

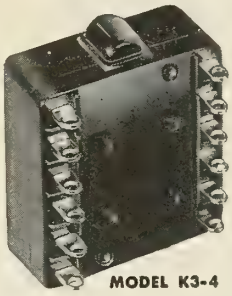
OPERATING CHARACTERISTICS

Single Pole, Double Throw
40 AMPS @ 125/250 V. A.C.
@ 30 V. D.C. Res.
Oper. Force, 45 oz. Approx.
Overtravel, .015" Min.
Move. Differ., .055 ± .010

ELECTRO SNAP

PRECISION SWITCHES

BASIC SWITCHES

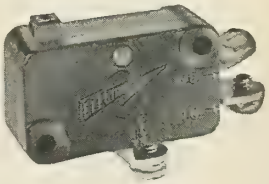


DIECAST ENCLOSED SWITCHES

HERMETICALLY SEALED LIMIT SWITCHES

CONFORM TO MIL & AN SPECIFICATIONS

Simultaneous triple-pole switch interrupts 3-phase ac. circuits; 6-circuit control in a small package



MODEL K3-4

Triple-Pole, Double Throw
15 AMP., 125/250 V. A.C.
30 V., D.C. Res.
10 AMP., 30 V., D.C., Ind.
Overtravel, .015 Min.
Move. Diff., .028 ± .007
Mech. Life, 1,000,000 ops.
Elec. Life, 500,000 ops.

This Electro-Snap triple-pole switch simultaneously reverses current flow through three windings of a 3-phase motor up to 1 H.P. and interrupts other types of multi-switching installations. Instantaneous "make" and "break" snap-action of the three poles is independent of the speed of actuation—even extremely slow moving cams can be used.

The K3-4 Series offers designers a wide variety of 3-phase circuit hookups for servo-controls, to limit movement of machine members and as a start-and-stop switch which formerly were possible only with complicated relays or a number of separate switches. A large selection of standard actuators is available.

Small basic switch is low cost; directly interchangeable with AN3234 Specs

F2 SERIES

These Electro-Snap F2 Series snap action switches are extra-compact with extremely high electrical capacity for their size. Mechanical and electrical life at 1/32" overtravel is 150,000 operations, minimum, with accurate repeatability and constant stability of tolerances. Self-aligning springs provide contact wiping action rare in a switch of this size.

Durable case of special plastic gives the switch an ambient temperature rating of —100° to +275° F. or +375° F. Available, *at low cost*, in three basic models with a wide selection of actuators.

SERIES F2 BASIC SWITCH: F2-3: Single Pole, Double Throw
F2-2: Single Pole, Normally Open; F2-1: Single Pole, Normally Closed

OPERATING CHARACTERISTICS

Electrical Rating: 10 AMP. 125/250 V. A.C. 60 cycles
30 V. D.C. inductive and resistive (6 AMP, 30 V. D.C. for Airborne Application)
Operating Force, 7 to 12 oz.
Reset Force, 4 oz. Min.
Pretravel, 3/64 Max.
Movement Differential, .011 ± .005
Overtravel, 1/32 Min.

CITY_____ ZONE____ STATE_____

Avco today

Avco's Crosley helps put a "Quartermaster" in the sky

Now, critical Air Force supplies cross the skies in greater bulk—with greater speed—via Lockheed's new C-130 Military Transport

To produce the all-important C-130 empennag (tail section), Lockheed called on Crosley. The result: empennages of consistent quality, and perfect interchangeability. Crosley's long experience with all methods of airframe toolin guarantees positive fidelity to design. Another contribution by Crosley Division at Avco.

THIS IS AVCO

Avco today is a diversified organization whose products include aircraft power plants and structures, electronics for defense and industry and specialized home and farm equipment. Avco's divisions and subsidiaries are:

Crosley—electronics and aircraft structures . . . Lycoming—aviation, marine and industrial power plants . . . American Kitchens . . . New Idea and Ezee Flow—specialized farm equipment . . . Research and Advanced Development . . . Crosley Broadcasting Corporation . . . Moffats, Ltd. (Canada)—commercial gas and heating equipment.

Scientists interested in unusual opportunities for advancement can grow with Avco.

Avco makes things better for America...

Adland Revisited

To the Editor:

It may come as a surprise to some of your readers that space is for sale and that a professional group of "space salesmen" exists. I don't, of course, refer to the kind of space that rockets are designed to overcome. I'm talking about the kind of space you were good enough to lend Mr. A. Swoboda last month for an auroral display of ignorance about advertising and the people who write it. Space salesmen of any publication will fail to confirm his assertions.

It's hard to be sensitive about stuff like his bit about "advertising writers suddenly becoming experts and dispensing hogwash," but I'll do my best. First of all, it would seem worse than futile to try to misinform technical men. And then, an advertisement is an important business investment. The people who invest in space, words and art in order to sell their products or services rarely care to see their money float away in hogwash.

Advertising men are not born very differently from other members of the human race, nor are they swaddled in grey flannel. Those I know are very hard working, unpretentious and competent people, with not even a sincere tie to distinguish them. While they may not be experts, they try to know all they can about the products they sell.

For myself, I have always had a soft spot for the guided missile, ever since I engaged in a years-long project for the evaluation of all missiles work done by Germany. It was my privilege and pleasure to translate a large chunk of the work on this subject done by the Russians. The fact that I now write advertising copy for a basic material which is indispensable in both guidance and plumbing systems may be entirely accidental. It would pain me to believe that similar accidents are not to be met with among advertising writers. Thanks for the space.

Andrew Certner
New York City, N.Y.

Coming Up

To the Editor:

As a British subscriber to m/r, may I congratulate you on a fine magazine. I wonder if we can look forward to an issue on missile control systems (hydraulic/pneumatic actuated etc.), sometime.

D. A. Parrish
18 Arundel Road
Hollywood
Worcestershire, England

We are planning an issue on missile components and subsystems to be published in May 1958.—Ed.

Historical Correction

To the Editor:

We were pleased to note your excellent summary of the *Dart* missile (m/r, July 1957, p. 128), for which the H. A. Wagner Co. has designed and developed the guidance system. However, one historical point should be corrected.

Your article indicates that although the Germans had made a few test firings of a wire-guided missile, "they did not have much luck." Actually, the wire command link was fully developed for speeds up to Mach .85. For use with two missiles, the HS-293 and the *Fritz X*, a large number of sets were supplied to the front should the Allies start to interfere with the radio link. Since the Germans never detected such interference, the wire link did not come into use.

Dr. H. A. Wagner, President
H. A. Wagner Co.
14707 Keswick St.
Van Nuys, Calif.

Repeat on Reprints

To the Editor:

I truly believe you have established your magazine as a leader in the field. I look forward to every issue.

You started something that you may not be able to stop in granting copies of m/r cover reprints. I want a color reprint of the July cover of the Be X-IE. I would also like a reprint of th very excellent First Annual Guided Mis sile Encyclopedia to give my supervisor There is nothing like it. I too want t echo another letter to the editor reques ing a coverage of *research* missiles in th encyclopedia. I have enjoyed so man articles in the magazine that I would no dare try to list them, but I do want t make special mention of Dr. Wernhe von Braun's article, "Space Travel and Ou Technological Revolution."

Horace S. Solliday
Douglas Aircraft Co.
2717 Carnegie La.
Redondo Beach, Calif.

Thank you. A color reprint is bein prepared for you. Also, reprints of vo

Circle No. 15 on Subscriber Service Card.

Braun's excellent article will be mailed to you as soon as we get them from the printer. (We had to go to a second printing.) Reprints of the encyclopedia are in the mail.—Ed.

Wants Second Helping

To the Editor:

Several weeks ago you were good enough to send me 12 copies of the Guided Missile Encyclopedia, reprinted from the July 1957 issue of m/r.

At the time I requested these I was aware that it was an excellent and very informative compilation. However, I must admit that I completely underestimated the degree of interest that it evoked among our people here. I find now that I need about a dozen additional copies to satisfy the requests from our sales and management staff.

I wonder if you can help me with another twelve reprints?

Murray Heyert

Avien, Inc.
58-15 Northern Blvd.
Woodside 77, New York

In the mail—Ed.

Rocket & Research Societies Invite Queries

To the Editor:

In response to Mr. L. F. Megow of the Rocket Research and Development Society of Houston, who requested information on launching facilities, the Pacific Rocket Society and Reaction Research Society have a firing range in the Mojave Desert about 130 miles northeast of Los Angeles. Our facilities include a concrete block house, several launching towers, a 2000 pound static test cell, and two tracking stations. It would be a pleasure to answer any inquiries by serious amateurs regarding our facilities or the activities in which the societies are engaged.

Robert A. Citron
Pacific Rocket Society
Northrop Aeronautical Institute Branch

1155 West Arbor Vitae St.
Inglewood 1, Calif.

Plaudits for Dr. von Braun

To the Editor:

We wholeheartedly agree that Dr. von Braun's "Space Travel and Our Technological Revolution," published in your July issue, is extremely well done.

I wonder if you could give us some idea of what 200 reprints would cost. The writer is chairman of Immanuel Lutheran Parent-Teachers' Society here in Kansas City and it is our idea to send a copy of this to each parent.

Fred C. Stebbins
Aviation Sales Manager
Puritan Compressed Gas Corp.

Kansas City, Mo.

The response to Dr. von Braun's article has been overwhelming. Unfortunately our supply of reprints has been exhausted. The second printing is in the works and your copies will be in the mails as soon as they are available.—Ed.

Amateur Missileer Stymied

To the Editor:

Received my first issue of m/r and was much pleased with its extended coverage in the rocket field. However, I understand from other subscribers that you have available an introductory issue composed of various subjects taken from past issues. This I would very much like to receive.

The question "Why doesn't American Rocket Society set up a missile launching base for amateur missileers," in Missile Miscellany, is one the undersigned and a lot of other people would like to have an answer to. I can name a hundred missileers who would give a month's pay to have a place to test their hardware.

Just in our small group on Project *Vanguard* we have home-built projects using anything from black powder to UDMH and from six inches to 16 feet. The big question is not EST etc., but where can we test and fire these jobs? We can't find the answer. Can you? We have a rocket ready to fire now employing as much range safety and tracking gear as *Vanguard* itself, but that doesn't give us permission to run the countdown. If you can give us any assistance toward a launch site, please do.

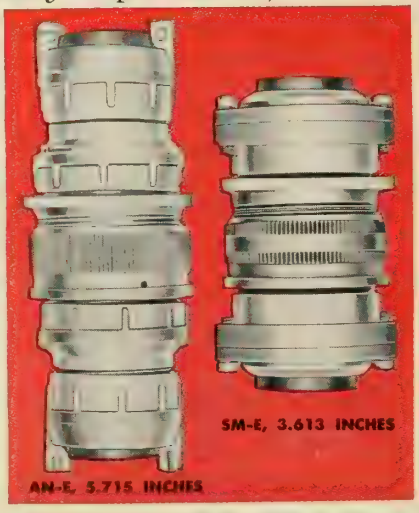
Harry R. Sampsey

31-48 78th St.
Jackson Heights, N.Y.

Try a local university. Also, consult Prof. S. Fred Singer, Physics Department, University of Maryland, College Park, Md. See Mr. Citron's letter, this page.—Ed.

New Bendix SM-E Connector

(smaller, lighter than AN-E but equally dependable)



Here is the newest in the ever growing family of Bendix* environment resistant connectors. The new SM-E Series (Short "E") will provide the same performance as the standard AN-E connectors, but is shorter, lighter and more easily serviced. Not only does this connector conform to the vibration resistant requirements of the "E" connector in the MIL-C-5015C government specification, but it also provides effective moisture barriers both at the solder well ends and mating surfaces using the full range of wire sizes. Of particular interest to production and maintenance people is the back nut design, which provides a jacking action on the grommet during disassembly, thereby lifting it free of the solder wells. This feature when combined with the new Bendix "slippery rubber" grommets makes easy work of wire threading and grommet travel over the wire bundles.

Available in all standard AN shell sizes and tooled for most of the popular AN configurations.

Write for complete descriptive folder.

*TRADEMARK

Comparison based on size 40 mated assemblies. Space savings for smaller sizes are proportional.

10 Mc Hycon Crystal Filter

HYCON EASTERN, INC.

75 CAMBRIDGE PARKWAY CAMBRIDGE 42, MASSACHUSETTS

To Designers of Aircraft and Missiles:

The July 24th issue of "The New York Times" described a new radio and radar component no larger than a cigarette lighter that simplifies the design of complicated electronic equipment. Known as the high frequency crystal filter, it is unaffected by abrupt temperature changes and repeated heavy shock and vibrations.

These units permit excellent reception in the presence of strong jamming or interfering signals. Maintenance is reduced to almost zero and alignment in the field is eliminated. Center frequencies are accurate to .001%. Insertion loss is 1/10 of other filtering methods. Aircraft and guided missile environmental requirements are exceeded.

Our Company has pioneered in the development of crystal filters. A number of standard models are currently in mass production. Many manufacturers of radio and radar equipment have developed improved systems utilizing Hycon Crystal Filters. It will pay you to ask your sub-contractors how this unique component can make your missiles or aircraft a more effective weapons system. If they are not familiar with the advantages of crystal filters, we can help you. A request on your company letterhead will receive a prompt reply.

MIRACLE IN MINIATURE

Observation and control of amphibious and airborne landings.

Close observation of jet or piston engine test performance.

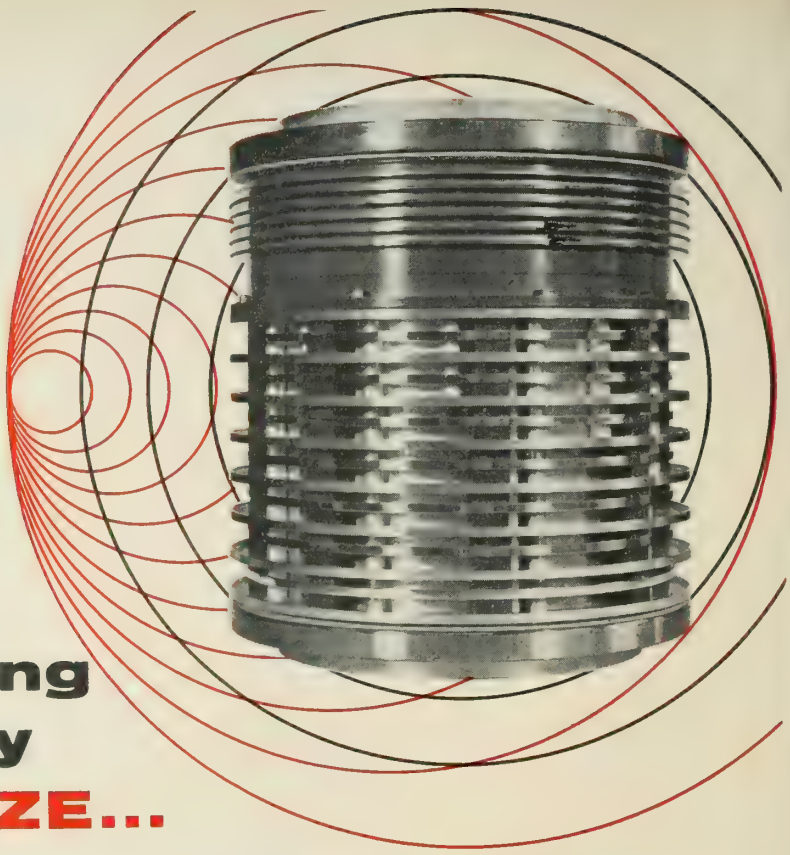
Surveillance of assembly areas and movements of forces.

Observation of danger areas, where exposure would involve danger to personnel.

Brand new! RCA "Telemite" (model JTV-1) a 1-pound ultra-miniature television camera, makes possible direct observation of sites and events never before accessible by TV

It fits lightly into the hand; it can be carried in a pocket; it weighs about a pound; it will go places too small for ordinary cameras, too dangerous for man; it will observe without being conspicuous; it may be mounted on a tripod, fastened to wall or bulkhead, hand-held by a pistol grip. Size: 1⅞" x 2⅜" x 4¾".

By means of a transistorized circuit and the new RCA half-inch Vidicon, the "Telemite" actually surpasses standard Vidicon-type industrial TV cameras in sensitivity. It produces clear, contrasty pictures with a scene illumination of 10-foot candles or less.



The "Telemite" operates with up to 200 feet of cable between it and the control monitor, and this distance can be further extended by using a repeater amplifier. This is the first TV camera to employ photoelectric sensitivity control, which provides automatic adaptation to widely varying scene illumination.

New 'SW' Rate Gyro

Simplicity delivers superior performance

Fundamental engineering and precision manufacturing team up to enable new Humphrey *SW* Rate Gyros to deliver superior performance. More rugged ... more dependable ... greater precision for the most demanding applications in advanced missile and aircraft systems.

Simplicity of design eliminates unnecessary parts. Heart of the *SW* Rate Gyro is the solid rotor inertial element mounted on precision radial thrust bearings in the exclusive bridge-like gimbal. Two unitized steel flexures give pivot and spring-restraint functions attaching gimbal to frame.

Using compatible materials and high-G centrifuge balancing adds to superior performance qualities. No deterioration of the *SW's* performance even under the most severe environmental conditions. Operates in temperatures from −65° F to ±185° F; vibration at 10G from 20 to 2,000 cps; and shock to 100G.

Four basic sizes provide choice of drive motors and pick-offs to avoid any compromise in your system design.

FOR COMPLETE SYSTEMS, SPECIFY HUMPHREY GYROSCOPES, ACCELEROMETERS, POTENTIOMETERS

Minimum number precision parts: solid rotor; exclusive coupling, flexures.

Simple sub-assembly: one compact unit; motor separate from sensing element.

Floating-piston constant-action dry-air damper; effective pressure-sealed case.

fast fuel transfer

FOR MISSILES

Modern Missile technology has developed a vast number of new fuels, each requiring special handling and storage. The problem of safely and quickly transferring these fuels from the storage areas to the missiles is one which requires special equipment. Fast Fuel Transfer systems (FFT), developed by Flight Refueling, Inc., to increase range and payload of airplanes, lend themselves admirably to these new applications.

The experience which Flight Refueling, Inc., has gained in research, design and production of the FFT systems used on modern military aircraft is already being applied to solve the complex problems of split-second preparation of missiles for operational use with greatest safety.

If you have a perplexing missile or aircraft fuel transfer problem, Flight Refueling's engineers will be pleased to discuss it with you and suggest methods of applying the proved FFT principles.

ATTENTION ENGINEERS

Unusual career opportunities for engineering personnel are available in new projects for developing new fuel transfer systems. Write Engineering Manager for details.

Kolcast Investment Castings

Missile bulkhead cast in
Timken alloy 17-22 at Kolcast.
Weight: 250 pounds.
Diameter: 30 inches.

this big...

can help cut your missile lead-time

This bulkhead for a missile is 30 inches in diameter, weighs 250 pounds. It was cast by Kolcast in high-strength, high-temperature alloy steel as an investment casting. It has not been machined!

As-cast surfaces, contours, and dimensions of Kolcast parts are so accurate that a minimum of surface metal has to be removed to prepare them for assembly.

The machining and finishing that you *don't* need to do on a Kolcast precision metal casting reduce costly alloy scrap and machine-hours on high-burden tools. Skilled man-hours and *time* are saved, too. Lead-time on jobs can often be reduced many weeks and sometimes months because of the operations eliminated on a Kolcast part.

Let our sales engineers show you case-histories on parts that have been designed and cast by Kolcast for leading manufacturers. Your engineers will find our designers helpful in changing over to Kolcast investment castings on parts weighing ounces or as much as 500 pounds.

Write on your company letterhead for the 16-page booklet which describes Kolcast parts and facilities. Ask for Booklet MR-10.

EXACT POSITIONING WITH MECHANICAL FEEDBACK IN NEW HIGH PERFORMANCE SERVO SYSTEM

Hydraulic Research's new integrated electro-hydraulic servo valve – actuator combination eliminates amplifier and electrical feedback by the addition of a mechanical feedback spring and increased servo valve gains.
This mechanical spring feedback loop provides a considerably lower time constant, and essentially infinite resolution. Also, greater reliability and lower costs result.

The unit illustrated above has a ¼" stroke with .16 watt electrical error input. It is in production. The design may be modified to any desired stroke, with inputs of .06 watts and lower. Hydraulic Research's new servo system design utilizes a basic dry coil torque motor servo valve. It is compact, lightweight, and adaptable to any application where precise positioning is required.

Developers and manufacturers of the "Hydomat"—compact multiple input servo package.

FLUORINE

For your missiles and rocketry program:

Elemental Fluorine
gas and liquid

Other oxidizers derived from Fluorine

Chlorine Trifluoride (ClF_3)
Bromine Pentafluoride (BrF_5)

GENERAL CHEMICAL – your prime source for Fluorine and its compounds

As America's primary producer of elemental fluorine, halogen fluorides and other fluorine compounds, General Chemical is geared to supply virtually any need—from tonnage requirements of fluorine to research or commercial quantities of many derivatives.

Of particular interest to you may be the ready availability of fluorine in *liquid* form. A break-through in fluorine technology pioneered by General Chemical now makes it possible for us to ship liquid fluorine in tonnage quantities . . . and for you to use it with greater safety and economy than ever before.

A special technical bulletin on fluorine (both gas and liquid) covering physical properties, storage and handling is available on request. Further information on it or other fluorine compounds of interest to you is available from any company office listed below.

• • •

General Chemical is also a major supplier of red and white fuming Nitric Acid so important in rocketry development programs. Complete data on request.

WHY DOUGLAS ENGINEERS AND SCIENTISTS GO FURTHER...
At DOUGLAS
...your
missiles assignment
can be as big as
your talents
Now in its 16th year, the Douglas missiles program is projected far into the future by such exciting new projects as THOR
Out of such veteran projects as Nike and Honest John are coming fantastic new missile systems to challenge the finest engineering talents in the land.
Since early in World War II, Douglas has been engaged in missile projects of prime importance. New engineering teams are constantly being formed for research, design, development and production. Engineers advance rapidly as Douglas expands its leadership in this challenging field.
You are stimulated to accelerate your career by the importance of each assignment ...by the help of your associates who are recognized experts in missile work... by the vastness of opportunity for engineers in this company that is run by engineers.
There is no more promising future than that which awaits you in the Douglas Missiles Divisions.
THOR—an intermediate range ballistics missile now under development—has top priority in our country's program for national defense.

Inter-Planetary Ballistic Missiles

IPBMs May Mean Safe H-bomb Tests

Build Inter-Planetary Ballistic Missiles and use the moon as a safe, profitable test site for H-bombs—this suggestion from Maryland University's Dr. S. Fred Singer at the Eighth Congress of the International Astronautical Federation in Barcelona, Spain, October 7-12. Dr. Singer is one of the original proposers of the *Far Side* space exploration rocket project now underway at Eniwetok.

As m/r goes to press, leading rocket, missile and space flight scientists, engineers, lawyers and editors from all over the Free and Communist worlds are meeting to read papers and discuss the latest state of the space-flight art—including everything from space law and moon rockets to IPBMs.

Dr. Singer, in a detailed technical paper, demonstrates the feasibility of testing missile-launched H-bombs on the moon. He insists that not only will this free the earth of any danger from radioactive fall out, but it will provide valuable scientific data as well. Some of the debris kicked up from blasting craters on the moon may result in dust particles and even boulders bombarding the earth. The latter would be large enough to be recovered pretty much intact. Study of these "moon samples" would provide valuable data on the history and current state of the solar system. Significantly, Dr. Singer suggests that nuclear bombs will soon become too big for safe testing on earth. "It is difficult to predict what will happen when we 'progress' to the point where a truly cosmic bomb can be produced, but since such a development is inevitable, we might as well face it."

Astrophysicist Singer argues that sending an IPBM to the moon 240,000 miles away will be no more of a technical problem than launching an ICBM 5000 miles. He points out that there will be a great weight-saving since it will need neither a heavy reentry nose cone nor such highly refined guidance as does the ICBM. The moon is an easier target than a city. He also notes that development of IPBMs is inevitable.

Advantages of this proposal include: "A good record of the power of the H-bomb for all to see;" lack of the need for expensive, space-consuming test ranges; less dependence on weather conditions for test shots; and new craters which will provide "unique opportunities for perpetuating the names of presidents, prime ministers and party secretaries." In addition, of course, there are numerous scientific benefits to be derived including the theories of meteor craters; study of meteoric-dust effects on the earth's weather; study of the motion of interplanetary gas with respect to the earth, study of magnetic and electrical phenomena, etc.

The moon missile's peak velocity would have to be 35,000 fps to escape the earth's gravitational field and fall into that of the moon. This is 40 per cent higher than satellite velocity. The point of light from an H-bomb flash on the sun would be twenty times as bright as a similar point of light on the moon. A 100-megaton bomb would blast a crater on the moon's surface 12,500 feet in diameter and 1800 feet deep. A 1000-megaton bomb would dig a hole 25,000 by 3000 feet. This compares to Clavius, the largest natural moon crater, which is 146 miles across and 16,100 feet deep.

Other papers at the Barcelona Congress include a treatise on space law by Andrew G. Haley who has been nominated as the next president of the IAF; and another by Darrell Romick on *Meteor Junior*—"A Preliminary Design Investigation of a Minimum-Sized Ferry Rocket Vehicle of the Meteor Concept."

Space lawyer Haley points out that even as space vehicles will bear little resemblance to their airborne, earth-bound cousins, so must whole new legal concepts be developed when "up" become "out" and when, eventually, living beings are found on other planets. Haley refers to his legal theories as metalaw.

Haley cites the self-evident fact that there is a difference between non-military, scientific satellites passing over some one else's sovereign territory—as will be the case with the IGY satellites—and a larger vehicle with direct military potential. He points out that we are on the verge of having to begin to think about the answers to these questions that will soon be critical in international, and interplanetary law. He also suggests next steps.

Rocketeer Romick presents in engineering detail a proposal for landing men on the moon's surface and getting them back again for a total cost of $30 million. Co-authors with Romick were Richard E. Knight and Samuel Black. All are with the Goodyear Aircraft Corp.

Navy *Polaris* Test Vehicle Fired

The first flight of the Navy's *Polaris* FBM was made from Cape Canaveral during the third week of September, and was described in an unconfirmed report as a "highly successful" flight.

Designated a test vehicle, it is believed to have been a two-stage configuration. Thiokol Chemical Corp. under contract with Army Ordnance is supplying full scale test missiles. Lockheed is prime contractor. Thiokol has a contract for at least six *Polaris* test vehicles.

The first stage consisted of two or more solid-propellant motors reported to be modified *Sergeant* surface-to-surface powerplants. The second stage, utilizing the latest principles in solid propellant development, was a single unit.

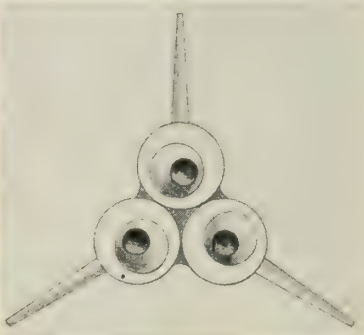
The new techniques employed in the second-stage motor of the *Polaris* test vehicle are considered a major breakthrough in the field of solid propellants. The motor exhausts into a high-pressure plenum chamber, which then directs the gas through four small nozzles. Four additional nozzles, spaced between the other four and turned to exhaust in the direction of missile travel, serve as pitch, yaw and nose-cone-separation control.

The ability to gimbal a solid-propellant motor has not been reported a state of the art. This leaves only two methods of control known to solid-propellant engineers—fins and venting. Fins are functional only when operating in the atmosphere. A *Polaris* FBM traveling 800-1500 miles would, during the later phase of its powered flight,

tough jobs in investment casting go to Arwood!

"Tough" Investment Casting jobs are the rule at ARWOOD, not the exception.

Intricate shapes, unusual contours, fine detail, metals and alloys difficult or impossible to machine, rigid quality control specifications, unyielding performance requirements . . . Add them all together and they total a "tough" job.



Expert research, design and development staffs, multi-plant tooling, casting and finish-machining facilities, Government-approved heat treating and inspection equipment, 54 field engineers in 20 major industrial centers . . . Add *them* all together and *they* total ARWOOD quality, reliability and know-how. More than a match for any "tough" job. Do YOU have one to try us out on?

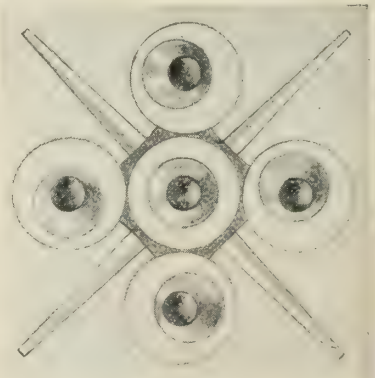
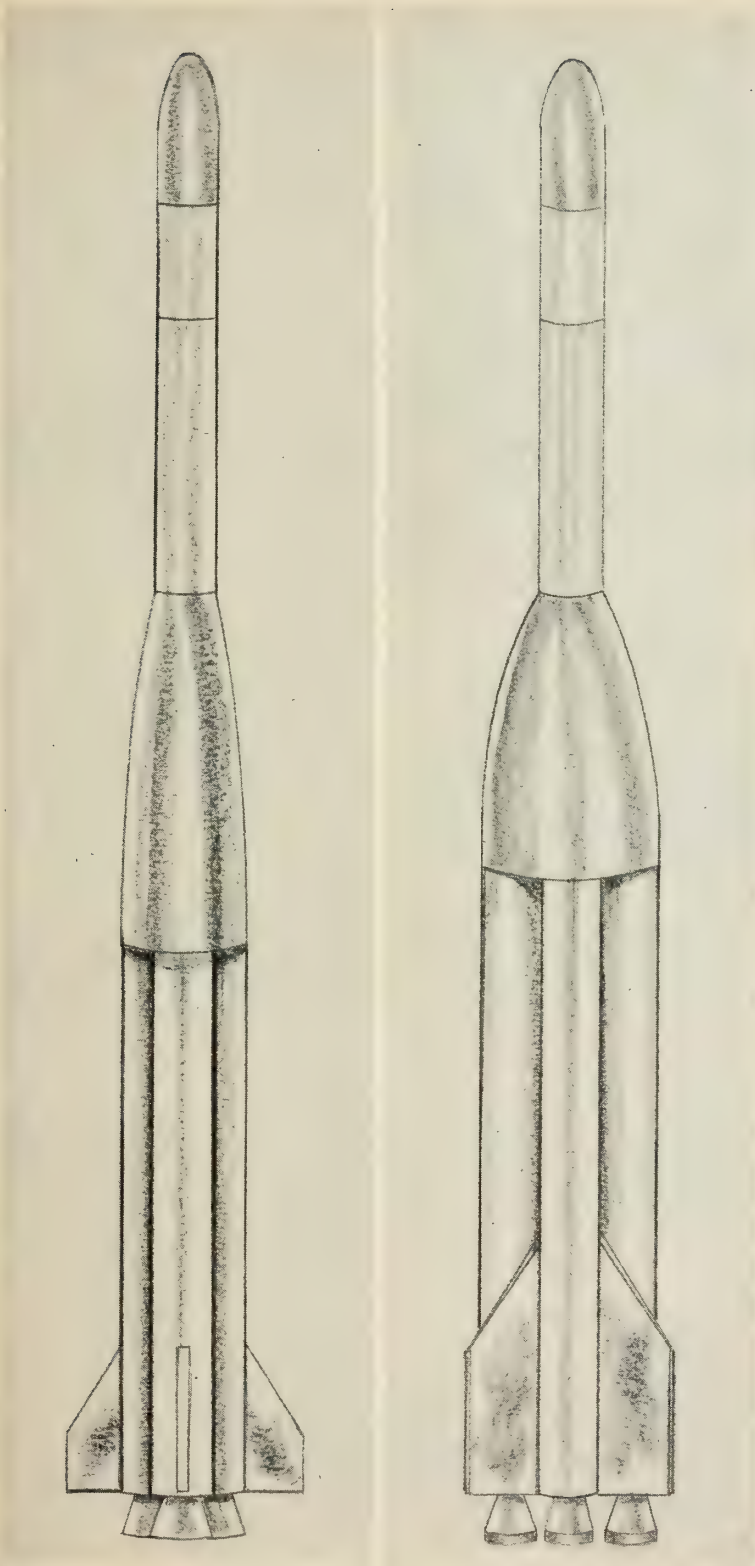
be operating at extreme altitudes above appreciable atmosphere. Therefore, a vented rocket system appears to be the only answer at this time.



Another major problem with solid-propellant rockets has been the decay of specific impulse and the inability to control precisely the velocity at burnout. This is a critical problem in ballistic missiles because the velocity at burnout determines the point of impact. Nozzles exhausting against the direction of travel will insure clean separation of the nose cone at the instant it is needed. Details of how such a missile

Aft view of possible arrangement of an 800-mile POLARIS test vehicle. Three solid-propellant rocket motors with canted nozzles arranged to impart spin during boost.



will be controlled in roll and the pitch and yaw plane of references is not known.

The *Polaris,* designed to be fired from submarines and surface ships, will necessarily have to use zero-length launch pads. For this reason the first stage will probably be fin- and spin-stabilized similar to the X-17. The

Aft view of the booster section of a possible arrangement for a 1500-mile POLARIS test missile. Center rocket could either be second stage of three-stage configuration or fifth booster rocket of possible two-stage model.

Polaris test vehicles are estimated to be four to six feet in diameter and 50 feet in length. Lockheed is currently using the X-17 on a separate *Polaris* test program.

Shown in an artist's conception are possible staging arrangements for the POLARIS test vehicles. Shown are an 800-mile test vehicle (left) and a 1500-mile version (right).

Snark Missile Squadron To Be Activated

Air Force has announced that the first *Snark* guided missile squadron will be activated late this year.

This will be the first intercontinental guided missile to come in to operational use. An aerodynamic cruise missile, it will travel at subsonic velocities.

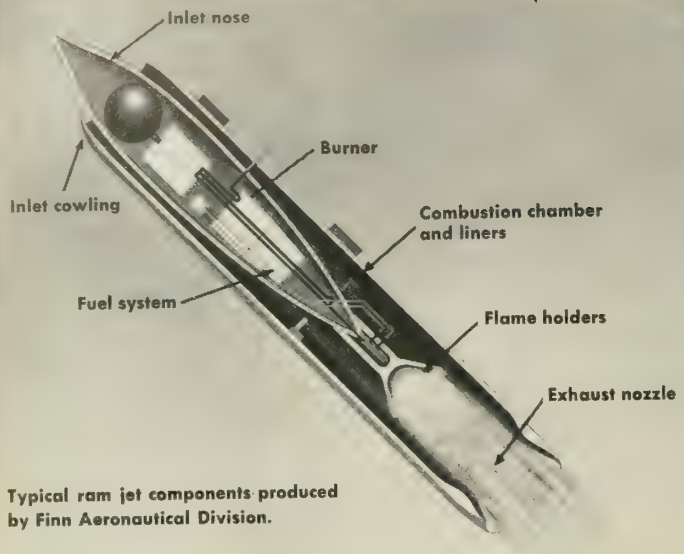
The squadron, to be assigned to the Strategic Air Command, will be equipped with the high-altitude, jet-propelled missile, which is capable of delivering a nuclear warhead.

The *Snark* SM-62, manufactured at the Northrop Division of Northrop Aircraft, Inc., at Hawthorne, Calif., is the first intercontinental missile to go into production for the Air Force.

Commander of the squadron will be Lt. Col. Richard W. Beck. Currently assigned to SAC's directorate of operations, Col. Beck formerly commanded a B-47 bombardment squadron at Lockbourne AFB, Ohio.

The exact site for the new missile unit has not been named at this time. SAC officials emphasized that missile units will be so positioned as to reduce problems of noise and to insure that missiles, if ever fired, will not pass over heavily populated regions.

Plans call for no missiles to be launched from operational sites except in case of war. For training purposes, missile crews will practice actual firing at an established range such as Patrick Air Force Base, Fla.



The missile squadron will be manned by some 500 officers and men. Personnel are now undergoing special training in the operation and maintenance of the *Snark* at Northrop's plant in Hawthorne.

Nike-Zeus On the Way

The U.S. Army Ordnance Corps is pushing hard on development of the *Nike-Zeus* system as a logical improvement of the up-and-coming *Nike-Hercules*. The *N-Z* would have a slant range of over 100 miles, be able to carry a nuclear warhead, and is to counter targets in the Mach 2, 50-75-thousand-foot altitude class.

Zeus would put the Army close on the heels of the Air Force *Bomarc* cruise missile. Thus, Ordnance Corps wants to progenerate the AAC by introducing a competing missile in the ground-to-air defense spectrum. In addition, there have been hints that *N-Z* could evolve into an anti-missile to counter the Soviet ballistic missiles.

Various designs for *N-Z* have

Typical ram jet components produced by Finn Aeronautical Division.

been leaving the drawing board at a fast rate while systems development is being carried out at Redestone Arsenal and other facilities. Indeed, some components are well beyond the drawing board and are entering the test phase.

Thiokol Has Tried Large Solid Rocket

Thiokol at Huntsville is said to have static-fired a large solid-propellant motor which may be the *Zeus*. The Army is known to favor an all-solid-propellant powerplant—possibly an ammonium nitrate-polysulfide formulation. The reason for this may be the rapidity with which Thiokol turned the *Hercules* design into production. It is felt that as soon as test firings and engineering analysis have been completed, the Army will push for adoption of this new weapon, claiming better reliability and lower cost than *Bomarc* and more versatility than *Hercules*.

Specification Breakdown

Speculators hint that *Zeus* may have the following makeup:

- Short-fat design to minimize center of gravity changes. This design would also facilitate handling and allow present equipment and storage facilities to be utilized with little modification. The large-diameter configuration would also allow the use of high-yield nuclear warheads for anti-missile use. An alternate design suggested uses the telephone-pole configuration.
- Single-stage, high-thrust motor, possibly with built-in program of high-thrust boost and lower-thrust level for cruise. Total burning time would be 30-60 seconds using an uncooled motor.
- Extensive use of lightweight alloys. Case bonded, internal-burning grain to permit high mass ratios. Protective insulation (burnaway liners, phenolic glass inserts, and Rokide-coated nozzle).
- Canted nozzles for spin-stabilization.
- Plenum chamber and combustion gas bleed to provide for auxiliary jet altitude control.
- Combustion cut-off achieved via cartridge-actuated vents to drop pressure and, hence, snuff out burning.
- Total loaded motor weight of two to four tons with motor volume of *Hermes* RV-A-10 proportions.

Since solid-propellant operation is expected, the system could probably be completed and ready for evaluation within a year. At this time, therefore, the Army can be expected to push hard for budgetary favors in getting *Nike-Zeus* into operation.

We specialize in precision welded sheet metal components for missiles, jets and ram jets

We have the experience, the equipment, the men and the approvals to carry out your most complex experimental welding and fabrication of jet, ram jet and missile engine components.

Some of the superalloys we've worked and welded include N-155...A-286...the Nimonics...Inconel-X...Inconel-W...Hastelloy...Timken...and stainless steel. Our welding department includes certified Sciaky spot welders, USAF certified heliarc welders and complete, USAF-approved X-ray facilities.

SOLVES RELAY ENVIRONMENTAL PROBLEMS

Unique Balanced-Armature Relays meet all requirements of the most exacting operating environments — shock, acceleration, vibration and high temperatures.

In the Leach Balanced-Armature Relay, shock and vibration forces cannot move the relay armature. This eliminates faulty operation of contacts during extreme vibration and acceleration.

These Leach Relays meet or exceed requirements of MIL-R-5757, MIL-R-6106, MIL-E-5272. Typical ratings include: vibration, 20 G's to 500 cps (higher ratings available); shock and acceleration, more than 50 G's; temperature, −50° to +125°C; life, 50,000 continuous operations minimum at rated load; available 28 vac, 115 vac, 400 cps operation. At right is Leach 9226, 1.49x1.49x 1.68 inches.

Leach has gained a unique reputation for creating reliable relays, *custom-tailored* to solve specific circuitry problems. Write for your copy of the Leach Balanced-Armature Relay Catalog.

Moon Cities Planned By Red Civil Defense Chief

N. A. Varvarov, chairman of the astronautical section of Russia's civil defense organization, has revealed plans for future Soviet cities which, he says, the government of the Soviet Union will build on the moon by early next century.

According to Comrade Varvarov, the future Red lunar city will have an artificial atmospheric pressure enabling humans from the earth to survive and even thrive on the moon. It will be a pressure one-third less than now present on the earth at sea level, but it will contain more oxygen so that man will be "able to breathe without any unpleasantness for his health."

The Red city will be built in one of the lunar craters, under a tremendous dome of glass and supplied with aluminum doors or "air-locks." Inside, at every half-mile or so, the city will be partitioned by glass walls with double doors. These will minimize the damage that may result from falling meteorites or other accidents.

"We will find it too expensive to carry food from the earth to the moon," says Varvarov. "A loaf of bread on being transported to the moon will be worth its weight in gold. Therefore, our future lunar settlements will have to be self-sufficient insofar as food is concerned."

Because of the difference in gravity, all plants will grow fantastically when transplanted to the moon: "A radish will be as tall as a date palm on earth; onions will send forth sprouts 33-feet long."

The Soviet man of the future will build on the moon a number of solar- and atom-energy stations, with the aid of which the moon's light, water, and other necessities will be furnished. Aluminum, glass, plastics, oxygen and nitrogen will all come from lunar ores.

But the main industry of the future Red lunar settlements as envisaged by Varvarov will be the manufacture of space ships and of fuel for such ships.

Jupiter-Thupiter-Thorpiter-Thor?

The operational future of the *Jupiter* is a matter of tremendous speculation as m/r goes to press. Its future lies in the hands of the special Committee on Missiles Study comprised of William H. Holaday, special aide to the Secretary of Defense for Guided Missiles, Maj. Gen. John B. Medaris of ABMA, and Maj. Gen. Benjamin A. Schriever of the Air Force.

The committee's function: study the merits of the *Jupiter* and *Thor* programs and recommend either one or a combination of both. The committee met on Sept. 26th for a ten-day session. Officials have expressed confidence that a decision will be reached by the middle of October.

The decision will of necessity be based on many parameters. Not the least will be politics. Also important is the performance record in the check-out labs and during static and flight tests at Cape Canaveral. The latter have been well publicized by alert, observant members of the press.

On the basis of flight duration, the *Jupiter* leads.

If the nation's IRBM evolves from an integration of the two missiles, the question is: what components of each will be used? Also, how long will this increase the missile's development time?

Much is known about the two missile systems. Enough information is available at least to convince the missile engineer that an arbitrary decision based on overoptimism could be detrimental and should be avoided at all costs.

The *Jupiter* is a finless constant-diameter cylinder topped with a bluff nose cone for housing its nuclear warhead (see drawing). It is slightly over 60 feet in length and nine feet in diameter. The tank section is entirely constructed of welded heavy gauge aluminum. The lower engine section is heavily reinforced with longitudinal stiffeners to overcome engine vibration.

The guidance and control package, located in a small section above the alcohol tank, is a product of the Ford Instrument Co., a division of Sperry-Rand. The guidance gyros are air-lubricated and were developed by ABMA and FICo. The anti-slosh device, developed and adopted after failure of the first two *Jupiter* tests, is the ultimate in simplicity. Developed at ABMA, it was included in a flight *Jupiter* six days after conception.

An outstanding achievement of the project is the small auxiliary power gas generator which has undergone extensive testing at ABMA's component test lab. The early V-2 problem of freezing LOX valves was still plaguing ABMA engineers during the development of the *Redstone* and in the early stages of the *Jupiter* program. All new valves are now subjected to a "bath" of LOX for long periods before acceptance. Throughout the *Jupiter* development program Chrysler Corp. engineers have worked side-by-side with ABMA personnel in order to achieve switchover to production status with a minimum delay. Reports are Chrysler can be in production within four months.

Radioplane XQ-4 (left) shown with the turboprop RP-77D drone and the RP-76 rocket drone.

Radioplane Drones Approach Flight Tests

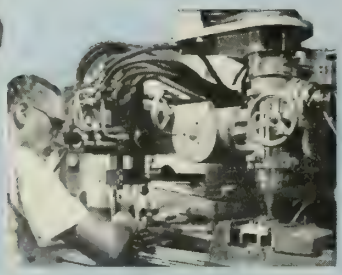
Radioplane is scheduled to reach the flight test stage on one of its most important target drone developments shortly after the first of the year.

Two vehicles are involved, the high-altitude, rocket-propelled RP-76 and the turboprop RP-77DL. The two are to be matched for air-launch in Radioplane's Oscura flight service project for the Army.

The project gets its name from the Oscura Range in New Mexico, where Radioplane is to provide integrated flight and maintenance services in connection with the Army training of personnel in surface-to-air missile firing.

The Oscura contract is considered a highly significant step forward in the services provided to the military establishment by private industry and quite a feather in Radioplane's cap. It is one of the first contracts to call for flight operation of target aircraft by an industrial team for missile firing trials. Under its terms, Radioplane provides not only aerial targets and ground support equipment, but flight operators, a training program and maintenance service.

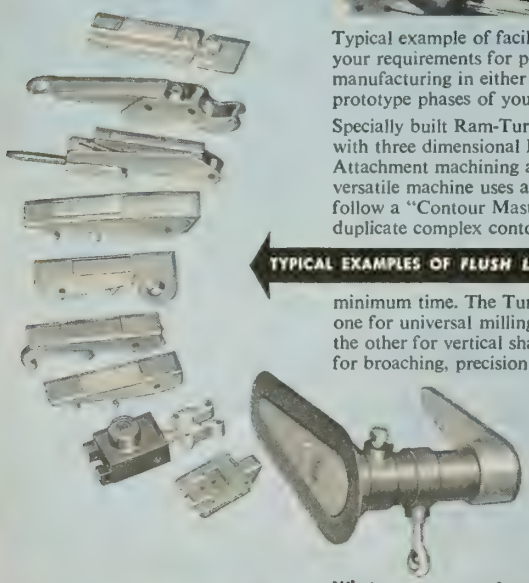
The final target drone will be the RP-76, a 300-pound plastic vehicle powered by an Aerojet 35-pound-thrust solid-propellant rocket motor. It will be carried aloft by the RP-77DL. The latter is powered by a Boeing 502-10E free turbine turboprop engine and is capable of 385 knots at 40,000 feet.



When a predetermined altitude is reached the RP-76 will be launched as a target for the *Nike* missile and the RP-77DL will be recovered by a parachute system. The RP-76 may also be recovered by the same method if it is not destroyed by the missile.

Both of the Oscura-project drones stem from Radioplane's RP-70, which was developed as a private enterprise with the company's own funds. A Navy version of the RP-76, called the XKD4R-1, has been delivered in evaluation quantities to Point Mugu. The RP-77DL is a later model of the RP-77D modified to carry a greater payload. Radioplane also is modifying the zero launcher designed for the RP-77D to permit attaching the RP-76 under the belly of the newer RP-77DL.

Lead time on the Oscura project is about 18 months, which means that actual operations on the *Nike* range will get under way about the first of 1959. Radioplane will establish headquarters for the project in El Paso, Texas.



PUT HARTWELL TO WORK
ON YOUR COMPLEX MECHANICAL COMPONENTS...

Typical example of facilities for meeting your requirements for precision manufacturing in either the production or prototype phases of your programs.

Specially built Ram-Turret Vertical Mill with three dimensional Hydraulic Attachment machining a component. This versatile machine uses a Tracer Stylus to follow a "Contour Master" and will duplicate complex contours and shapes in minimum time. The Turret has two heads; one for universal milling (any angle) and the other for vertical shaper attachment for broaching, precision serration, etc.

Missile Firings Accelerated at Cape Canaveral

The last days of summer at Cape Canaveral went out with the smoke and roar of rocket engines. The launching pads on the Cape were a beehive of activity as the Army, Navy and Air Force stepped up the pace of missile firings during September.

During this period the "grand stand" location of the beach watchers less than two miles north of the launching area was constantly occupied. Reports indicate that most of the firings were successful—good news for many projects.

The most sought-after and the most heavily financed missile in this country's arsenal, Convair's *Atlas* ICBM, rebelled and marred the impressive September firing record. In a firing that fell short of the performance by the *Atlas* flight in June, the missile was destroyed less than a mile above the launching pad.

As in the previous flight, only the booster engines were being tested. Descriptions of the *Atlas's* flight behavior indicate that the engines suffered a propellant-flow interruption with a resultant falling off of thrust. The merger of the two exhaust flames into a single billowing mass, as the missile discontinued its vertical ascent, is indicative of propellant-line rupture. If this is what happened, the *Atlas* probably destroyed itself before the safety officer could respond. Meanwhile, *Atlas* number three is being readied for firing in the near future.

The *Thor* IRBM, one of the most controversial missiles in missile history, apparently made its first successful flight. Description and photos of the missile indicate that it is similar in configuration to its competitor, the Army-developed Air Force *Jupiter*. Major visual difference is the addition of small triangular fins discernible in the launch photos.

Advance reports on the *Jupiter-Thor* decision say missiles will be "married." Gen. Schriever has said that the two missiles are basically identical. Engineers close to the projects tend to disagree with Schriever's statement. Principle difference, in addition to the fins on the *Thor*, is in body outline and guidance components. The *Thor* has a tapering body in contrast to the constant-diameter cylinder outline of the *Jupiter*. This could create a major bottleneck when combining the missiles.

A newcomer to Cape Canaveral was the Navy's *Polaris* FBM. A staged test vehicle built by Thiokol, its firing was reported a complete success (see page 37).

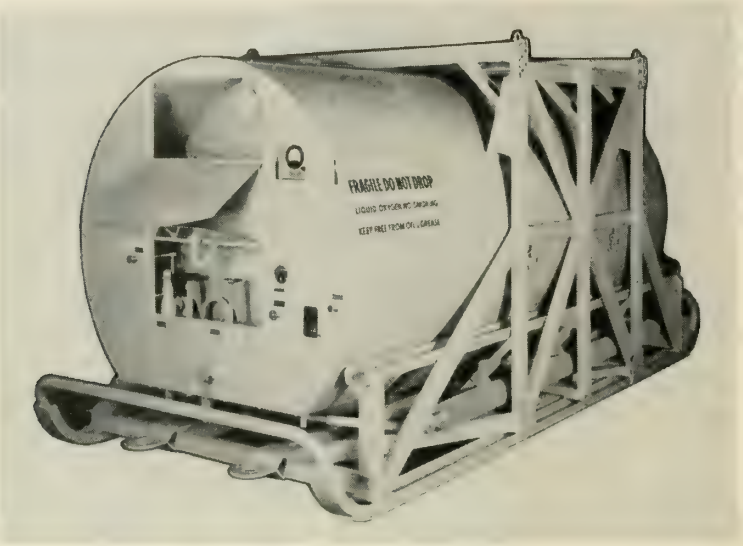
The *Navaho*, determined to make its death glorious and prolonged, had its second successful firing. Both flights have been made since the project was cancelled. Five *Navahos*, in varying stages of completion, were at NAA's plant when the project was slashed. The $15 million attributed to the phase-out of the project apparently is being well spent.

Adding impetus to the firing tempo, a *Snark* intercontinental cruise missile blasted from its zero-length launcher in a smooth climb. Shortly after dropping its solid-booster rockets, it disappeared into a cloud bank. Two jet chase planes followed the *Snark* in what may have been a successful flight. The *Snark* will be activated into operational squadrons before the end of the year.

The *Bomarc*, long-range surface-to-air missile, made a high-climbing long-distance intercept flight over the Atlantic after an unhampered launching. This was the first successful firing against a jet drone aircraft. The *Bomarc*, a regular visitor to Cape Canaveral, will soon start rolling through production assembly in Seattle.

The Army with its spectacular successes in the preceding months was slightly overshadowed during September with only a *Redstone* firing. At least two more firings of the *Jupiter* are expected in the weeks to come.

Good news for the IRBM program—Air Force THOR leaves pad in first successful flight. Taper of body and small fins can be seen.



Bad news for the ICBM program—Air Force ATLAS rises above pad at Cape Canaveral in second unsuccessful attempt. The two booster engines thrust the ATLAS skyward (left). At 5000 ft. it makes tilt to east, flame increases, and seconds later it explodes.

Army Activates First *Redstone* Group

HUNTSVILLE, Ala.—The Army's first heavy-missile group, equipped to use the 200-mile *Redstone* weapons system, was formally activated here on Sept. 18 under gray hurricane skies. It is the first unit to be fully equipped for combat use of the big missile developed here by Dr. Wernher von Braun and his team of former German scientists. It is the 40th Field Artillery Missile Group.

The backlash from Hurricane Esther held off long enough for an impressive ceremony, involving the 650 officers and men of the new group and a like number from Redstone Arsenal. to be carried out in the presence of the commander of the Army Ballistic Missile Agency, Maj. Gen. John B. Medaris, on the concrete airstrip of the Arsenal.

An unemphasized feature of the ceremony was the fact that five years of intensive research and development were required before this first armed *Redstone* missile group could become operational. But the historic significance was recognized far beyond the limits of this Southern city. The Associated Press sent a photographer because it had requests for pictures from as far away as Tokyo. All wire services, area dailies and television also covered.

For the 40th itself, the ceremony marked entry into a fourth dimension of warfare. Its unit colors have been carried into World Wars I & II, Korea and now into the age of missiles.

A REDSTONE missile, with frost forming on its skin from the liquid oxygen in the tanks, stands ready for launching. Note the logistical field support equipment that is now operational.

Parker Triple-lok fittings stand up under severest temperatures and stresses

Exhaustive tests by Parker and by missile builders prove that Triple-lok tube fittings stand up under the severest punishment of rocket stresses and strains, high pressures and temperatures . . . give you leakproof, dependable, *safe* connections.

Used on missiles and launching pads, Triple-lok fittings simplify construction, provide trouble-free connections, last longer. No matter how close the quarters, or how intricate the system, Triple-lok fittings are fast, easy to install.

Will even hold helium. Parker Triple-lok fittings can be furnished with specially treated flare nose surface that will trap even elusive helium, which no ordinary metal-to-metal seal can do.

The industrial standard. Triple-lok fittings come in a wide range of sizes and shapes (including *straight* threaded and *female* pipe threaded bodies). Available in type 316 stainless steel; in other alloys on special order. Warehouse stocks in all industrial centers. Ask your Parker Distributor for Triple-lok Catalog No. 4310, or write to —

"Liquid Oxygen" Replaces LOX Abbreviation in USAF

The Air Force is endeavoring to replace the abbreviation LOX with the words "liquid oxygen" where rocket fuels are concerned. The correction has been found necessary because of a conflict with the industrial designation LOX, which refers to liquid oxygen explosives.

The Air Force is undertaking the action to prevent dangerous and possibly disastrous results of the conflict. The term LOX will be deleted from all technical orders and directives, including reidentification of containers with the words spelled out, and the development of color coding for liquid oxygen containers, pipes and systems.

Thor-Jupiter Engine Now in Production

NEOSHO, Mo.—*Thor* engine production is underway at North American Aviation's $13.2-million Rocketdyne plant. The office and 228,000-square-foot facility was occupied in Feb. 1957. Ground on the 200-acre test site was broken a year ago and the large test stand is nearing completion and awaits its first firing.

Tests on the gas-generator units have already been made in the bank of special components test stands. LOX for the *Thor-Jupiter* engine will be trucked in from Tulsa, Okla.

The Neosho plant is located on 1785 acres of the northeast corner of Fort Crowder. The plant now employs about 720 workers with that figure expected to reach 800 by June of 1958. Despite the fact that start-up is just underway, things at Neosho have been described as quiet pending some sort of decision on the *Thor-Jupiter* IRBM.

Features of the plant include chemical milling facilities, a large center-of-thrust measuring jig, and water equipment for checking flow of plumbing, valves, and injectors.

The test facility was inherited from Aerojet, which designed it and had construction already underway when it was decided that North American was to operate the plant. Extensive earthworks are used to provide shelter for personnel and to ring the storage and test stand areas. The large vertical test stand uses a water-cooled steel flame-deflector. Work is nearing completion on the test stand and the instrumentation center is being fitted out with electronic recorders. First firing of the large stand is expected this fall and the first engine may be a hand model from Canoga Park, Calif., or the first prototype from Neosho.

THE ELIN DK-102 PRECISION POWER OSCILLATOR!

® Reg. U.S. Pat. Off. Pat. Pending.

For top precision performance in the oscillator field it's ēlin oscillators that can speed your results, save dollars! Ideal for pre-flight missile system checkouts, power source for all "bridge type" transducers, precision 400 cycle gyro testing, special power sources, time correlations, etc.—*wherever* you need "tuning fork" Frequency Stability, Absolute Voltage values, extremely low Output Impedance, Ultra-low Distortion and High Power Capacity!

The ēlin Precision Power Oscillator gives you all this through an exclusive High-Q LC tuned circuit and special voltage-sensitive bridge combined in a circuit employing a large amount of negative feedback.

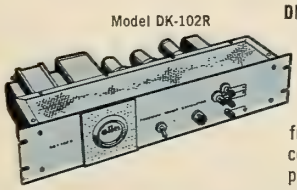
Standard model—2 watts power output (6 watt model, DK-106) at fixed audio frequencies between 250 to 15,000 cps. Special models available in higher power capacities and at other frequencies or to customer specifications. Write for literature TODAY!

SPECIFICATIONS:

FREQUENCY
250 CPS. to 15,000 CPS.

POWER
2 Watts (DK-102, DK-102R).
6 Watts (DK-106, DK-106R).

VOLTAGE
10, 30 & 100 volts RMS.
All with floating, center tapped output.



DISTORTION
0.1% maximum harmonic content
0.05% maximum AC hum
0.01% maximum noise

FREQUENCY STABILITY
±0.5% maximum, under usual lab ambient conditions.
±0.02% maximum, per ±10 volts variation in line voltage.
±0.05% maximum, zero to full load.

AMPLITUDE STABILITY
±0.1% maximum, under usual ambient conditions.
±0.02% maximum, per ±10 volts variation in line voltage.
±0.2% maximum, zero to full load.

PRICE: from $295.00

Model DK-102R

ELIN LEADS A "DOUBLE LIFE" of quick-change versatility providing fast modification from a DK-102 (cabinet model) to a DK-102R for rack mounting! All models are smartly styled, compact (5¾"H x 9"D x 16⅞"W) and built to give reliable, trouble-free service. 115V AC plug-in power is made to either lugs or AN adapter at rear of chassis!

Do you think of pressure transducers?

The Martin Company does...

and uses Statham Model PA183 pressure transducers in the SeaMaster program.

The Navy's P6M Martin SeaMaster is a 600-mile-per-hour pioneer aircraft of tomorrow's mobile seaplane striking forces.

The Model PA183 pressure transducer is available in ranges from 0-5 to 0-1,000 psi absolute with characteristics ideally suited to flight test. The transducing element is the rugged Statham unbonded strain gage. A feature of the design is that the case permits stacking one instrument upon another.

WHEN THE NEED IS TO KNOW...FOR SURE SPECIFY STATHAM

Underground Missile Factory Delayed

HUNTSVILLE, Ala.—The problem of getting a firm contract from the Army or another branch of the service is delaying the start of a much-discussed but still secret project for construction of an underground missile factory beneath a mountain here near the Army Ballistic Missile Agency and the vast Redstone Arsenal.

It is the so-called "Green Mountain" project, reportedly involving the Army, American Machine & Foundry Co., and Chemstone Corp. Green Mountain is a big ridge, several miles long, in the Blue Ridge chain that extends all the way from Virginia to middle Alabama. Its southern slope runs down to the Tennessee River. It is located just across Highway 231 from Redstone Arsenal. The project was first reported in m/r in earlier issues this year.

Original plans, according to reliable sources here, called for the excavation of thousands of tons of limestone from the mountain's innards to create a vast underground factory which was to be operated by AMF, presumably in conjunction with Redstone Arsenal and ABMA. There were also reports that a "junior Pentagon" for missile defense would be part of the project.

The project involved some complex problems from the beginning. There was the matter of excavating the mountain, converting the limestone taken out into lime and other chemical materials, providing methods of processing and shipping it, plus the purchase of the necessary real estate at reasonable prices and political maneuvering for construction of docks on the Tennessee River by the Alabama Dock Commission.

The land was acquired through some 600 purchases engineered through the Huntsville Industrial Expansion Committee, a group of public-spirited citizens. AMF put up the required money for these transactions and at length acquired full title to the necessary acreage. The State docks were obtained and construction is currently under way.

In its early stages, the project was apparently delayed when Maj. Gen. John B. Medaris, commander of the Army Ballistic Missile Agency, reportedly urged that Madkin Mountain, a smaller ridge situated on the Redstone reservation, be used. This apparently was resolved, and the decision made to go ahead with Green Mountain.

Then the Chemstone Corp. of Cleveland, Ohio, entered the picture. There were negotiations over a period of months, and agreement was purportedly reached for them to supply the facilities for excavation and processing of the rock, using Silas-Mason-Hangar, excavators of Hudson River tunnels, as a subcontractor.

As of late spring, the project seemed assured. At that point, the Army and the Air Force became involved in the *Jupiter-Thor* argument from which stemmed the sensational court-martial of Col. John C. Nickerson, Jr., of ABMA. The Wilson memorandum, assigning operational control of all missiles of more than 200 miles range to the Air Force, had also raised questions about the project.

At this stage, AMF, which is heavily engaged in development and manufacture of guided missile support equipment, control systems, ballistics, auxiliary power supplies and radar antennas, is said to be asking that the Defense Department, the Army or the Air Force make a firm contract for work to be done in the Green Mountain installation. The local leaders who have spurred the project are said to be urging AMF to go ahead with the project, then get a contract. Somewhere between these two positions is the fact that increased land values have already given AMF a profit of as much as $750,000 on the acreage as it now is situated. Also, it is reported that Chemstone and Silas-Mason-Hangar have lost original interest, and that another deal may be made with Flintkote Corp.

A decision on the project may be one result of the settlement of the *Jupiter-Thor* argument.

One Killed, Four Injured In Explosion at RMI

An explosion at RMI's Lake Denmark, N. J. facility recently killed one person and injured six others during a routine operation in the test stand. No engines were being run at the time and material damage was slight.

Killed was Herbert L. Bell, a representative of Chance Vought Aircraft. Most of the injuries were caused by flying metal and spraying propellant. An investigation is underway to determine the cause of the accident.

The RMI personnel injured are William Dellecker, Hjalmar Lagerquist, and Elmer Baierl. Chance Vought representatives injured are Glenn Repp. R. L. Johnson and R. D. Tweedy.

Washington Trends

By Erik Bergaust

WASHINGTON EXPECTS HIGH-ENERGY FUELS WILL DOUBLE boron demand in the next ten years. More boron is underway from U.S. Borax and Chemical Corp. The ore in the 80-million ton-load averages about 25% B_2O_3. Tailings could also yield lithium chemicals. Estimates of USB boron production is about 1-million tons per year. USB had been thinking of a "joint venture"—supposedly with Olin Mathieson—for boron research and production. Recently the boron firm announced that negotiations had broken off "by mutual consent."

PENTAGON IS TALKING ABOUT GOLD-PLATED REACTION ENGINES! Turbojets and possibly ramjets will get North American Aviation's "reflective coatings." Gold coats—thicknesses of 1/100,000 to 25/1,000,000 inch—are being sprayed on engine shrouds or on ceramic parts. The gold coating on the inside protects the engine from corrosion and heat. Rocketry went through this fad some years ago when it was fashionable to have the nozzle plated with gold, chromium, nickel, etc.

SENATOR STUART SYMINGTON (D-MO.) RECENTLY DECLARED Russia is "well ahead" of the U.S. in ICBM development and repeated charges that the Administration has cut back the ICBM program because of economy considerations. An effective anti-missile to ward off ICBMs is "at least ten years away," he said. "The idea that the anti-missile is around the corner, or only five years away, is absolutely false."

YOU ALSO HEAR PENTAGON OFFICIALS DISCUSS infrared counter measures: IRCM system that uses small heat-emitting rockets which can be launched from evading aircraft. Instead of a warhead, the IRCM rocket carries a flare or pyrotechnic (such as thermit) used in current *Sidewinder* tests. The attacking IR rocket will invariably (and wrongly) follow the smaller and higher-temperature flare. Meanwhile, solution-transistors may open an entirely new field in missile guidance. One expert visualizes a chemical system that can adjust to its environment (such as magnetic field, etc.), without outside help. Such systems could operate at high temperature without counter-measure-vulnerable electronics.

A SMALL BUT PROGRESSIVE FIRM ACROSS THE POTOMAC, Atlantic Research, put out a commercial solid-propellant strand burner some time ago. Recently a miniature mixer—for mixing small batches of new solid-propellant formulations—was introduced. Now Atlantic Research has come out with a small, commercial rocket motor. Its name is PET (Propulsion, Experimental Test) and it is being advocated for such sundry purposes as: testing small rockets, spinning larger rockets, acceleration of small masses, subjecting test materials to blast. PET delivers 40 lb. of thrust for one second from 0.213 lb. of "Arcite" composite propellant. It can be stored for 3 years. Ignition is achieved in a matter of milliseconds with a 6-volt dry cell.

GOVERNMENT OFFICIALS HAVE NO COMMENTS about recently reported atomic-rocket work in this country. A German newspaper recently claimed the U.S. is building atomic rockets. The German paper said Rocketdyne was building an atomic-powered missile which may well relegate Russian missiles to the scrap heap "in a very short time." Study contracts on atomic rockets have been let in this country, but we know of no atomic-powered missile in the prototype stage.

WASHINGTON'S NAVY MISSILEERS ARE ALL SMILES since the first *Polaris* test vehicle was successfully fired recently. Naval officials are understood to be working on a stepped-up schedule for atomic-powered subs for the *Polaris* (and for other possible FBMs expected to follow). Big problem is to synchronize missile and sub production so that the two weapons elements will be ready for each other in shortest possible time.

First Steps Taken to Form Missile Association

First steps have been taken to form a missile industries trade association. The first formative meeting was held September 23 in the Virginia Room of the Mayflower Hotel in Washington, D. C. A second is scheduled for October 22. It is expected that with this second meeting a trade association charter will be approved for incorporation.

Originally proposed as the National Industry Conference, NMIC, the organization's name has been changed to Associated Missiles and Rockets Industries, AMRI. Its basic purpose is to represent the interests of rockets, missiles, and space flight industries as a definitive group, including major prime systems contractors, major subsystems contractors and the various important subcontracting and components companies. A concerted effort is being made to bring together a representative cross-section for the October 22 meeting.

The September 23 meeting was attended by some 60 representatives (from about 30 companies) of industry and government. Companies present included: Northrop Aircraft, Inc., Cessna Aircraft Co., Raytheon Manufacturing Co., Aerojet-General Corp., Westinghouse Electric Corp., Ford Instrument Division of Sperry Rand, Thiokol Chemical Corp., Kaiser Industries, Harvey Industries, Haveg Industries, Inc., RCA, Atlantic Research Corp., Cook Development Corp., Aeronutronics Systems, Inc. (Ford Motor Co. subsidary), Cook Electric Co., and others.

The meeting was addressed by representatives from Army, Navy and Air Force concerned with missile budget, mobilization and production planning, who supported the need for such an organization. Attending as individuals were Vice Adm. Charles B. Momsen, USN (ret.), and Col. William O. Davis of the Air Force Office of Scientific Research. Both indicated they thought such an organization would provide a useful service to the missile industry.

Chairing the meeting was Kendall K. Hoyt, an old-time Washington, D. C. aviation consultant and former general manager of the National Aeronautic Association. He is acting as secretary of the proposed missile association.

A certificate of incorporation and a set of by-laws were presented to the September 23 meeting as working papers and as a means of indicating the nature and scope of the proposed organization. These working papers were drawn up free of charge by Andrew G. Haley, who personally feels that the organization should come into existence as long as it will not duplicate the services of the American Rocket Society, the Institute of Aeronautical Sciences and the Aircraft Industries Association.

The question was asked at the meeting: Who is behind this organization? No detailed answer to this was forthcoming. However, investigation reveals that the movement has been largely spontaneous, indicating a widespread feeling for the need of such an organization. From the way that the meeting proceeded, however, it seems fairly obvious that Diversey Engineering Co. is among the association's most enthusiastic supporters. Reports that an editor of Missiles & Rockets magazine agreed to act as a central contact point in the beginning are true. However, American Aviation Publications Inc.—m/r's publisher—points out that this was without authorization or knowledge of the company and that since before the September 23 meeting, no member of m/r's staff has participated in the promotion of the association.

The men who will decide whether it will be JUPITER or THOR—the Committee on Missile Study: Left to right—Maj. Gen. Medaris, William H. Holaday, and Maj. Gen. Schriever.

Red Satellite to Transmit On 40 Megacycles

The IGY satellite to be launched by the USSR will transmit on 40 mc instead of the 108 mc used by the *Vanguard* Satellite. It had been anticipated that the Soviet satellite's instrumentation would be compatible with the minitrack system but it now appears that tracking the Soviet sphere with western equipment will be impractical.

A description of Russia's satellite launching vehicle and launching program was cancelled because no member of their delegation was qualified to discuss the topic, the Reds said.

Methuselah's Speed Scorches Its Paint

Lockheed has announced that its X-7 ramjet missile, dubbed *Methuselah,* has been tested over Alamagordo and its speed was such that the missile's paint was scorched. *Methuselah,* a test vehicle for the *Bomarc* ramjet engine manufactured by Marquardt, was recovered intact by parachute. A solid-propellant rocket engine boosts the missile to speeds suitable for ramjet operation.

NACA Declassifies Exotic Rocket

CLEVELAND, Ohio—NACA has just declassified its exotic propellant work which was published in 1949. The work was done here at the Lewis Flight Propulsion Laboratory with liquid diborane and LOX in a 100-lb. thrust rocket engine.

Several runs were made in an uncooled motor (L*=325 in). Runs of about 6 seconds were made. In the runs, maximum specific impulse resulted at about 35% diborane and 65% LOX, and gave uncorrected values of about 249 lb-sec/lb. Corrected for heat rejection gave 274 sec. This latter value is about 92% theoretical (299 sec).

The fuel was 95% diborane and 5% ethane and ethyl ether. This mixture was estimated to give a performance some 2% lower than for pure diborane. Extensive solid deposit build-up was found in the chamber. Deposits were about 1/32 inch thick, crusty in nature with a smooth dark gray or brown glazed surface. NACA did not say what the deposits were but educated guesses are that it is probably boric oxide slag.

Because of the high heat releases, there were severe burnouts—especially in the nozzle and injector sections. Diborane proved remarkably stable when subjected to heat and shock tests. The boron compound could not be exploded or detonated. The boron work was carried out early in 1948 and probably started the ball rolling on carrying out more work with the boron fuels. Experimental details of the diborane-LOX rocket tests are reported in RM No. E9C11 and are available from NACA in Washington.

Dust May Affect ICBM Behavior

Experiments by Cornell Aeronautical Laboratory, Inc. have suggested that small amounts of dust in the atmosphere may markedly affect behavior of a missile such as the ICBM in re-entry from outer space.

CAL made the observation during research in its hypersonic shock tunnels, which operate at speeds as high as 15 times sound.

Engineers at the laboratory observed that during some tests, small particles of dust in the air were accelerated to high speeds and upon striking a blunt-nose model reflected from the surface back into the air stream.

Photographs were taken in CAL's hypersonic tunnels and showed that the wake of the reflected particles created a pointed cone in the air ahead of the model. Although it collapses almost immediately, this cone intersects and disrupts the shock wave that normally builds up in the air around the model's nose.

Such disturbances in the air flow may markedly affect aerodynamic behavior and, if small traces of dust existed in the atmosphere, could conceivably influence the flight of a high speed missile during re-entry from outer space. Such a condition might also affect the transfer of heat, a critical problem of re-entry.

The laboratory revealed these findings recently in a technical paper delivered at a meeting of the Advisory Group for Aeronautical Research and Development of the NATO nations, held in the Netherlands.

New Red Observatory

The Leningrad branch of the Institute of Earth Magnetism, Ionosphere, and Radio-Waves has revealed the opening of a newly built magnetic-variation observatory. The installation is located on the western shore of Lake Ladoga, "in an area remote from industrial establishments and transport, which precludes interference with observations."

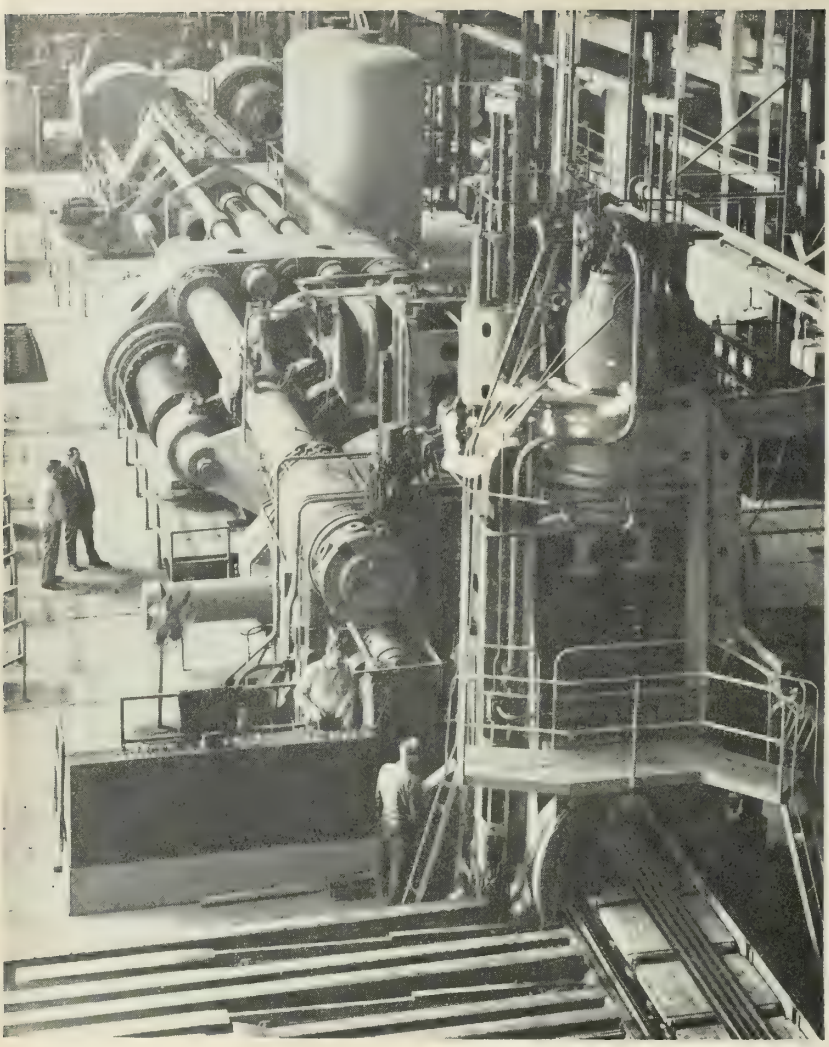
BURROUGHS ALWAYS NEEDS *Good* ENGINEERS

Man ... the First Computer

HE CANNOT DUPLICATE HIMSELF . . . BUT MAN HAS CREATED A FANTASTIC SERVANT . . .

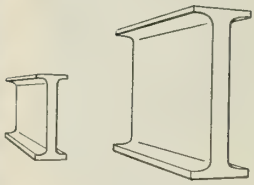
In a day when fascinating new computing concepts have swept scientific thought past all known barriers, it is easy to forget that behind all this amazing progress lies the one essential element for its success — MAN.

Although he creates computers and electronic brains that numb the imagination, the thinking man knows he is the first, and the most indispensable, of all computers. His genius at enslaving machinery to work with speed and accuracy surpassing his own is shown by today's electronic computers, which save man eons of time in solving problems recently considered hopelessly complex.



Solving many of these problems has enabled man to plan further accomplishments for his new electronic servant. In the future this remarkable assistant will handle languages as well as numbers; it will be capable of diagnosing and treating many illnesses; and, in industry, will actually "run" a plant. These are but a few instances of the computer's apparently limitless potential in a future restrained only by the boundaries of man's imagination.

Endowing computers with these near-human capacities is the special work of our talented creative teams at the Burroughs Research Center in Paoli, Pa. At this modern facility you can take part in our ambitious program, tackle new and refreshing assignments, guarantee your professional future and give your family the advantages of modern living in an established suburban community.



Our present needs are for people experienced in Electronic Digital Computers, Guided Missiles, Radar, Fire Control Systems and allied areas of electronics, with specific emphasis on men who by education or experience can qualify for the openings listed herein.

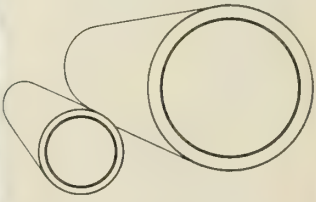
HOW THE 13,200-TON PRESS BOOSTS EXTRUSION CAPACITY



FROM 11″ TO 28″

STRUCTURAL SHAPES

FROM 9″ TO 20″

STIFFENED SECTIONS

FROM 10″ TO 24″ O. D.

TUBING

DOW'S NEW EXTRUSION PRESS PACKS 13,200-TON PUNCH

Here's a whole new range of large magnesium extrusions:
24-inch O. D. Tubing 28-inch I-Beams 80-foot-long sections

This mammoth press, newest addition to The Dow Chemical Company's rolling and extrusion mill at Madison, Illinois, is the world's largest magnesium extrusion facility. Its vastly increased capacities afford new opportunities for designers working with light metals. A wide variety of new magnesium applications for aircraft, missile, military and general industrial use are now possible and practical. In addition to extruding magnesium, the press is also available for large aluminum extrusions.

Here's how the big press will increase maximum dimensions of representative magnesium extrusions: Integrally stiffened sections, from 9 to 20 inches wide; I-Beams from 11 to 28 inches high; round tubing from 10 to 24 inches outside diameter; and maximum lengths of 80 feet. A large number of shapes and forms can be produced, limited only by the design of the die through which the metal is extruded. Many complex shapes that formerly required separate operations can now be formed in one operation.

If your design calls for large magnesium or aluminum extrusions, contact the nearest Dow Sales Office or write to THE DOW CHEMICAL COMPANY, Midland, Michigan, Department MA 1406G.

AF-Army-Ford Rocket Cracks Shell

In a dramatic demonstration of how much can be done for how little money when inter-service rivalries are set aside in favor of getting on with the job at hand, Air Force Office of Scientific Research's *Far Side* will soon streak to a record-breaking altitude of some 4000 miles.

Delayed by fringe weather conditions from typhoon Faye, AF is poised, ready and waiting to loose its giant helium-filled balloon into the stratosphere. Two hours later at 100,000 feet a 10-rocket, four-stage vehicle will blast loose. Within moments "up" will become "out," and man will crack the atmospheric shell that binds him to the egg called earth.

Carrying an instrumental payload weighing three-and-a-half pounds, this shot is the first of six planned in the current *Far Side* series. The basic configuration, however, with but slight modification is capable of landing dye-markers, flares or other payloads on the moon.

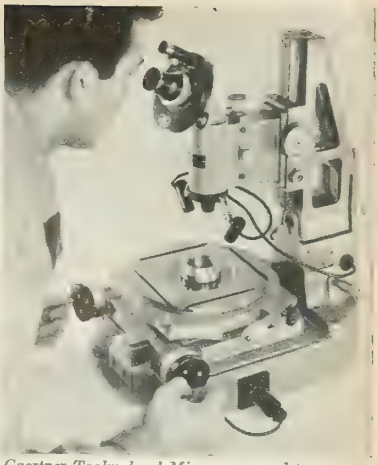
The prime contractor on the project is Aeronutronics Systems, Inc., a Ford Motor Co. subsidiary. The vehicle uses five Thiokol Chemical Co. *Recruit* and five Grand Central Rocket Co. *Arrow II* (developed *Loki*) rockets, all developed with Army Funds. The original proposal was made by Dr. S. Fred Singer of the University of Maryland's Physics Department. Dr. Singer is also supplying some of the instrumentation.

During September it looked as though the project might have to be dropped due to nondiscriminatory across-the-board slashes in allowable expenditures for the first six months of fiscal 1958. AFOSR's budget, however, has been completely reinstated.

One of the most dramatic aspects of *Far Side* is the amount of research gained for the dollars expended. AFOSR has put approximately $800,000 into *Far Side*. Aeronautics has added about $400,000 of its own funds.

While the firing is largely non-directional—aimed straight up—the vehicle spends a considerable time above the earth's atmosphere, taking something over two hours to make the complete "out-in" circuit. During all this time sensing elements are measuring space conditions which are telemetered back to earth.

Rocketeer Blackmon Does it Anyway



Unencumbered by interservice rivalries, budget limitations and the engineering shortage, Rocketeer Jimmy Blackmon fired his second rocket last month.

The eighteen-year-old rocket expert, whose first rocket never got off the ground due to extra-heavy governmental red tape and too much backpressure, took his second model to a deserted North Carolina beach and launched it with the aid of some friends. He didn't make the mistake of asking the government for clearance this time.

Using a propellant of powder zinc and sulphur, ignited by an automobile battery, the 5½-foot-long vehicle zoomed to 4000 feet at great speed and then fell into the ocean about 400 feet from the launching site.

Unimpressive beginning for a very dramatic event. Thiokol RECRUIT rockets are loaded aboard a DC-7 for shipment to Eniwetok Atoll in the Marshall Islands where they will be staged as FAR SIDE vehicles. Six launchings will be made before first phase of the program is completed. Aeronutronics Systems, Inc., and AFOSR are conducting the tests.

Gaertner Toolmakers' Microscope used to measure typical piece part. Co-ordinate range 4" x 2".

Precise measurement to 0.0001" and 1 min. of arc

Gaertner Toolmakers' Microscope

Here is a reliable, easy-to-use microscope for precise measurement of piece parts, tools, dies, thread gages, templates, jigs, fixtures, etc. Ideally suited for making a wide variety of precision measurements and is especially valuable in reducing rejects in production work.

With the Gaertner Toolmakers' Microscope you make direct, non-destructive measurements — no contact, no distortion, images are sharp and clear. It is a basic measuring instrument for inspection depts., gage labs, tool and die and model shops, industrial and research labs.

The Gaertner Toolmakers' Microscope has been proven in use by U. S. Government Gage Laboratories, and by prime contractors and their subcontractors. With all parties using the same measuring instrument, inspection procedures are co-ordinated and disagreements and rejects minimized.

Features that help you get
HIGH SETTING AND REPEATING ACCURACY

- Low, compact built-in rotary stage reads to 1 minute of arc throughout 360° range.
- Minimum overhang of stages.
- Full 2" precision-lapped lead screws with correction device.
- Straightforward, direct, uncomplicated optical system.

Features that assure you of
EASY, CONVENIENT OPERATION

- Independently rotatable cross hairs in protractor ocular speed up measurements, simplify measuring procedure.
- Convenient location of ocular eyepieces for ease of reading.
- Built-in transformer and plugs for all illuminators.

Modifications and accessories to
MEET YOUR EXACT REQUIREMENTS

- Thread and radius templates, camera and spotting attachments, fine motion focus, variable magnification available.
- If you have a special measuring problem, our staff of representatives will be happy to consult with you. The service and engineering facilities of the manufacturer are always immediately available to help you.

Where Miles are Measured in Thousandths of an Inch

As ballistic missiles go farther and faster, weight becomes an increasingly critical problem. Walls of rocket cases, for example, must be still stronger to withstand higher pressures, yet still thinner to cut "hardware" poundage to a minimum.

Obtaining optimum wall thinness throughout in rockets now being developed is one of M. W. Kellogg's current defense assignments. It is a complex engineering task and demands a highly specialized knowledge of metallurgy, metal fatigue, heat transfer, corrosion, weight-strength relationships, and welding techniques.

The M. W. Kellogg Company has been closely associated with the development and fabrication of rocket cases and components since 1947. Inquiries are invited from organizations wishing to put Kellogg's specialized background to work on specific problems.

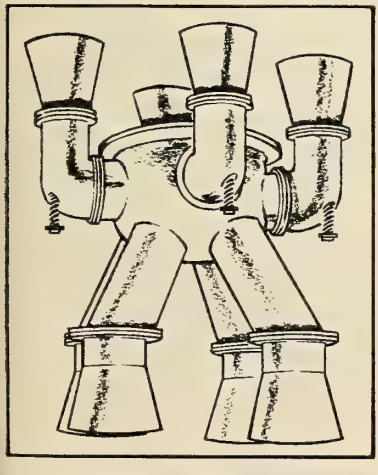
Nike-Hercules Missile Nears Operational Status

FORT TOTTEN, N. Y.—The Army proudly displayed the *Nike-Hercules*, its latest addition to the Continental Air Defense system, during the most complete rundown to date of the Army's role in air defense.

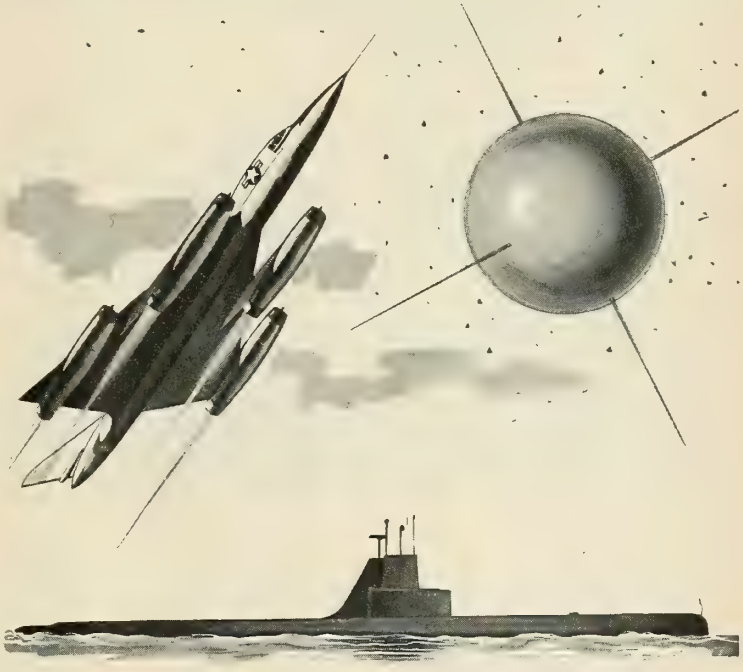
An improved member of the *Nike* family, *Nike-Hercules,* originally designated *Nike B,* is currently undergoing final tests. It is expected to be integrated into existing *Nike* batteries as a supplement to the *Nike-Ajax* within the next year.

Nike-Hercules was reported to have a range more than twice the *Ajax*—approximately 70-75 miles—and 25 per cent higher altitude capability. Its greater velocity and the increased lethality of its atomic warhead will make it one of the nation's most deadly surface-to-air missiles.



The five-ton, 39-foot missile has solid-propellant boosters and sustainer. Booster is a cluster of four *Ajax* while sustainer is a radical development in solid-propellant motors (see Industry Spotlight p. 145).

The sustainer motor is unique in that the exhaust nozzle is located at the end of a long constant-diameter tube extending from the combustion chamber. This design was motivated by the need to shift the center of gravity of the *Hercules* forward. Pitch, yaw and roll control system is located around the exhaust tube. A single solid-booster motor is currently under development. This will increase the mass ratio and specific impulse of the present four-barreled system.



Present defense cutbacks will not slow down the *Hercules* program. Modification of existing sites will be needed before the *Nike-Hercules* can be integrated. Exact modification costs were not known although partial figures indicate costs will be high. Modifications, including new launchers and assembly buildings, will be approximately $40,000 for each site. In addition, a new universal fire control console costing one-half-million dollars will be needed. *Ajax* consoles will be modified.

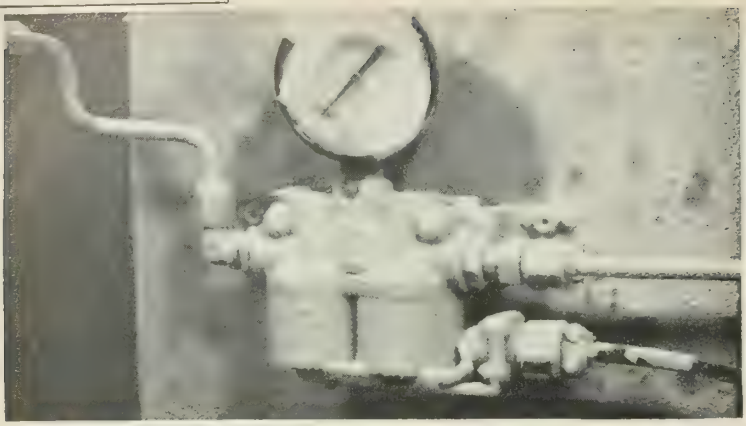
Army officials announced that present *Nike-Hercules* models cost approximately $15,000, while each mission with an atomic warhead could cost up to $1 million.

Next addition to the family will be the *Nike-Zeus.* Two models are under development: an anti-missile missile and an intermediate range version. The Army, restricted to point defense, might infringe upon the area defense mission.

This plenum chamber with eight nozzles shows how some of the solid-propellant thinking is going at Thiokol Chemical Co. Four reversing nozzles could be used for either pitch and yaw control, clean separation or both.

We may have already solved your flexible ducting problem

Flexible's been solving tough ducting problems in many different fields for a great many years. And has engineered all kinds of special shapes and tubings in a wide variety of fabrics and coatings for unusual applications . . . a starter duct for jet aircraft, for example, as well as special ductings used in the missile field for ground support. So it could be that we already have the answer to your particular problem. If not, we'll put our research facilities, including our brand-new laboratory, to work immediately. If silicone ducting is called for, our special Silicone Department, working with automated machinery, is prepared to meet your specifications.



To find out how Flexible can solve your ducting problems, write us, outlining your requirements. Our engineers will be glad to put their experience to work for you. Write to Dept. 210.

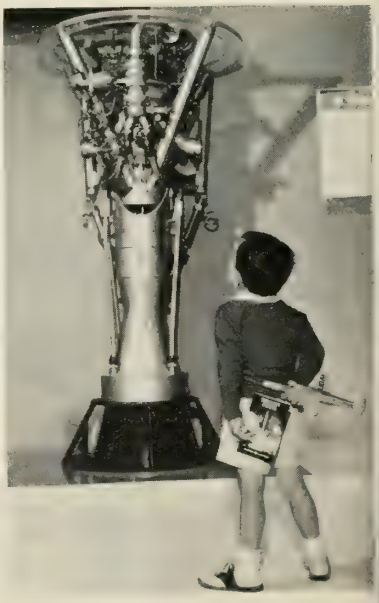
Explosion Waves Studied



The Air Force is using high-speed photography in attempts to tame explosions and put them to use for propulsion. The ARDC hopes to learn enough about the detonation waves to suggest ways to control them. The research could conceivably lead to the development of smaller and lighter engines.

In order to photograph the waves for study, the AF is utilizing a Beckman & Whitley ultra-speed framing camera that shoots 25 individual photographs in 1/15,000th of a second as the waves pass an eight-inch window in the 25-foot test chamber.

Deserves a Silly Answer*

Seeking reasons for the presence of Dr. Ramo, America's "top guided-missile man" in this country, the News Chronicle diarist got a "Don't know" from the Ministry of Defence, a "Here on pleasure" from the U.S. Embassy and a "Strictly business" from the visitor himself, while British guided weapons spokesmen countered with "Who is Dr. Ramo?" and "How do you spell it?" and the diarist had to end a promising paragraph with, "Maybe he is just admiring the beauties of nature." This had all the others wishing they'd thought of that one at the time.

**Reprinted with permission of PUNCH.*

Afterburner Cooling Assembly Gangs Straight Wall Tubing For High Strength, Light Weight

A minimum weight plus complex fabricating problems were critical factors in the development of this afterburner cooling blast tube assembly.

The space envelope was shallow and wide and over six feet long. The assembly was required to be tested at 28 psig with collapsing pressure of −2.5 psig and at a temperature of 250° F.

Flexonics answered the need by

End view of afterburner cooling assembly. Note rectangular shape of ends.

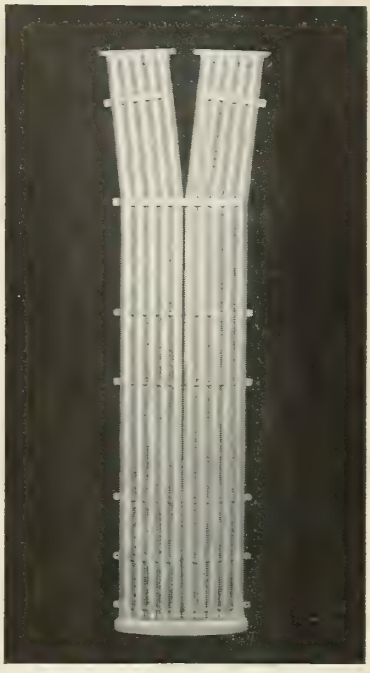
forming standard High Strength welded tubing into a gang. Ends of the tubes were formed to a rectangular shape to adapt them to the required end fittings. The tubes are held together with welded bands as the illustration of the unit shows. Tabs are provided for mounting in the airframe.

Tubing used in the assembly is 1.625″ O.D. by .011″ wall thickness. Type 321 High Strength stainless steel is used, with ultimate of 100,000 psi.

Facilities are the Key Factor

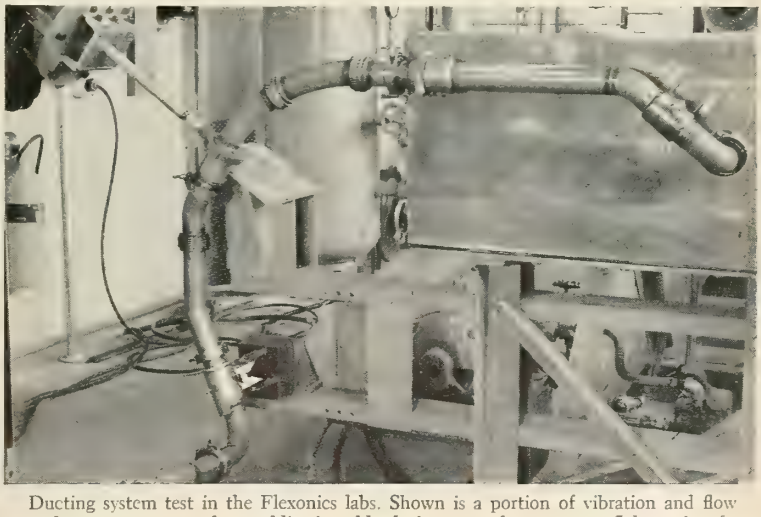
In the engineering, fabrication and proving of assemblies such as this, facilities are all important. As the pioneer and leading manufacturer of light weight corrosion resistant flexible assemblies and ducting, Flexonics Corporation has facilities second to none.

The engineering skill of Flexonics Corporation is proved by the scores of developments already made ranging from single flex connectors to entire aircraft ducting systems.



The manufacturing know-how of Flexonics Corporation is proved by the daily trouble free production of intricate assemblies and by such developments as the re-deposition process of forming ducting components.

The ability to prove assemblies before their installation in aircraft and engines is assured by the extensive Flexonics laboratories capable of the most advanced testing procedures.



Engineering Assistance

Whenever you have a problem involving aircraft plumbing, take advantage of the know-how and facilities of Flexonics Corporation. For specific recommendations send an outline of your requirements.

For help right at your desk, write for information on how qualified persons can secure copies of the new Flexonics Engineering Manual.

Complete afterburner cooling assembly. Note use of straps to gang the tubing.

Ducting system test in the Flexonics labs. Shown is a portion of vibration and flow under pressure tests of assemblies in a bleed air system for a current fighter aircraft.

NOW, FROM FLEXONICS A COMPLETE LINE OF FLEXIBLE CONNECTORS AND DUCTING

With the acquisition of FLEX-O-TUBE Division, Flexonics Corporation is now able to offer a complete line of rubber, synthetic and Teflon hose assemblies and crimped-on and re-usable fittings. Write for full information.

Behind the Curtain

by Dr. Albert Parry

Moscow's announcement of the first successful Soviet ICBM test was clearly meant as a threat to us. Do the Soviets know that the threat will only spur us on with our ICBM work? They do. They must feel they have no choice but to brag and threaten. And not only for foreign policy reasons (to queer the disarmament talks; to stop us from doing something about the Syrian mess; to intimidate the UN in the Hungarian debate), but also because of their domestic unrest—particularly the Soviet and satellite youth. Nikita may be saying to his Kremlin colleagues: "Let's make our youths forget their restless cynicism by a bit of ICBM-rattling. Let's make them patriotic and proud about Communism again by telling them we are ahead of America in the ultimate weapon."

•

Russia does not yet have a model of her artificial satellite. Her scientists haven't as yet decided on the size and weight of those Red moons. So said Dr. Valeria Troitskaya, general secretary of the Soviet IGY Committee, on her visit to Toronto. Russia does not yet have rockets ready to launch artificial satellites, declared Dr. Vladimir Kotelnikov while heading a 16-man Soviet delegation to San Francisco's Western Electronics Show and Convention. And this man ought to know. He is chief of the Radio and Electronics Division of the Soviet Academy of Sciences.

Yet, from Leningrad, comes the contradictory news that the Main Astronomical Observatory of the same Academy has begun its final intensive preparations to watch the Soviet satellites once they are launched: 30 special "spyglasses" are being installed on as many platforms at Pulkovo, and teams of observers are being formed under the command of D. Shchegolev, described as "candidate of physico-mathematical sciences." This may suggest that, Drs. Troitskaya and Kotelnikov to the contrary notwithstanding, the Red moment of launching is near.

•

Soviet scientists have lately shown a marked interest in whatever U.S. and West European reports they can find on American research experiments with "weightless airplanes." In the Moscow KOMSOMOLSKAYA PRAVDA young Russian physicist P. Nikitin quotes a West German aviation magazine to the effect that eight commercial American concerns and seven American universities and technical colleges are working on the problem of gravitation and how to defy it by building and flying "nonweight aircraft." According to Nikitin, anti-gravitation forces once invoked "will be sufficient even for interplanetary flying apparatuses." The Soviet scientist calls special attention to "a news item published in AMERICAN AVIATION saying that Avro, a Canadian firm, has begun the construction of a flying disc which will rise vertically" as proof that gravity-defying flights may soon be possible.

The 1957 program of the Soviet State "Foreign Literature" Publishing House includes publication of a book entitled EXPLORATION OF THE UPPER ATMOSPHERE BY ROCKETS, a Russian translation, apparently, from English.

Long Range Planning and Research at Marquardt...

by
Roy E. Marquardt
President

Although ramjet development in the Powerplants Division is the major activity here at Marquardt, there are three other divisions carrying on significant work; Controls and Accessories, Test, and Long Range Planning and Research.

The youngest of these Divisions is Long Range Planning and Research. Headed by John Drake, and numbering 50 engineers, the Division has two primary functions:

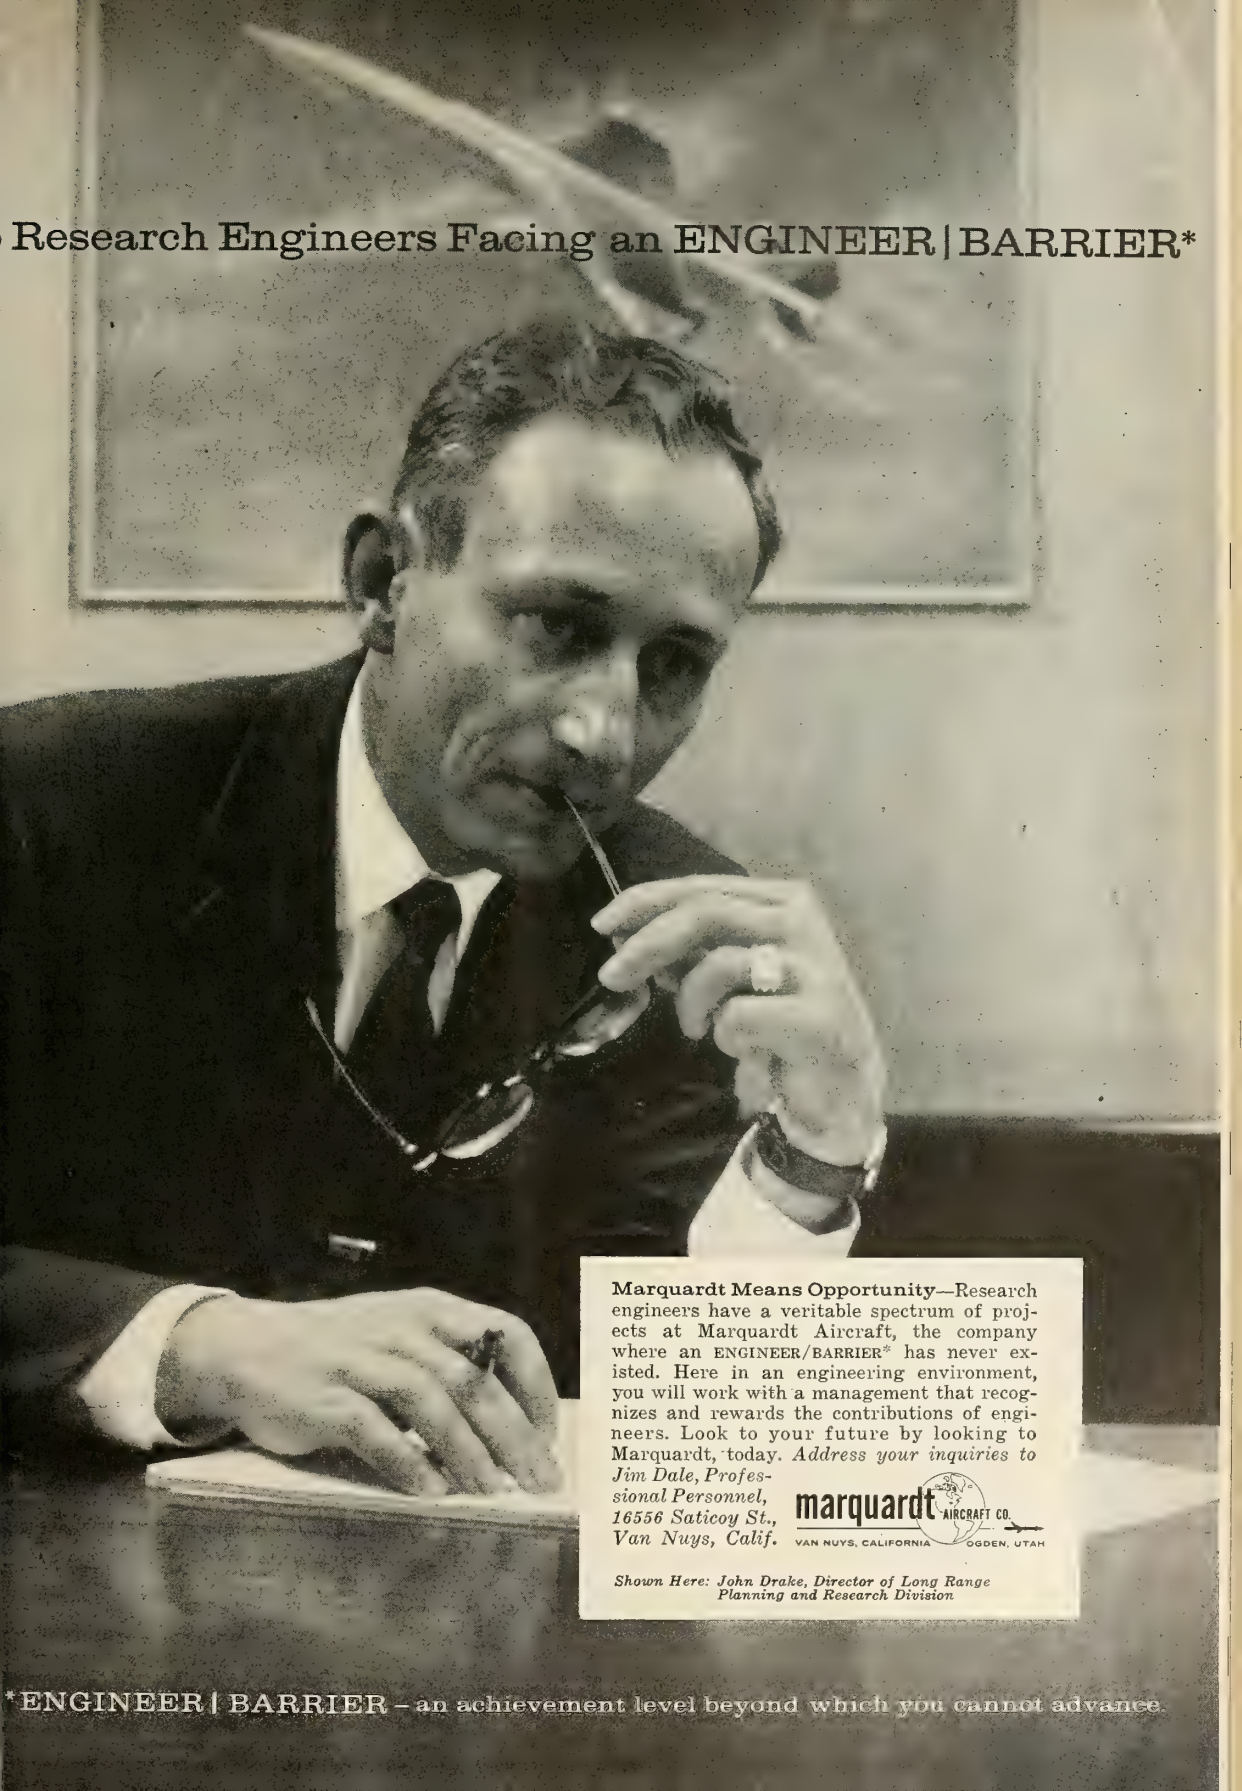
PLANNING — anticipating product trends in areas where we now operate or might enter. Actually this planning is done in a staff capacity, and normally the results end up as recommendations.

SUPPORT — to the other divisions, by introducing product improvements which offer promise for the future. These improvements generally involve a small scale program to establish the idea as feasible. This research function also may be concerned with areas which do not fit into present Marquardt projects.

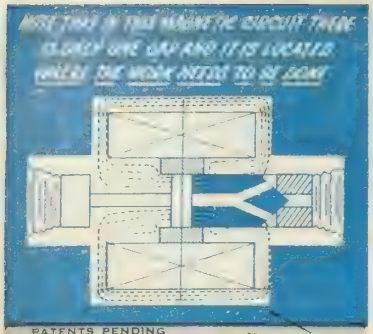
Long Range Planning and Research was begun in 1954. One of its first studies concerned areas where the ramjet can now be used or where it might be used in the foreseeable future. To date some exciting new powerplant cycles have been plotted. Some are variations of cycles now in existence, others are radically different.

Projects also have probed new "exotic" fuels, new types of diffusers, accessory systems, and controls. One phase of Aircraft Nuclear Propulsion is now being explored.

Ground was broken near Newhall, California recently for a research test center. This aerodynamic facility will have testing capabilities to Mach 14.5 as a wind tunnel and Mach 10 for free jet testing with excellent simulation of full scale flight conditions (Reynolds Number). In addition, it will permit simulation of combustion conditions to Mach 8 and altitudes above 150,000 feet.



Within this Division, research engineers will find a spectrum of research engineering opportunities, including:



DESIGN	AERO-THERMODYNAMICS
NUCLEONICS	HEAT TRANSFER
CONTROLS	COMBUSTION

For information about these positions and the professional engineering environment at Marquardt, we invite you to write Jim Dale, Professional Personnel, today.

World Astronautics

By Frederick C. Durant III

The recent "first" issue of ASTRONAUTICS was labeled Vol. II, No. 1. Don't search for Vol. I; this designation refers to the series of ASTRONAUTICS published in the thirties, before the title was watered down to: JOURNAL OF THE AMERICAN ROCKET SOCIETY.

Incidentally, the appearance of ASTRONAUTICS has caused the folding of MISSILE AWAY! and AMERICAN ROCKET SOCIETY NEWS, two splendid publications put out by the N.M.-West Texas and So. Cal. Sections of the ARS. The edict originated topside in the ARS and was aimed at maintaining control over all advertising in ARS publications. Some bitter feeling developed in the conflict over rights of sections and the national headquarters of the ARS, but apparently all has been settled amicably. These section publications were a "labor of love" representing many thousands of hours of hard work in the interest of astronautics.

Finally, there are a welter of foreign space flight periodicals issued regularly. WELTRAUMFAHRT represents the German, Austrian and Swiss astronautical societies. RUMFART is published by the Danish Interplanetary Society. The Associazione Scienze Astronautiche (Torino) publishes ASTRONAUTICA, not to be confused with ASTRONAUTICA ACTA, the official organ of the International Astronautical Federation.

The Space Flight Committee of the ARS, under the leadership of Krafft Ehricke, is making remarkable progress in hammering out recommended technical programs for the future. Eleven subcommittees have been organized under the following headings: Space Flight Operations; Spacecraft Systems; Spacecraft Propulsion Physics; Astrionics; Spacecraft Equipment and Reliability; Space Flight Mechanics; Space Physics; Legal Aspects; Sociological Aspects; Training and Education; and Documentation.

Ehricke was successful in obtaining as chairmen for these subcommittees outstanding individuals who were not already members of the Space Flight Committee. Thus, the working strength of the SF Committee has been augmented by a dozen excellent men as chairmen, plus many more individuals selected to membership of the subcommittees. In addition to the activities of these subcommittees, the Space Flight Committee itself is working on a program of action to be presented to the ARS Board. In the past the annual business meeting of the ARS has been rather dull to most casual observers. But at the annual meeting in New York this December it is predicted that some mighty interesting projects and proposals will be forthcoming.

Switzerland is known to have two well-developed guided missiles: the Oerlikon-Contraves, Type 50 Series, surface to air missile and the Oerlikon-Contraves-Boelkow *Cobra* antitank weapon. The Swiss guided missile program like the country is small. But also like the country, the program is highly developed. The development costs of these missiles have been borne essentially by private industry. Sales have been made not only to the Swiss government but to a number of other nations, as well. The USAF evaluated 25 of the early Type 50 missiles at Holloman in 1954.

The arms division of Oerlikon is justifiably famous in the arms and munitions world. During World War II the Oerlikon 20 mm. antiaircraft gun was widely manufactured in the U.S. and Great Britain as well as by the Axis countries.

How many Fenwal Controls aboard?

You might make a reservation for the first passenger trip to the moon now. But there are still some things to be determined.

We don't give you a list here of all the Fenwal temperature and control devices that may be found on board. But we do know that our past performance in solving the temperature problems on such a high proportion of modern aircraft will stand us in good stead on solving new problems. And, give manufacturers a good sense of security in adopting Fenwal devices.

For instance, in the field of fire and over-heat detection, Fenwal products are well advanced and proven in both unit and continuous types. Fenwal has the men, the equipment and the knowledge to insure fruitful exploration and practical, trustworthy products for today and tomorrow.

It will be encouraging to find, too, that your engineers will get along fine with Fenwal engineers. Our aircraft catalog on request. It's interesting. Fenwal Incorporated, Aviation Products Division, Ashland, Mass.

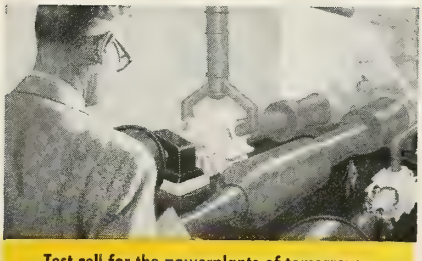
SMALL JET ENGINES...

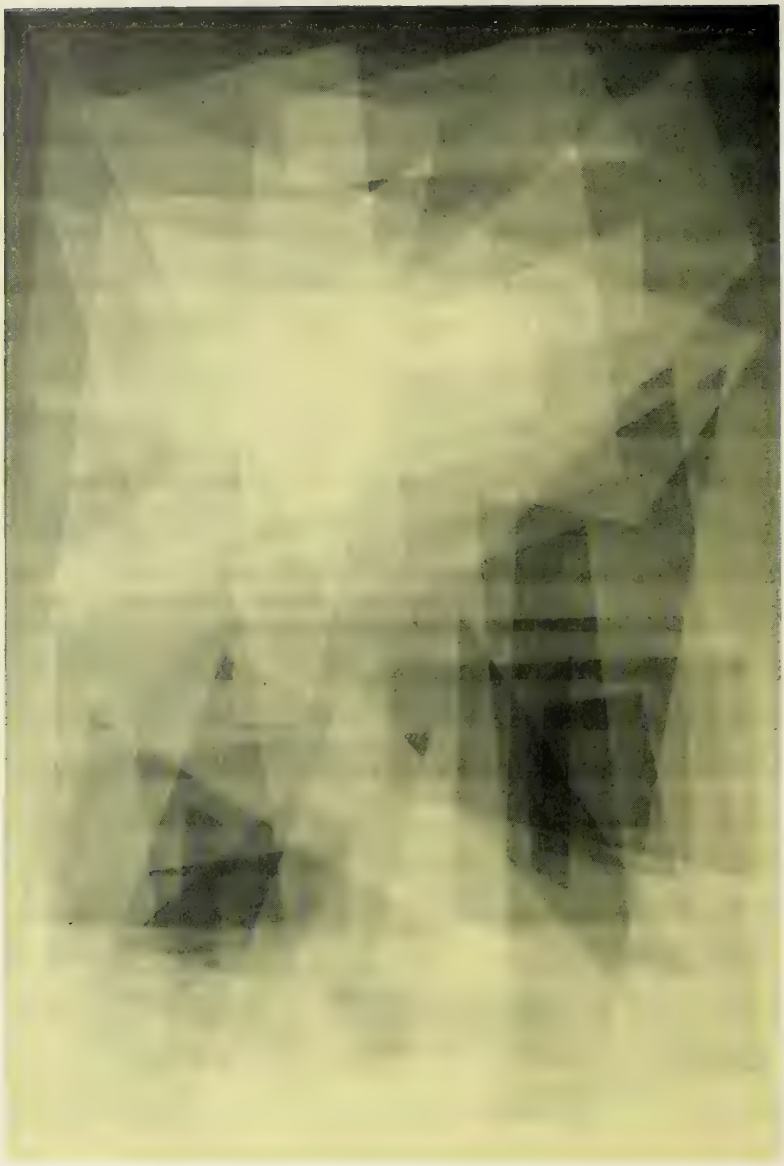


CHAMPION WEIGHT REDUCERS

The new breed of high-performance, lightweight, small jet engines coming to life will broaden the horizons of jet aircraft design, performance. versatility and utility.

Best of all, the new small jets will make possible lighter, less costly aircraft with performance to match the big planes of today. With power/weight ratios as high as 8 to 1 and long range potentials of more than 10 to 1, the small jets may power lightweight fighters, basic and advanced jet trainers, transports of half the size with proportionate savings in weight and cost. As the new airframes shrink, their performance and especially their versatility and utility expand.

Performance and potential in a smaller package . . . this is the promise held out by the new family of small jet engines of the J83 type now under development and test.



Fairchild Engine Division has long been a pioneer in aviation and a pioneer in power and is dedicated to the small jet engine concept.

Test cell for the powerplants of tomorrow—a vital link in the chain of advanced research program at Fairchild Engine Division. Equipment, experience and design ingenuity—these are the elements in Fairchild's pioneering in small jet powerplants.

WHERE THE FUTURE IS MEASURED IN LIGHT-YEARS!

"NIMBUS," a new painting by the well-known team of science-artists Simpson-Middleman. In this work, the creators have found new artistic meaning in the Moon and its reflected light. An attempt to capture the polarized nature of moonlight is made. The result, an almost half light. Collection of the Whitney Museum of American Art, New York.

Work in the world of supersonic flight—at Boeing

Supersonic flight is still in its infancy, and Boeing engineers are engaged in the adventurous task of pushing forward the frontiers of knowledge in this years-ahead world. Underway at Boeing are design projects for top-secret aircraft and missiles far more advanced than any yet developed. Related explorations delve into the required properties and capabilities of materials, fuels and systems not yet in existence. You'd find working on advanced Boeing projects a true adventure—challenging, rewarding, stature-building. Boeing offers this opportunity today to scientists, and to experienced engineers in many categories.

missiles and rockets
MAGAZINE OF WORLD ASTRONAUTICS

m/r exclusive:

Report on Missiles and Rockets Around the Globe

WHAT WE BELIEVE to be the most extensive up-to-date roundup of guided missiles and rocketry around the globe is presented in this issue of m/r. With missiles and rockets manning an ever-increasing segment of our ramparts against aggression, it is important that we note all developments in this field—wherever these developments occur.

MISSILES AND ROCKETS has closely watched the international missile industry with as sharp an eye as it watches the American missile industry. Thanks to our world-wide editorial service, it has been possible for us to keep a sensitive hand on the pulse of the rocket and missile industry around the world.

What is the international missile industry? What is it doing? Who leads in production? Who leads in research?

MISSILES AND ROCKETS has obtained the answers to these questions by sifting hundreds of reports, its editors and contributors having traveled thousands of miles, reporting in many countries. The answers are here on the following pages.

There is not one overall leader of the globe's missile industries. In Europe, Britain leads in the production of guided weapons. France has leadership in the research and development fields. On the other hand, Japan may well lay claim to leadership by her sheer enthusiasm for the future of rocketry. These are leaders. The U.S. has no claim to leadership of all missiles and rockets everywhere. We are challenged by other missile and rocket makers. They are good.

So are the Soviets. In the announcement regarding the ICBM capabilities which they claimed, the Soviet Union said:

"The solution of the problem of designing (intercontinental) ballistic rockets will make it possible to reach remote areas without resorting to a strategic air force, which at the present time is vulnerable to up-to-date means of antiaircraft defense."

Many of the Soviet missiles are as effective as Western missiles, though the high polish may not be there in all instances. As in the case of any weapon, they can kill you just as dead as a "sophisticated" model.

The Soviet arsenal is bristling with weapons that will back up the ICBM: firings of the various IRBM models take place weekly, the Red Fleet uses Arctic waters as a proving ground and test range, and a large portion of the submarine fleet is being equipped for missile handling. These submarines with IRBMs can do what the ICBM is not yet ready to do.

When the Red Army took over the German rocket centers, they sent back everything they could get their hands on. From this data and material, the Russians constructed over 1000 V-2s to acquire production techniques and for training. The Soviet version, the T-1, had an improved engine and greater range. The next step was a two stage IRBM designated the T-2, and from this evolved the T-3 ICBM, the entire program probably resembling an erector set with one assembly being "stacked" upon another.

Hence the USSR, with perhaps the largest strategic air force in the world, rendered it obsolete as soon as the Soviet Army successfully fired one ICBM. Albeit this is propaganda to enhance the effect of the ICBM announcement, it is a sign. And you don't shoot down many missiles with airplanes—just other missiles.

Britain has staked her survival on the guided missile. Sweden will make no more manned interceptors. There are greater stakes on the table—or globe—than anyone would have wagered on missiles just a few short years ago. To protect themselves against loss of this stake, the countries reported on in this exclusive roundup are encouraging rapid expansion of their respective missile industries.

The editors and contributors who have assembled the information presented in m/r's roundup include: Seabrook Hull and Norman Baker, assistant editors; Frank G. McGuire, business news; Alfred J. Zaehringer, rocket engineering; Henry P. Steier, electronics.

Also Frederick C. Durant III, astronautics; Dr. Albert Parry, Soviet affairs; Raymond L. Garthoff, special contributor, former specialist on Soviet Military Affairs for the RAND Corp.; Frederick I. Ordway, Heyward E. Canney and Ronald M. Wakeford, research editors; Franco Fiorio, special contributor on Italian affairs; Anthony Vandyk, international editor; Jean-Marie Riche, Paris; James Hay Stevens, London.

The Editors

RUSSIA . . .

Leading the World in ICBM and Satellite Development?

By Dr. Raymond L. Garthoff

FOLLOWING A PERIOD of tight wartime censorship on any disclosure of the military uses of rockets, Soviet publications in the spring of 1944 began to print articles on long-range rockets. One of the first was an article in April 1944, by the eminent scientist, military technologist and publicist, Dr. G. I. Pokrovsky, Professor Major General of the Engineering Technical Service. Its title: "The Utilization of Long-Range Rockets." This article marked the first concrete evidence of the developing Soviet interest in long-range rockets.

Lt. Gen. M. Gerasimov, an important officer in the ground forces' training program, published an article in May 1946, in the official journal, THE MILITARY HERALD, in which he raised the problem of the influence of atomic weapons and other new military technological developments on the entire military training program. He predicted specifically that: "The significance of rocket artillery, which is difficult to detect but capable of firing projectiles with sufficient accuracy to destroy targets located hundreds *and possibly thousands of kilometers away,* will grow . . ."

In January 1947, another Soviet general, Lieut. Gen. of Artillery P. N. Kuleshov, in an article in FOR DEFENSE stated that: "A great future opens for rocket artillery, *especially for long-range artillery.*" He also spoke of "rocket artillery of *strategic significance* with a range of several hundred kilometers." Finally he cited an American report on German plans for a two-stage ballistic rocket capable of attacking the continental U.S.

A third article, by Maj. Gen. of Aviation E. Tatarchenko, appeared in the official Air Force journal, HERALD OF THE AIR FLEET, in May 1946. He also called attention to the German efforts to create a rocket missile capable of bombing New York.

He stated: "Although this attempt did not meet with success, the very fact that precisely this technical task was set as completely practicable is very important." In addition, he paraphrased a statement by Gen. Arnold to the effect that: In the future it is extremely likely that rockets will be capable of hitting any point on earth, within a two-and-one-half square kilometer target area.

The Soviets use the term "long-range rockets" in describing the V-2 and other ballistic rockets of a few hundred kilometer range. In the GREAT SOVIET ENCYCLOPEDIA (late 1955), German V-2 weapons of World War II with given range of "up to 300 kilometers" are described as "long-range rockets." Consequently, general Soviet statements on long-range rockets, such as by Marshal Zhukov, must be understood as describing weapons with a range of a few hundred to several thousand miles.

The first direct communist reference to intercontinental rocket weapons systems appeared in December 1953, in an East German radio commentary by the military analyst, Egbert von Frankenberg und Proschlitz. Frankenberg stated: "Soviet long-range bombers would reach all points in the operational rear and home zones of the enemy. *The guided twin rocket (sic) suitable for transatlantic delivery has been developed further.*" A few days later (Dec. 22, 1953) the Soviet Government declared in a formal statement that "there exist rocket weapons which contemporary technology permits to be employed at ranges of thousands of kilometers, without the use of aircraft . . ."

The ambiguity was doubtless intentional. In fact, subsequent early statements were still less specific. For example, an article by an anonymous retired general, which appeared in IZVESTIA in January 1954, stated: "The contemporary development of aviation, rocket weapons, and the submarine fleet makes it possible to deal crushing blows across a distance of many thousands of kilometers."

In an article in March 1955, Maj. Gen. Pokrovsky stated that "long-range rockets capable of flying over a thou-

The latest Red statement on long-range missiles was radio Moscow's announcement of the successful test of an Intercontinental Ballistic Missile which went, in part, as follows:

In conformity with the scientific research program, successful tests of an intercontinental ballistic rocket as well as explosions of nuclear and thermonuclear weapons have taken place in the Soviet Union.

A super-long-distance intercontinental multi-stage ballistic rocket was launched a few days ago. The tests of the rocket were successful. They fully confirmed the correctness of the calculations and the selected design.

The rocket flew at a very high, unprecedented altitude. Covering a huge distance in a brief time, the rocket landed in the target area. The results obtained show that it is possible to direct rockets into any part of the world.

The solution of the problem of designing intercontinental ballistic rockets will make it possible to reach remote areas without resorting to a strategic air force, which at the present time is vulnerable to up-to-date means of anti-aircraft defense . . . the Soviet Government express gratitude to a large group of workers who have taken part in designing and manufacturing the intercontinental ballistic rockets, and the complex of facilities for their launching.

A series of explosions of nuclear and thermonuclear (hydrogen) weapons has been staged in the USSR in recent days. In order to insure the safety of the population, the explosions were set off at a high altitude. The tests were successful.

Russian Intermediate-Range Missiles and Upper-Air Vehicles

	Model	Type	Length (ft)	Dia. (in)	Range (Mi)	Status	Notes

sand kilometers exist at the present time." In a newspaper article the following month, Gen. Pokrovsky cited the statement of December 1953 as having said that "rocket weapons existed which had a range of thousands of kilometers."

The original was considerably less exact and emphatic than this.

Beginning in January 1956, a new serious line appeared in Soviet published statements. On Jan. 28, 1956, in a broadcast on the East German Radio, Frankenberg asserted that Gen. Doolittle, Senator Jackson, and the Alsop brothers were correct in their stated beliefs that the Soviet Union was ahead of the U.S. in developing intercontinental missiles.

Frankenberg declared that: "The Soviet Army, naturally, has at its disposal rocket artillery and long-range missiles." But he went further: "The overseas bases of the U.S. Strategic Air Command could not at present be protected from destruction by rockets." He did not, on this occasion, state that an intercontinental rocket existed, but by indicating that all overseas U.S. air bases were vulnerable, he implied existence of a Soviet IRBM with at least a 1500-nautical mile range.

In February 1956, at the Twentieth Congress of the Communist Party of the Soviet Union, Anastas Mikoyan spoke of Soviet ability to deliver nuclear and thermonuclear bombs "by aircraft or rocket to any spot on the globe." Marshal Zhukov, on the same occasion, spoke of Soviet possession of "powerful rocket and missile armament of various types, including long-range rockets."

These statements were reiterated by other senior Soviet military leaders, on such occasions as Armed Forces Day in February 1956 and February 1957. These statements did not specifically refer to intercontinental rockets, although the one by Mikoyan strongly indicated their existence.

The most emphatic communist statement up to that time was made in March 1956. In another broadcast Frankenberg stated that the Soviet Bloc "now possesses atomic intercontinental ballistic rockets which are capable of reaching any given point in the territory of an aggressor."

One month later Krushchev said in England: "I am quite sure that we will have a guided missile with a hydrogen bomb that can fall anywhere in the world."

Col. Metreveli admitted in MILITARY KNOWLEDGE (December 1955), that long-range ballistic missiles are "intended for firing against strategic targets disposed in the deep rear of the enemy."

Raymond L. Garthoff, for seven years the specialist on Soviet military affairs for the USAF Project RAND, and author of the authoritative book, SOVIET MILITARY DOCTRINE *(1953), presents here some previously unpublished data. He is probably the only researcher in the West to have surveyed all available military, scientific, and popular periodicals and other literature published in the Soviet Union over the past twenty years. The views expressed by the author are his own.*

Insofar as the IRBM is concerned, its potential for action against SAC overseas air bases has been emphasized. In this connection, Frankenberg's commentary of January 1956 made note of a crucial difference in an attack by the IRBM from attacks by bombers: time would not permit the enemy aircraft to evacuate these bases.

Missiles vs. Bombers

One question which arises in an evaluation of the intermediate and intercontinental ballistic rockets is their role in relation to other weapons systems with similar capabilities, particularly long-range aviation. The question was posed by Maj. Gen. Tatarchenko in the official HERALD OF THE AIR FLEET in 1946: "Can long-range rockets replace bomber aviation?" His comments, although ten years old, remain the most complete Soviet view available. It should be noted, however, that his point of departure was the British and American views on the subject, and that Tatarchenko himself, to a unique degree, sometimes expressed views at variance with the official Soviet concept. This is what he wrote:

One of the arguments for the replacement of bomber aircraft by rockets is that in the future, with perfected "thinking" antiaircraft projectiles, with the use of supersonic jet fighters with powerful artillery armament, giant bombers will simply be an unprofitable and ineffective means of long-range action.

Therefore, it seems that it would be cheaper and more reliable to send a corresponding tonnage of bombs in the form of rocket missiles. These rocket bombs, even if they did not reach their target, would despite their cost, be incomparably cheaper than hundreds of enormous aircraft, to say nothing of the absence of crews.

As is well known, in their time the Germans put into action the very same logical conclusion. Rocket bombs were produced almost exclusively, beginning in 1944, for the bombing of London and the southern part of England. They intended to attack New York, and possibly other metropolitan areas of the eastern coast of the U.S. with rocket bombs.

An underestimation of this mighty means of warfare would be a fatal mistake. To even a moderately educated person it must be clear that this new weapon in 1944-1945 appeared in an extremely primitive early form. One can hardly doubt that in the future it will develop significantly further. But does that mean that long-range bomber aircraft have passed their time, and that rocket bombs will completely replace the bomber in the air? Of course not! As the battleship did not replace the cruiser, nor the mine layer, nor the cutter, nor even the rowboat, similarly even the most grandiose development of rockets will not eliminate the necessity for any class of aircraft, least of all high-speed aircraft—bomber and transport.

High-speed giant aircraft are the foundation of strategic aviation. Missions of this form of aviation are extremely varied and cannot be accomplished with rocket bombs alone. Rocket missiles are a means of destroying stationary targets which occupy considerable area. The realm of use of rocket missiles is fairly specific. Strategic aviation resolves many times more universal missions.

While these may have been Tatarchenko's own ideas, there are indications that in general these views probably represented the attitude of the Soviet Long-Range Air Force staff at that time. Marshal of Aviation Skripko, then Deputy Commander of the Long-Range Air Force, stated in RED STAR later in 1946:

It is entirely obvious that with the contemporary level of technology the operation of formations of long-range aircraft with well-trained crews will without doubt be more effective than the dispatch of "blind missiles" alone. Strategic aviation will develop along with the appearance of new aviation weapons.

And the Soviets have acted accordingly.

More recently, in 1954 and 1955, Soviet military writers have commented on American efforts to build a strategic missile system along with the maintenance of strategic air forces. One writer, Lt. Col. Alexandrov, stated in the HERALD OF THE AIR FLEET that in the view of "some American military specialists . . . guided missiles will, in the future, replace bombers."

On the other hand, Lt. Col. Safonov, upholding the view of aircraft dominance, noted in the same journal that other foreign sources have noted that "even in 1960" ballistic missiles "will have a range not exceeding 500-600 km." and cruise-type guided missiles "not over 1000 km." range. In view of its appearance in late 1954, this gross understatement is curious and interesting. Col. Safonov then concluded with a statement which would appear to be at variance with many calculations on high-yield weapons' accuracy requirements: "An atomic missile, as a big expensive weapon, must

be delivered accurately on the target."

Maj. Gen. G. Pokrovsky said in a book in November 1956: "The German Communist military commentator, Frankenberg, whose allegations of present Soviet possession of an ICBM we have cited, nonetheless also has stated (in January 1956) that the long-range rocket weapon 'can, in certain circumstances, cause havoc, but its accuracy in hitting the target depends on many uncertain factors.' "

In the Soviet view, while the general role of bombers will continue for a long time, missiles will assume the burden of attacks on stationary strategic targets.

In the words of Maj. Gen. Pokrovsky, writing in an authoritative limited-circulation military organ in early 1955: "The destruction of targets, the coordinates of which are known in advance, will more and more be accomplished by pilotless weapons armed with atomic and thermonuclear warheads."

Again in March 1957, Gen. Pokrovsky wrote in the magazine MILITARY KNOWLEDGE of the future employment of long-range missiles against "targets previously known and precisely located on the map."

In early 1957, Engineer Lt. Col. Tiurnin, in RED STAR, noted the following advantages of missiles over bomber aviation: (1) the possibility of using mobile launchers, (2) the all-weather capability of guided missiles, (3) the opportunity for the use of missiles even under conditions of hostile general air superiority, and (4) the possibility of launching surprise blows from concealed launching points.

As one of various improvements in manned bomber systems, Red Star recognizes that: "Aviation guided missiles (air-to-surface missiles) can be employed for operations against strategically important targets having strong air defense."

One alleged Soviet source, the authenticity of which is still undetermined, is purported to be a pamphlet, presumably written by the Soviet Air Force command, published in October 1953: THOUGHTS ON AIR STRATEGY. This is said to state that the long-range bomber is obsolete, and that the ICBM is faster, simpler, less expensive and less vulnerable.

American development is said to be inferior and is criticized. In conclusion it is said, "Today's giant air bases will become bomber cemeteries in a future war." While the authenticity of this source is undetermined, the conclusions would seem consonant with Soviet thinking, with the important qualification of their reference to the future.

For the present and immediate future, it is clear that the Soviets are continuing to consider necessary the procurement of large numbers of long-range manned bombers of the *Badger, Bison,* and *Bear* types.

In the distant future another possibility is seen: nuclear propulsion of rocket missiles. As early as September 1945, Lt. Gen. of Artillery Nesterenko raised this possibility in the authoritative MILITARY THOUGHT. Again, in early 1947, Lt. Gen. of Artillery Kuleshov wrote about the possibility of using nuclear propulsion to "increase the speed, range, and power of rocket projectiles." A long silence followed during the period of intensive postwar censorship (1947-1953), but since 1954, a number of Soviet sources have written with implicit optimism of the possibility of nuclear propulsion for rockets.

One general statement, in 1954, mentioned rockets' potential for accuracy and unlimited range. Professor Kosmodemiansky wrote in a booklet: "Rocket projectiles can be shot to any distance. Contemporary successes of radar and teleguidance make possible the achievement of satisfactory accuracy in hitting the designated target."

It is from this perspective that the Soviets see the growing role of long-range ballistic missiles gradually replacing many but not all the missions of piloted bombers.

USSR Army Gets IRBM, ICBM

As we have observed, in the early postwar period several artillery generals stressed the importance of long-range missiles. In the postwar research and development program, both artillery and air force officers and institutions have played important roles. Chief Marshal of Artillery Voronov has been reported, at least as of several years ago, to have headed the whole missile program. Marshal of Artillery Yakovlev has also been active in this work.

Development of rocket propulsion units, and such work on guided pilotless bombers as has been done, have been directed by the appropriate air force agencies. Work on ballistic rockets has apparently been conducted under artillery supervision. The head of the Technical Sciences Section of the USSR Academy of Sciences is Academician A. A. Blagonravov.

Recently, several Soviet generals and marshals of artillery have been permitted to state publicly (in Col. Gen. Fomin's words in November 1956) that "long-range rocket weapons of intermediate and strategic types . . . constitute *a form of artillery*. Now artillery can be employed . . . beyond the limits of the tactical zone of operations of the ground forces."

Col. Gen. Samsonov similarly spoke of long-range rockets as "a variant of rocket-firing guns. Thus we witness a new qualitative leap in the development of *artillery*."

Marshal of Artillery Chistiakov declared that "rocket artillery can be employed for firing atomic projectiles not only in the tactical zone of operations of the ground forces and in their interests, but also *along with* (not as part of) long-range aviation for strategic purposes." No air force spokesmen have been permitted to make similar statements.

Ultimately the ICBM (and probably the IRBM) may well be absorbed in an autonomous long-range force combining this ballistic missile artillery with long-range manned (and, if employed, pilotless) bomber aviation. Meanwhile, the ground forces have operational control over all ballistic missiles up to about 1000-mile range, and probably will get some of the IRBMs.

The Soviet Navy has been permitted to develop and adapt both ballistic and guided missiles up to and probably including an IRBM for use from submarine and surface vessels, and possibly for coastal defense (which is a naval mission in the USSR). For submarine launching, emphasis to date has been on nonballistic guided missiles.

One of many statements reflecting the Soviet interest in submarine missile launching was made by Rear Adm. Pavlovich (March 1957) in SOVIET FLEET: "The possibility of using submarines for action against industrial and administrative centers of the enemy by long-range guided missiles has advanced a whole series of new requirements in combat ordnance." In addition the Soviet Navy has been developing an air-to-surface missile for use against enemy ships at sea.

IRBM, ICBM Invulnerability

General Pokrovsky in SCIENCE AND TECHNOLOGY IN CONTEMPORARY WARS, a book published in October 1956, has spelled out most explicitly the Soviet evaluation of relative invulnerability. He stated:

> In firing long-range rockets each rocket can be launched from an individual launching pad, and moreover these launching platforms can be constructed relatively quickly, quite dispersed, and well concealed. Their detection by the enemy, prior to the launching of the rocket, can be made difficult, and in any case more difficult than the detection of airfields. Therefore it will be very difficult for the enemy to prevent the launching of a rocket.

As regards interception of a missile once launched, he calls attention to the fact that:

> . . . in flight, a long-range rocket has

extremely great speed . . . One can suppose that a long-range rocket, launched by the enemy by surprise, will be detected by radar only several tens of seconds before the moment of detonation, and too little time will remain for a normal alarm and shelter of people. Thus a long-range rocket in practice achieves surprise of attack on a distant target. A massed blow of long-range rockets, launched by surprise by an aggressor against a peaceful country will be especially powerful because in peacetime the launching pads and rockets on these launchers can be prepared in concealment without possibility of reconnaissance and destruction by the defender . . .

The speed of a long-range rocket prevents its interception and destruction by conventional flying means, artillery fire, *or any other means.* It is possible that some counterweapon will be found. However, without doubt for quite awhile the probability of destruction of the rockets cannot be very great.

Defense Against U.S. Missiles

Until very recently there have been virtually no Russian reports on specific problems of defense against American ballistic and guided strategic missiles. In a rare statement (December 1956) an East German radio commentator declared that while defenses exist against guided missiles, "no defense exists against ballistic rockets. No absolutely effective weapon exists at present to counter this type of rocket weapon."

Since spring 1957 a few brief reports have been made of such defense measures through Soviet sources.

Maj. Gen. Pokrovsky, who has on other occasions been permitted to break through censorship (for example, to discuss long-range missiles, in March and April 1944), first mentioned this problem, in the March 1957 issue of MILITARY KNOWLEDGE.

In discussing American nuclear delivery systems, he stressed "the great difficulty" of intercepting long-range missiles, but without elaboration. Later in March, Lt. Col. Engineer Nikolaev wrote an article in SOVIET AVIATION, "Problems of Interception of Intercontinental Pilotless Means of Attack."

This awkward Soviet designation includes, of course, both cruise-type guided missiles and ballistic rockets. Col. Nikolaev's main theme is that basically the problem of defense and interception is the same as against bombers, and the weapons systems are thus fighters and antiaircraft artillery rockets.

On the whole, his report is important only for the fact of its existence. But one point is of interest. He declares that: "It is necessary to note that in the event of the explosion of a thermonuclear warhead even at a distance of 30 to 40 kilometers from the air defense weapons, the latter will receive significant damage and will be overcome (sic) by radioactive contamination."

It is curious that he doesn't note the similar effect of an intercepted but detonated charge on the *primary* target, but limits his comment to the effect on the air defense installation. This could mean that the Soviet air defenses are so deployed that they might be subject to damage in cases where the primary targets are not.

These comments on problems of defense against missile attack cover only some aspects of active defense. It is still true, and well appreciated by the Soviets, that (in the recent words of Rear Adm. Kruchenykh) "defense against missiles must consist in dealing pre-emptive blows on their launchers;" that is, hit them before they can be fired.

In a book published in November 1956, Maj. Gen. Pokrovsky stated:

The most effective defense against such long-range rockets is by means of their destruction in the storage places, on the paths of their transport, and on the launching platforms, where the preparation for each firing takes a rather long time. Unfortunately, one must keep in mind that the launching platforms for long-range rockets do not require very complicated preliminary equipping, and therefore, can be deployed in the most unexpected places, where helicopters can quickly bring the components of the rocket and the necessary equipment for assembly and firing. Long-range rockets can also be launched from warships, in particular from submarines.

Soviet Claims

Since early 1956, the Soviets and the East German Communists have on several occasions bragged that America lagged behind the USSR in missile development. The most extreme boasts have been made in East German commentaries. Thus, military commentator Frankenberg in January 1956, cited statements of Gen. Doolittle, Sen. Jackson, and the Alsop brothers to the effect that Soviet progress is ahead of that in the U.S. and that these were statements "whose correctness need not be doubted." In March 1956, he said that in rocket development "the USSR can never be overtaken" by the West. Another commentary was made by Kurt Shulz in December, 1956. He said:

In recent years it was believed in the U.S. that guided missiles were superior to ballistic missiles as regards range and accuracy. Accordingly, missiles controlled (guided) by various devices were created in the U.S. But all of these techniques have considerable shortcomings. They call for elaborate electronic devices built into the rocket, and for a close-knit radar network for guiding the missile. The main weakness is the high degree of vulnerability of the apparatus to electronic interference of all kinds (ECM). The Americans have only recently realized their mistake and concentrated all their efforts on the making of unguided ballistic rockets. *They are lagging ten years behind the Soviet Union, which took this path from the outset* (e.g., right after the war).

Another East German commentator, in June 1957, explained continued American interest in overseas bases, as follows:

There is, first of all, the *inadequate range and insufficient reliability* of U.S. intercontinental missiles. The intercontinental *Atlas* missile, with a range of from 6000 to 8000 kilometers, will be ready for use by the forces only in three years' time, according to U.S. reports, and it is a moot point whether these reports are based on facts. The constant chain of disaster, to which a large part of the newly developed U.S. missiles and remote control devices have recently fallen victim, will not be without effect on the further development of these weapons.

Meanwhile, since acquisition of "medium-range rocket weapons," it is said that "even greater progress has been made in developing rocket weapons in the Soviet Union. Western reports speak of two missiles with a range of 3000 to 10,000 kilometers."

Such statements as these serve a propaganda purpose and must be considered in that light. But it is true that information available, such as the account of former German scientists who worked on missile development in the Soviet Union from 1946 to 1953, do indicate an early and continuing Soviet stress on ballistic rockets, and after a few years practically none on nonballistic guided missiles.

Soviet accounts have, on a few recent occasions, also criticized alleged American inferiority in the missile field, although not with the same intensity and scope (nor disclosure of their own work) as have the East German Communist sources.

In February 1957, when Radio Moscow interviewed Academician A. A. Blagonravov (who is also a lieutenant general of artillery technical services), he stated:

The data at our disposal (not otherwise identified) show in many instances much more efficient results in this direction (experimental stratospheric rockets) than those achieved abroad—this makes our experiments more valuable than the American ones.

Similarly, late in May 1957, SOVIET AVIATION criticized the *Nike* as vulnerable to evasive action by high speed modern aircraft, and concluded that "as it now exists, the highly praised *Nike* system is far from perfect." ★

CANADA . . .

No Missiles – but Facilities and Experience

By George Shaw

OTTAWA, Que.—Canada's guided missile industry is pretty much a collection of odds and ends from the missile program in the U.S. and U.K., and though there is evidence of some original research in the field, there is no missile.

The one attempt to develop a missile in that country began in early 1951, when a group of scientists in the Canadian Armament Research and Development Establishment at Valcartier, Que., embarked on a project to create an all-Canadian air-to-air missile. Called the *Velvet Glove*, the weapon was geared specifically to the Avro CF-100 interceptor.

In all, some $24 million and about five-years' work were poured into the project before a change in government policy brought about its termination. Supporters of *Velvet Glove* insist that it was superior to the *Sparrow 2*, for which the Canadian government is currently negotiating.

Critics of the weapon maintain that *VG* was obsolescent when work first began on it in 1951, and they go so far as to say that the government lacked faith in the missile to the extent of blocking production of the almost-finished product.

Unhappily, very few of the arguments for and against the *Velvet Glove* will ever be proved or disproved, for even at this late date an unrealistic "security blanket" shrouds all but a few minor details of the weapon. And, too, many of the people involved in the project would be happy to forget *Velvet Glove* and turn to production of the *Sparrow 2*.

Production of the *Sparrow* might possibly have been started months ago but for the Canadian government's insistence that the entire missile be handed over under a single-type certificate. Many of its components are produced under separate certificates, and the process of bringing them together under one certificate has already consumed about a year.

Latest estimate is that the *Sparrow* will not go into production in Canada until at least the middle of next year.

Meanwhile, to further complicate the missile picture, Canada has acquired a new government, the first change in more than 20 years. The new defense minister has stated publicly that his department will take "a close look" at all contracts made in the recent past and affecting the present defense production picture. The contracts for *Sparrow* production have been negotiated but to date none has been signed, and one plant official said, "without a signature we can't do a thing."

The possible over-all prime contractor for *Sparrow* will be Canadair, since that company handled the *VG* contract and has gained more experience in missile hardware production than any other company in Canada. Canadian Westinghouse was prime contractor under Canadair for the electronics systems.

NIKE to defend Canadian cities.

Other companies involved in the old project were Avro, de Havilland Canada and Computing Devices of Canada. Government agencies, beside CARDE, were Defense Research Board, National Aeronautical Establishment and the RCAF. Former superintendent of the Ballistics Wing, CARDE, and leader of the original research team was Gordon D. Watson. Watson is now director of weapons research at Defense Research Board headquarters in Ottawa.

Most everyone in touch with the old *VG* project is agreed on one point: missile or no missile, the money was well spent.

Today the Defense Research Board has a core of experienced and able scientists and engineers who have had a hand in building a missile. That experience could not have been gained in any other way.

DRB and RCAF have acquired valuable know-how in testing and firing ballistic missiles and have established facilities and ranges for handling any future weapons effectively.

Canadian industrial concerns have gained firsthand knowledge of the problems and techniques of missile production. The companies involved in the *Velvet Glove* program can swing into production of a weapon such as *Sparrow* with a minimum of delay, and they all seem very anxious to "get started."

Testing centers for any future missiles will, no doubt, be the same as for *VG*. CARDE has a ground-test ballistic range at Valcartier equipped for making resonance studies, speed tests and other tests than can be made with ground facilities.

Point Petre Range, near Picton,

NIKE control plane (L) and Canadian crew (R) at joint Canadian/American exercise in the use of NIKE missile at Churchill, Manitoba.

Ont., is a short-range test-firing facility located near the Royal Canadian Artillery center at Petawawa, Ont., and close to the RCAF station at Trenton.

RCAF Station Cold Lake, Alberta, played a major role in the air firing tests of *Velvet Glove*. Station Cold Lake is the only RCAF base completely planned in the postwar period and is one of the most modern training and testing establishments in the world.

Development of the Cold Lake establishment was initiated to satisfy a critical need for a weapons range and proving ground to replace the older, inadequate ranges the services found themselves with after World War II.

Operated by RCAF Air Defense Command, Station Cold Lake is home base for the Weapons Practice Unit, Operational Training Unit and the Central Experimental and Proving Establishment. The station also operates a practice range about 30 miles north of Cold Lake which is 114 miles long and 40 miles wide.

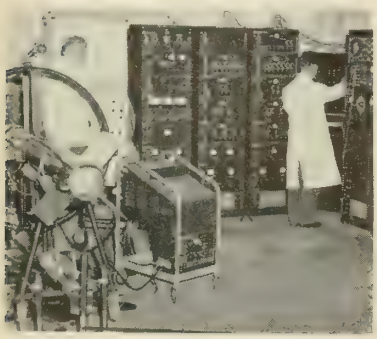
In conjunction with the Primrose Lake range, nearby Cold Lake range is used to evaluate rockets and missiles where air-to-air firing is desired and long range tracking is necessary. Telemetering and ground-controlled intercept stations are maintained at the ranges, as well as modern high-speed photographic tracking equipment.

Each of the nine CF-100 squadrons in Canada visits the Cold Lake station periodically to practice the latest methods in lead-collision course interception, rocket-firing practice and missile testing. Reliability of the CF-100's fire-control system is tested periodically on the vast ranges.

Primrose Lake, a few miles north of Cold Lake, was the primary tracking and control range used in the *Velvet Glove* project and presumably will be used in the new *Sparrow* program when it is instituted next year. Sparrows have already been tested at the Cold Lake and Primrose establishments and it is extremely likely that RCAF units are currently engaged in exercises with the missile.

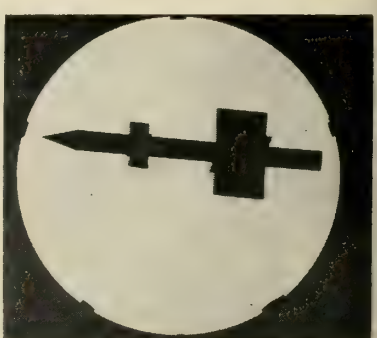
Located along the shores of Primrose Lake are nine theodolite stations used in checking velocity, trajectory paths and homing characteristics of guided missiles. The theodolites have a clear-day range of 50 miles, and are automatically synchronized for continuous tracking and computing. Digital computers are used in connection with the theodolites for rapid and automatic computation of flight data.

Summing up the missile situation in Canada is greatly simplified by the absence of a home-grown product.



Great Britain and the U.S. frequently test operational missiles jointly with the Canadian Armed Forces, and several hundred Canadians have been in U.S. Army missile centers.

Much up-to-date material on missiles and atomic research is on loan to Canada from the U.K. and U.S., and exchange agreements between the countries have kept Canadian scientists abreast of developments in the two fields.



Canada's security system is effective but cumbersome. More experience in declassification of projects such as *Velvet Glove* should eventually result in a more realistic approach to security matters in general.

Enough information on missiles is now available to Canadian scientists to warrant original research on a large scale. However, the population of Canada is about one tenth that of the United States, with a national economy to match. All-out participation in missile research would not be economically feasible.

The logical approach to the missile question seems to be the one they are taking—to use the experience gained with *Velvet Glove* to produce and weaponize finished missiles available to them from Great Britain and the U.S. ★

AUSTRALIA . . .

Proving Ground for Commonwealth Missiles

By Seabrook Hull

AUSTRALIA'S MISSILE problems are unique to the country. Its opulation—therefore, its budget—is mited. Its industrial ability cannot roperly cope with missile systems of oo complex a nature. However, hrough its Woomera test range it is aking a major contribution to West-rn missile progress.

And though its population is small less than 10 million), its land mass equiring defense approximates that f the U.S. Obviously, Australia can-ot consider its missile problems from ie point of view of playing the top ole in any future war. It must consider self as part of a coordinated alliance –as part of the British Commonwealth f Nations on the one hand, and as art of the Southeast Asian Treaty Organization on the other. Its major eed, therefore, is for tactical missiles, articularly for air defense.

In missile development, its major ontribution to date is the *Jindivik,* a igh-subsonic pilotless aircraft. Origi-ally conceived as an interceptor mis-sile, its primary mission now is as a target drone. However, studies are under way to determine its feasibility as a surface-to-surface missile of the *Matador-Regulus* type.

One of Australia's biggest missile worries at the moment is for the defense of its major cities—particularly Sidney. For this purpose it will go ahead and is already conducting studies of missiles like *Talos, Nike* and the United Kingdom's *Bloodhound.* No decision has been reached as to which one is favored. But cost and availability, as well as operational ability, are factors. Target for the study is to start installing missiles around Australian cities sometime in 1959.

Royal Australian Air Force prefers the de Havilland *Firestreak* for air-to-air work. This heat seeker may be completely manufactured in Australia. Certain components are already locally made.

The Australian Government does not yet know whether it will buy these missiles outright from abroad or whether they will request licensing authority and manufacture them in Australia. "It all depends on their complexity and demand on natural resources."

Meanwhile, Australia's missile program has not been without its advantages. It recently sold ten *Jindivik* "pilotless aircraft" to Sweden for £500,000 ($1,115,000). Price included ground control equipment and spare parts. The *Jindivik* can top 50,000 feet.

Meanwhile, if any nation has room to spare for an overland missile test site, it's Australia. Thus, the Woomera Range in central Australia is of vital importance not only to Australia's but Britain's missile development. Sooner or later, virtually all of Britain's missiles are tested at Woomera. Also, the Woomera base is being used during the International Geophysical Year for satellite tracking and for launching upper-air research rockets such as Britain's *Rockoon*-like system, the *Bobbin.* ★

Missiles don't do much good in this kind of fighting. Australia's missile arsenal is being tailored to her peculiar needs.

Australia's greatest contribution to the free world's missile effort is the massive overland test range at Woomera where these shots were taken. Upper left is the BOBBIN ramjet test vehicle produced by Bristol Aeroplane Co. It is parachute-recovered. Lower left shows a SKYLARK in its launching tower for firing. Below is the pilotless target plane JINDIVIK. Above is a dramatic view of Britain's FIRESTREAK infrared guided missile just after firing. Virtually all British missiles are tested at Woomera.

GREAT BRITAIN . . .

Takes Lead in NATO Missile Production

By James H. Stevens and Ronald C. Wakeford

BRITAIN'S MISSILE POLICY was announced by Defense Minister Duncan Sandys last April. It was simply that in order to economize defense measures and so reduce the annual budget, the UK would:

1) make the English Electric P-1 (and stretched versions of it) the last manned fighter airplane;

2) make the Avro Vulcan B2 and the Handley Page Victor B2 the last manned bombers;

3) make all interception by missile after interim introduction of a single operational AAM, the DH Firestreak (for Royal Navy as well as RAF use);

4) increase range of second-generation V-bombers by Avro stand-off bomb, pending ICBM;

5) abandon area protection of the British Isles, including population centers and even defense plants, in the face of nuclear warhead missile attack;

6) restrict target defense to the bomber (later ICBM) retaliation bases.

Until very recently there was a widespread feeling that the British missile industry was a damp squib. But for many years now the rumblings at Aberporth, South Wales, and Woomera, Central Australia, have indicated that some form of missile research was taking place, but little was said for publication. But recently, photographic and data releases by the Ministry of Supply have shown that the UK is much further advanced than was generally realized.

A few months ago information presented to Parliament by the Minister of Supply named two missiles (*Firestreak* and *Bloodhound)* and another vehicle (unnamed) to be manufactured by the English Electric Co. Details of the *Sea Slug* were made available more recently.

The Society of British Aircraft Constructors (SBAC) has announced that 400 British companies are engaged in missile development and supporting work.

Most notable of the companies manufacturing missiles are: Bristol Aircraft Ltd., English Electric Co., DeHavilland Propeller Ltd., A. V. Roe, Fairey Aviation and Vickers-Armstrongs. Bristol Aircraft has four plants concentrating their efforts on missile work. Ferranti, manufacturers of guidance equipment, which is associating with Bristol on one of its projects, has two plants giving support to the missile program.

Others include: E. K. Cole & Co. Ltd. *(Fireflash* radar), E.M.I. Engineering Development Ltd., The General Electric Co. Ltd., Sir George Godfrey and Partners, Imperial Chemical Industries, McMichael Radio Ltd., Metropolitan Vickers Ltd., The Sperry Gyroscope Co. Ltd., The John Thompson Conveyor Co. Ltd., Vickers-Armstrongs Ltd.—all *Sea Slug* ancillaries.

Rolls-Royce Ltd. (Rocketdyne License), Avica Equipment Ltd., The British Thompson Houston Co. Ltd.,

A development model of Britain's SEA SLUG fires from the forward triple launcher of the HMS Girdle Ness. Note four typically British wrap-around boosters clamped to missile body.

S. G. Brown Ltd., Burnley Aircraft Products Ltd., Delaney Gallay Ltd., Diamond H. Switches Ltd., Dowe Instruments Ltd., Elliott Brothers (London) Ltd., Goodmans Industries Ltd., Graseby Instruments Ltd., High Pressure Components Ltd., Hymatic Engineering Co. Ltd., I. V. Pressure Controllers Ltd., Kelvin and Hughes Ltd., King Aircraft Corp. Ltd., Laporte Chemicals Ltd., Lion Electronic Developments Ltd., Muirhead and Co. Ltd., W Bryan Savage Ltd., Smiths Aircraft Instruments Ltd., Solartron Electronic Group Ltd., Teddington Aircraft Controls Ltd., Vactric (Control Equipment) Ltd., Venner Ltd., W. Vinter Ltd., Western Manufacturing (Reading) Ltd.

Missile Budget Secret

The actual money spent on the missile program has never been revealed, but is "for security reasons" lumped in with the general aviation vote.

The full scope of the operational weapons program has not been revealed, although rumor has it that Vickers-Armstrongs has not only had its *Red Dean* AAM cancelled, but that the company's ICBM—also well ahead—was cancelled.

Missile bases for testing or indoctrination of personnel are either established or are undergoing construction in several areas. Two of the newer facilities are the RAF missile station being completed at North Coates, Lincolnshire, and the joint services test range, South Uist, Outer Hebrides. The former will see service missile trials in 1958. Some missile development testing has been undertaken at the Royal Artillery range at Larkhill.

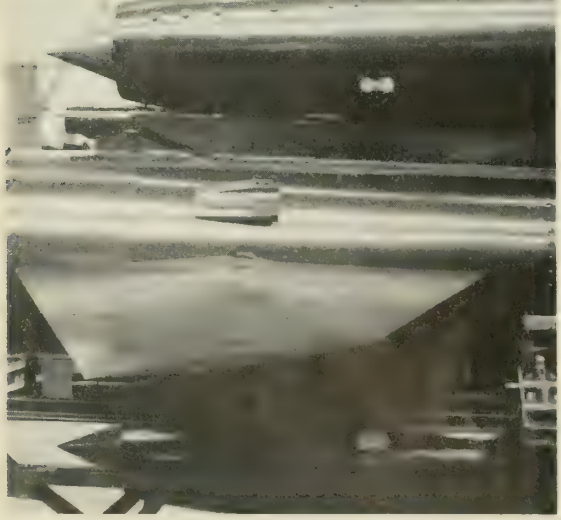
Just how far Britain has advanced in the missile field, and what its position is in relationship to the U.S effort, has yet to be established. More information will have to be released before a true picture can be drawn.

British separation and boosts, based on the wrap-around principle, aim at maintaining a minimum vehicle length to facilitate launching, handling and transportation. Wrap-around boosting also keeps C. G. shift at separation to a minimum and requires no additional stabilizing fins. Separation by aerodynamic means is somewhat simpler with tandem boost. Air pressure lifts away the booster units to a predetermined angle before separation is achieved.

The Fairey Aviation Co. was probably the first to make a production missile. Background to this work was the *Stooge*.

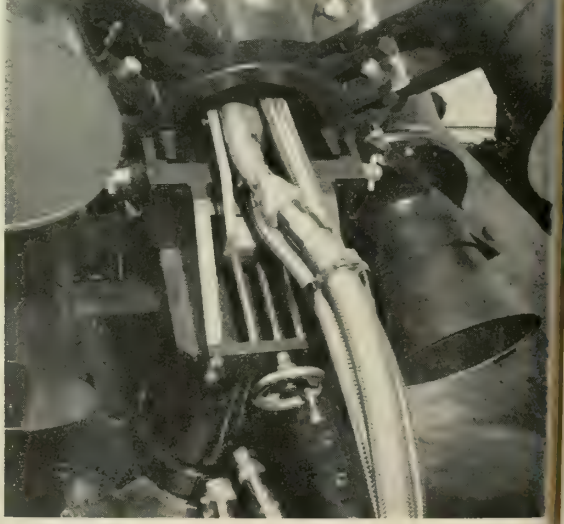
FIREFLASH

The history of the Fairey *Fireflash*, which was Britain's first operational entry in the air-to-air missile field, dates back to World War II. At this period the Royal Air Force's need for this type of weapon was fully understood and a series of developmental programs was initiated. During 1953, an early version of the vehicle successfully destroyed a *Firefly* drone.



The *Fireflash* is somewhat unique, in that it has no sustainer motor. The solid-propellant boosters of the wrap-around type accelerate the vehicle to maximum velocity and then separate, allowing the missile to coast to the target.

The two boosters jut out well ahead of the proximity-fuzed warhead. The main body is tubular with cruciform wings and guide vanes. This makes a fairly bulky, high-drag missile suited to under-wing carriage, but scarcely to stowage in an internal weapon bay. It uses a Marconi beam-rider guidance system. The missile is homed by the launching airplane and is entirely dependent upon the lock-on capabilities of this aircraft's radar. The equipment includes countermeasures against enemy jamming. *Fireflash* is used on the Supermarine *Swift MK7*, the Hawker *Hunter*, and Australian-built *Avon-Sabre*. It is now a training weapon for Fighter Command.

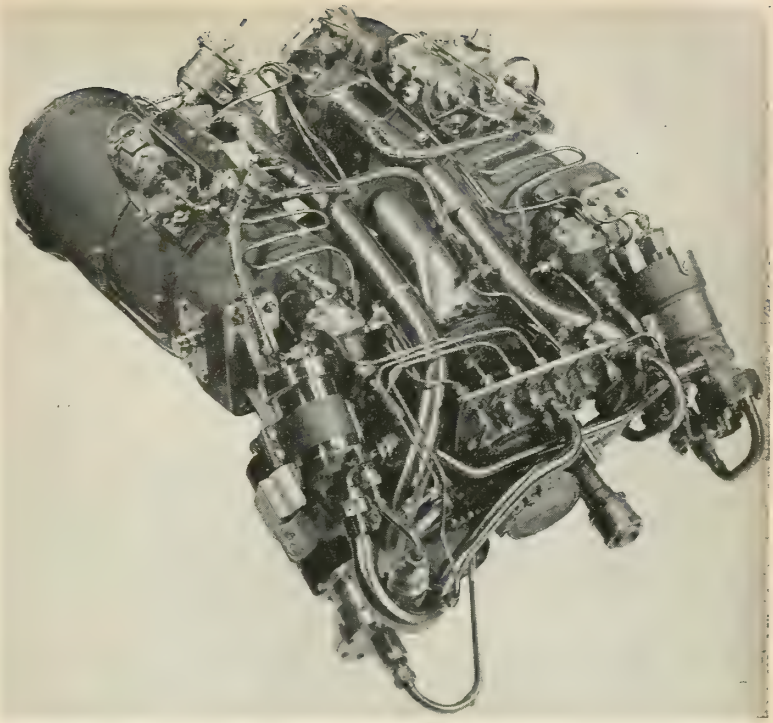


FIRESTREAK

Another air-to-air missile about which the Ministry of Supply has released information is the *Firestreak*. This missile is produced by DeHavilland Propeller Ltd. Passive homing is achieved by means of an infrared seeker. Geometrically the missile is of conventional form with cruciform-shaped wings and fins. It is slated for delivery to the RAF around the end of 1958. The vehicle is now propelled by a single solid-propellant motor.

It is a rather larger missile than the *Fireflash* because its accelerating rocket motor is mounted inside the body of the weapon itself. It is claimed that apart from the electrical and pneumatic activating and launching circuits, an infrared sensing GW requires no special equipment on the aircraft.

A close-up view of the double-wedge five per cent airfoil hinged wing attachment, booster slipper bracket and front of THOR ramjet.



This aft view of BLOODHOUND shows hinged assembly ring for wrap-around boosters as well as hydraulic and pneumatic fittings

As an aircraft, *Firestreak* is a simple supersonic cylinder with cruciform wedge-section wings and tail blades in the same plane. The rearward positioning of the wing is a common supersonic stability feature. Longitudinal strakes appear to be fairings for wing attachments and control leads. Because of the optical nature of infrared wavelengths, the conical nosecap is octagonal in order to provide nondistorting glass "viewing" panels.

Infrared radiation cannot penetrate thick cloud—so prevalent in Northern Europe—but the RAF Air Staff evidently considers that attackers from the East will come in at 50,000 feet, and thick clouds are unknown in the stratosphere.

Two of Britain's RAF fighters, the English Electric P-1 and the all-weather fighter Gloster *Javelin* are scheduled for mating with the *Firestreak*. Royal Navy will also use it on its DH *Sea Vixens*. Range is about eight miles and length approximately seven feet. The *Firestreak* can be teamed with any fighter, the makers claim.

The first production version of the *Firestreak* will shortly be available for export to friendly nations.

Detailed picture of Napier Double SCORPION NSc. D.I. used to attain the altitude in a Rolls Royce Avon-powered CANBERRA. It is a double-barreled version of the NSc. I rocket.

Red Dean

The *Red Dean*, another addition to Britain's air-to-air armament, is believed to have been cancelled. Little information has been released. Vickers-Armstrongs is the contractor. If, as has been reported, this missile has been abandoned, it is probably due to the cancellation of the Gloster *Javelin*. *Red Dean* was tailored to team with this airplane.

Ground-to-Air

Research vehicles bearing such names as RTV 1 & 2, GPV and MTV sparked Britain's surface-to-air missile program and led to such vehicles as *Bloodhound*, *Thunderbird*, and *Sea Slug*. These missiles are now in production.

Bloodhound

The Bristol Aeroplane Co.'s contribution to the nation's defense against air attack is the *Bloodhound* missile. Ferranti Ltd. manufactures the semi-active guidance system. This missile has been under development since 1949.

Sustaining power is supplied by two Bristol *Thor* ramjet engines of "virtually 100% starting reliability," the Bloodhound being boosted to operating velocity on the order of 1500 feet per second by solid-propellant boosters. Hundreds of rounds have been fired from Aberporth and Woomera. This testing will continue at the new range being constructed at South Uist in the Hebrides.

It is a neat little supersonic airplane: cylindrical blunt-tailed body with ogival nose, tapered stub wings with cut-back tips set well aft, rectangular fixed tail plane and one *Thor* above, the other below the fuselage on short pylons. Unlike the symmetrical cruciform rocket missiles and coaster, which are steered by pitch and yaw without banking, the *Bloodhound* is rolled into a bank and turned by elevator action. The reason for this is that the jets from the two *Thors* make it impossible to mount vertical tail surfaces, while the ramjets themselves prevent the fitting of cruciform wings.

The *Bloodhound* wings have no ailerons because all-moving surfaces are best at supersonic speeds. Roll is by differential displacement of the wings, with pitch control by alteration of wing incidence in unison. Concentration of the jacks and operating equipment at the middle of the aircraft is a highly desirable feature, both mechanically and for weight-control reasons.

Construction is simple, expendable stuff—light-alloy fuselage with fabricated light-alloy wings and tail, which have plywood-filled tips. The wing airfoil is a double-wedge, five per cent thick, unswept and hinged on a tubular spar at the mid-chord point. The tail plane consists of two rectangular units bolted to a mounting ring let into the tail of the fuselage, with a one-inch thick airfoil of flat-plate form with leading and trailing-edge entry wedges.

Bristol Aero-Engines's *Thor* ramjets are fabricated from 18/8 commercial stainless steel, mainly by welding. The powerplant is of elemental supersonic form—just a plain tube with centerbody double-shock air intake and convergent-divergent nozzle. All intakes visible in photographs are either dummies or have been retouched so as to conceal the missile's capabilities. The venturi nozzle is formed by a curved internal plate spot-welded to the skin, which is cooled by a row of joggled holes in the outer surface. On a diameter of 15.75 inches and length of 100 inches, the *Thor*, it has been unofficially stated, is capable of delivering 15,000 pounds thrust at M 2.0 at sea level. It has been tested on the *Bobbin*.

At the front of the mounting pylon of each ramjet is a cylindrical air intake for ram-air, fuel and hydraulic turbopumps.

The *Bloodhound* launcher is a robustly-built unit with a hydraulically powered turntable and elevating ram. The launch angle is constant at 45° and the ramp is locked at this angle by hand-pins in the support-truss hinges. Supplies fed thru the ramp to the missile are high- and low-oil pres-

sures, compressed air and multiple electronics—nearly 100 circuits.

Each of the *Bloodhound's* four boost rockets has a thrust ring (mounting the tail stabilizing fin) hinged to a central mounting ring that fits over the missile's tail. At the front of each rocket case is a ring with a W-shaped bracket that has two fore-and-aft lugs sliding into a slipper casting on the missile. At burnout, the boost assembly slides aft a few inches, the front attachments disengage and the cases umbrella outward, so that the whole assembly falls off backward as a cruciform unit.

The *Bloodhound* will be Britain's first production ground-to-air vehicle. The vehicle is backed up by an excellent radar control system, which integrates acquisition radar, lock-on and tracking radar and the launching site equipment into an automatic launching and firing system. This same system is adaptable to the characteristics of other surface-to-air vehicles in production.

THUNDERBIRD

The second most publicized of Britain's surface-to-air weapons is the *Thunderbird*. This vehicle is a product of the English Electric Co. and is believed to be moving rapidly from development status to full production.

Thunderbird is a beam rider, the guidance system being manufactured by Marconi Co. Ltd., and the liquid-propellant powerplant by D. Napier & Son Ltd. Four wrap-around, finned, solid-propellant booster motors provide launching thrust.

It is a straightforward rocket-propelled missile of "classic" supersonic form. It has a conical-nosed cylindrical body, with symmetrical low-aspect ratio tapered wings set well aft and tapered tail-control blades. Some versions were powered by Napier NRE 17 RTP/kerosene liquid rockets, giving over a ton of thrust, but for ease of operation in the field, RAE solid propellants have now been substituted.

As of this writing, practically no information has been given on *Thunderbird*, but it appears to have semi-active homing guidance, designed, developed, and manufactured by Marconi's Wireless Telegraph Co. The essential difference from the *Bloodhound* is that the *Thunderbird* has its own individual and independent radar so that it can be sited anywhere.

The *Thunderbird's* configuration is similar to English Electric's test vehicles. This would indicate that the overall length is about 20 feet and the diameter, 15 inches.

Built to similar specifications, the *Thunderbird's* performance is expected to be generally of the same order as the *Nike-Hercules*. A self-contained mechanical system for ground support of the missile has been developed in common with American counterparts.

SEA SLUG

The Royal Navy's only entry in the missile field, at least as far as official releases are concerned, is the *Sea Slug*. Many companies had a hand in the construction of this vehicle, the most notable being Armstrong Whitworth (prime contractor), General Electric Co. (guidance), and Sperry Gyroscope Ltd. (control system).

The Admiralty makes the point officially that this is a Navy-designed WS and that the contractors are essentially only suppliers—Armstrong Whitworth having full design responsibility, however, for the aerodynamics.

Sea Slug has movable fins with large rectangular wings and is said to be of medium range capable of reaching any altitude at which an enemy fighter intrudes. Wrap-around solid-fuel boosters are provided which separate as the vehicle becomes supersonic.

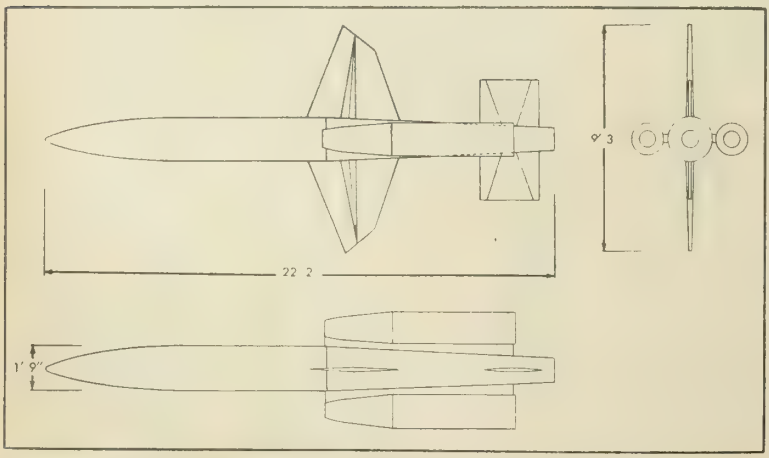
Although it was first thought that an Armstrong Siddeley liquid rocket-propellant motor would power the final version, the trend to solid-propellant sustainer motors is also overtaking the *Sea Slug*.

Designed as a fleet defensive weapon, the missile began its sea trails a little over a year ago aboard the *HMS Girdle Ness*, a naval guided weapons ship. *Sea Slugs* are fed to the triple launchers on deck automatically and fired remotely.

Shore-based testing of the vehicles was programmed on the Clausen Rolling Platform, a small ship in itself capable of a 10-degree pitch and 20-degree roll.

Air-to-Surface

The British industry has yet to name its first guided missile of the air-to-surface category, but it is known that A. V. Roe is well on its way to producing the first model. This class of vehicle is commonly referred to in British journals as the "stand off bomb."



The vehicle is designed to be carried by the RAF's "V" bombers *(Vulcan and Victor)*, and it is believed that the missile will be approximately the same size as the *Rascal*.

Surface-to-Surface

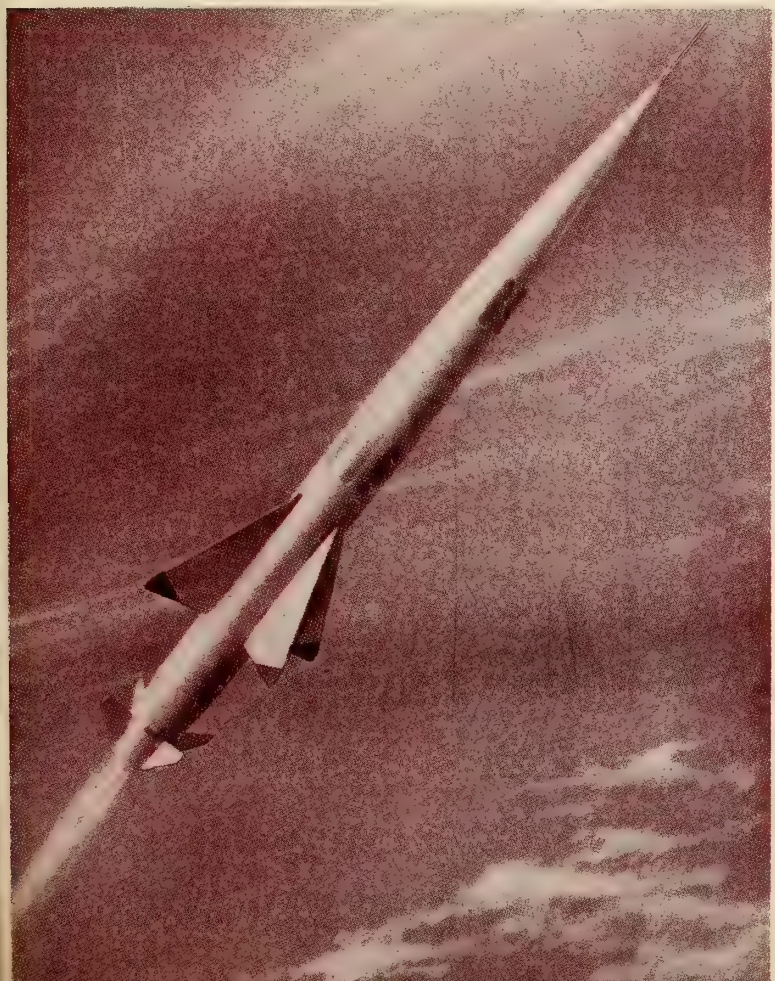
Britain probably obtained its start in the surface-to-surface missile business with a 1916-vintage guided airplane. This vehicle, known as the *Aerial Target*, was a radio-controlled monoplane developed at the Royal Aircraft Factory. More in direct line with recent developments were the British firings of V-2's from Cuxhaven, North Germany, just after the war. At this point all references to activity in this field ceased until very recently.

Today the only development along this line is apparently being undertaken by the DeHavilland Co. which is developing a 2000-mile IRBM in conjunction with Rolls Royce for the RAF. Reports suggest that these two companies have been working on the vehicle for five years or more. The vehicle may be powered by a North American rocket engine made by Rolls Royce.

The Ministry of Supply's Ballistic Missile Division is coordinating the surface-to-surface work through the Royal Aircraft Establishment, Farnborough. The IRBM will carry a nuclear warhead. Meanwhile, the U.S. *Honest John* is used for training; the *Corporal*, for bombardment. An anti-tank weapon is being developed by Fairey Aviation in the smaller category of surface-to-surface vehicles. This missile will probably be used for air-to-ground applications also. ★

Plan views of Britain's main ground-to-air missile effort, the Bristol-Ferranti BLOODHOUND.

SWITZERLAND . . .



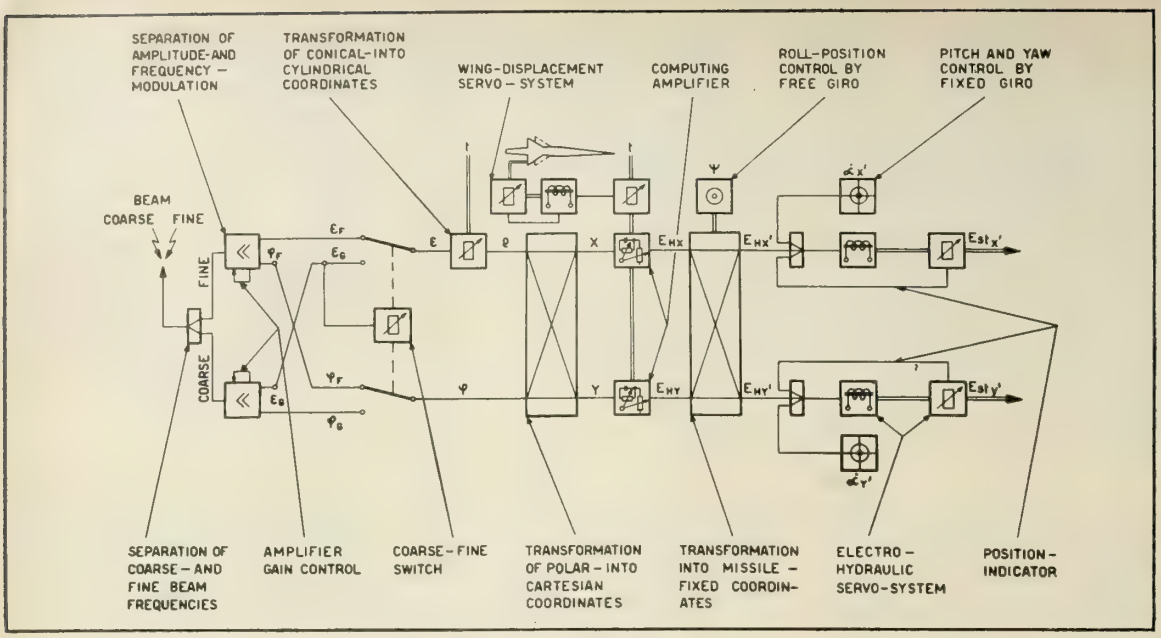
Missile Design with Watchmaker Precision

By Frederick C. Durant III

THE SWISS MISSILE industry and Oerlikon are virtually synonomous. The reputation and achievements of Oerlikon have been carried over from the field of conventional weapons to guided missiles, currently produced by the firm for use by Switzerland and various foreign countries. Of the company's production missiles, two stand out—the Type 50 series SAM and the *Cobra* series antitank rocket.

Development of this antiaircraft weapon commenced shortly after the past war. The Type 54 is a slim, streamlined, rocket-propelled weapon, capable of interdicting aircraft at altitudes up to about 50,000 ft. It is single staged, fired from a dual-position zero-length launcher. Overall dimensions are about 20 ft. long and 16 in. in diameter; launching weight is 770 lbs. The missile has two sets of cruciform wings. The main (forward) wings, which provide lift necessary for controlled flight, move forward to adjust for center of gravity shift during powered flight. The after wings are used for gas-jet steering after burnout.

Oerlikon's Type 54 antiaircraft guided missile.



The propulsion unit is a liquid propellant, nitric acid-JP type system which produces a thrust of about 2200 lbs. for 30 seconds. Propellant supply: compressed nitrogen gas at 300 atm. pressure, initially. Specific propellant of the engine is about 12 lb./ton/sec. A starting fuel of triethylamine and xylidine is used to obtain smooth ignition. No booster unit is employed. Burnout altitude is about 30,000 ft.

Fuselage construction is of wound aluminum alloy utilizing metal-bonding adhesive. The wings are of sandwich construction.

Guidance of the Type 54 is a beam-rider system. Ground units operate a radar target tracker and guidance beam path simultaneously. The missile is launched into the guidance beam and rides the center of this beam. The target-tracking radar feeds information on azimuth and elevation angles through a ground computer (to correct for parallax) to the missile guidance beam which guides the missile to target. A proximity fuze fires the warhead if actual impact is not obtained.

This weapon system is complete and has been available for purchase for nearly three years. In addition to Switzerland, Sweden and Italy are also employing this weapon. Japan has recently acquired a license to manufacture. The Type 56 model is an improved version and a newer, Type 57 version is known to be under development.

The *Cobra* is a wire-controlled, solid-propellant rocket antitank weapon.

Above is a schematic diagram of the Oerlikon rocket control system showing the main components and their relationship to one another.

Closely resembling the French *SS.10* and *ENTAC* in size and design, the *Cobra* is manufactured by Oerlikon-Contraves-Boelkow. All these weapons are a follow-on of the German World War II development, the *X-4*. Weighing about 24 lbs., maximum range is slightly less than one mile. Maximum velocity is about 190 mph. Like the similar (but shorter-ranged) shoulder-fired Bazooka rocket, an armor-piercing shaped-charge warhead is utilized. The *Cobra* weighs only about one-tenth of the U.S. Army *Dart*, a similar wire-controlled weapon.

Although unguided, mention should be made of the outstanding 5-cm. and 8-cm. FF,FF (forward firing, folding fin) rockets. These highly effective air-to-ground rockets have been developed for the Gloster *Meteor* and *Venom* aircraft. Launching is from streamlined pods. The *Meteor* carries 76 5-cm. rockets which are fired in pairs at intervals of 0.1 sec., the complete salvo occurring in about 3.5 sec. The *Venom* carries two launchers slung beneath the wings, each carrying seven 8-cm. rockets and firing in pairs. Impact-fuzed, shaped-charge warheads are utilized. A proximity fuze is under active development. Electric power to operate a miniature radar unit is obtained from a gas turbine generator driven by gas "bled" from the rocket combustion chamber in flight. The warhead is fired at the moment the reflected radar signal from the target begins to diminish in strength. ★

Two versions of the Oerlikon antiaircraft guided missile shown being launched. The missile is steered by a combined gas-jet rudder. Four cruciform delta-wings produce the lift force necessary for curved flight, while the four rear fins act as steering controls.

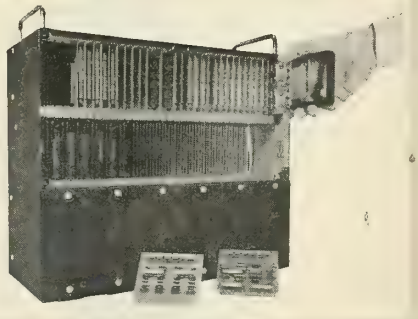
Production of communications equipment in new Los Angeles manufacturing plant



Data Reduction Center designed and built by Ramo-Wooldridge

One of three new research and development buildings completed this year

First unit of Denver manufacturing plant now nearing completion

Input-output unit of the Ramo-Wooldridge RW-30 airborne digital computer

Pictorial **PROGRESS REPORT**

The photographs above illustrate some of the recent developments at Ramo-Wooldridge, both in facilities and in products. Work is in progress on a wide variety of projects, and positions are available for scientists and engineers in the following fields of current activity:

- Communications and Navigation Systems
- Digital Computers and Control Systems
- Airborne Electronic and Control Systems
- Electronic Instrumentation and Test Equipment
- Guided Missile Research and Development
- Automation and Data Processing
- Basic Electronic and Aeronautical Research

SPLIT-SECOND MISSILE CONTROL AT 15,000 MILES PER HOUR

BURROUGHS GROUND AND AIRBORNE COMPUTATION "THINKS" FAR AHEAD OF SUPERSONIC MISSILES

Eye-defying speeds characterize today's ballistic missiles, and their effectiveness depends on accurate guidance.

That means electronic computation—and *telemetering*, which now keeps ground guidance control instantaneously informed of what's going on within and around the missile in flight: directional variances, atmospheric density, propulsion performance and so on.

Electronic computation, telemetering, high-speed read-out devices for airborne control or ground missile guidance . . . all are identified with Burroughs in today's vital defense contracts. From initial research to actual installation and field services Burroughs participation extends to instrumentation, control systems, communications and other facets of electronic computation.

We welcome inquiries regarding projects in any and all areas of our proved competence. Write, call or wire Burroughs Corporation, Defense Contracts Organization, Detroit 32, Michigan. Or Burroughs Defense District Offices: Paoli, Pa. • Dayton, Ohio, 3898 Linden Ave. • Encino, Calif., 17071 Ventura Blvd. • Washington, D.C., 1145 Nineteenth Street N.W.

FRANCE . . .

Advancing Missile Science Through Uninhibited Thinking

By Frederick I. Ordway, III

FRANCE has accomplished much, with relatively limited resources, in the missile field. She has realized that success can come only by following certain limited avenues of research and development, and it is obvious to her that it is impossible to attempt to create broad categories of highly costly and complex long-range missiles such as found in the U.S. and USSR.

Like its airplanes, French missiles are specialized, and result from a careful assessment of the kind of war in which the nation might become involved. Keeping this specialization in mind, and looking forward to closer R&D cooperation between European NATO powers, it is probable that French missilry will become an increasingly important factor in European defense in the years to come.

Since the war France has moved into the forefront of world rocketry. They enlisted the aid of a number of German scientists, including Sänger, Sänger-Bredt and Zborowski, but otherwise have developed along independent lines.

Promoters of French rocketry have long been pressed for funds, and have had to work with only limited resources. Money is still short, but recent increases accorded both R&D and production have helped considerably. With what it has available, France has adapted and improved several German concepts and has advanced many new, original and brilliant solutions to their own problems. The crucial electronic industry has enjoyed a particularly spectacular advance in France, which has aided missile development.

With an eye on both economy and the European tactical and strategic picture, France has restricted her rocket programs to those she feels essential and within her means. Light industry has adapted well to the age of missiles. Heavy industry, on the other hand, experienced some difficulties in obtaining qualified personnel, particularly on the worker level. The situation there, however, has improved.

Industry and defense agencies have discovered that closer-than-normal cooperation has become necessary to properly develop the missile field. This has created consequent modifications in habitual French independence, causing some departure from traditional ways of business.

For both the military and the entrepreneur, the missile age has brought important changes in France, both organizationally and mentally. That the country is adapting well, however, seems evident.

Proximity-fuzed PARCA SAM leaves launcher.

Background to Developments

It is hard to tell just when French rocketry began. Before the first World War, Rene Lorin wrote of a reaction propelled rocket plane in the AEROPHILE, a concept later enlarged into book form, and in 1911 Dr. Andre Bing received an important rocket patent. During the war no other country save France employed rockets operationally. Both surface-to-air incendiary rockets and air-to-air *Le Prieur** types flown on *Nieuports* were used against German Zeppelins and captive balloons. There is also 1915's catapult-launched *Torpille aerienne,* which was a primitive, radio-gyro controlled flying bomb, a World War I V-1. This 1100-pound SSM could carry a 440-pound payload. The French also used 27 and 34 mm signal rockets from 1914 on.

In 1912 Robert Esnault-Pelterie spoke before the French Physical Society on rocketry and in 1927 gave his famed lecture to the French Astronomical Society on the subject "Exploration of the Very High Atmospheric Regions by Rockets and the Possibility of Interplanetary Travel." This was later enlarged and published as a book.

** Invented by Navy Lieutenant Vaisseau Y. le Prieur, Nieuport Scouts carried four rockets on each side. In one engagement in the spring of 1916 four enemy balloons were set afire by these early AAMs. See* LA CONQUETE DE L'ESPACE, *V. Coissac, Tours, 1916.*

French rocket-astronautical promoter-author Ananoff (right) at first IAF Congress.

During the 1930s Damblanc and others made important contributions to rocket literature. Damblanc, incidentally, was first to photograph multistage rocket separation. Esnault-Pelterie worked with the Armament Fabrication Technical Services at St. Cloud and, having developed a light alloy motor, made many experiments with gasoline-ether and liquid oxygen propellant combinations, starting in 1934. Firing took place at the French Army Proving Ground.

In 1937 an astronautical-rocket exposition took place at Paris' Palais de la Decouverte. Rocket-propelled bombs were studied by Rougeron and J. J. Barre who, with the aid of Arnould, Genty and Dubouloz, conducted a static test on the EA-41 rocket during 1941 under the noses of the Germans. I.M. Tercet tested small powder rockets. The EA-41 was unguided, fin-stabilized, and ten feet long. Immediately following V-E day, a 35-mile flight was made near Toulon in Southern France, at a maximum thrust of 2200 pounds for some 13 seconds firing time.

Rocket-Astronautical Activities

While rocket developments in Germany and America followed the growth of rocket and interplanetary societies, France's society movement seemed almost entirely apart.

In 1945 Ananoff and Monier created the Astronautics Section of the University Aero-Clubs Association of France. With an imposing list of technical and scientific advisors and an editorial staff, some progress was made and four issues of the journal L'ASTRONEF were published. But, by late 1947, the section was dissolved, and again French rocketry at the society level foundered.

Since 1955 everything has changed. Leading French scientists, engineers and military authorities have joined together to form the French Astronautical Society, and the BULLETIN D'ASTRONAUTIQUE, of much higher caliber than previous society publications, is now published. In December 1956 a great International Congress of Rockets and Guided Missiles was held in Paris, where experts gathered from all over the world. A full-fledged journal FUSEES ET RECHERCHE AERONAUTIQUE has been appearing quarterly since June 1956, often more than 100 pages in length, with technical and semitechnical articles by French and foreign experts.

French Missile Developments

French missiles can be divided into six categories or missions. These include air-to-air, air-to-surface, surface-to-air, surface-to-surface, drone and special test vehicles, and upper atmosphere sounding rockets. Rocket-powered, manned airplanes will not be considered in this article. For ease of reference, many details have been placed in the accompanying charts.

Air-to-Air Missiles

The Matra M.04 is produced by Sud-Aviation and the Society Matra. It is 2/3 scale model of a development missile that has surface-to-air and air-to-air applications. An SEPR 2750-pound thrust rocket motor supplies thrust for 14 seconds on liquid propellants. It has all-metal construction, duralumin skin, and gyro-controlled aerodynamic tail vanes and

'Veronique' liquid propellant engine firing.

SNCA du Nord's CT.10, a thoroughly proven target plane recoverable by parachute.

French Missile Arsenal

Designation	Contractors	Agency	Velocity	Range/ Altitude miles	Weight lb.	Length ft.	Diameter in.	Powerplant	Thrust lb.	Firing Time sec.	Remarks
Air-to-Air Missiles											
M(AA).20	MATRA	Air Force	Mach 1-2	1		15		liquid SEPR	2755	14	For use on Mystere A, B. In production.
M.04	MATRA	Air Force	1118 mph		1015	15'1"	16	liquid SEPR	2755	14	Tested on Voutour, Grognard. Can be parachute recovered. 245 lb. payload.
M(R).051	MATRA	Air Force	Mach 1.5		350	9'10½"		solid			Used on Mirage, Voutour. In production. Solid booster.
M.510	MATRA	Air Force	Mach 1.7		350	9'10"					
M.511	MATRA	Air Force									Secret. Reportedly for use on Trident.
AA.10	SFECMAS, SNCA-N	Air Force									
1524	Sud-Aviation	Air Force									Tested at Colomb-Bechar; successful in destroying drones.
550	Dassault	Air Force						Viper TJ			LPR booster by SEPR.
5103	SFECMAS, SNCA-N	Air Force	Mach 2	3-6½	287	8'2½"	10	solid			Flown on Meteors, Mysteres, Voutours. In production. In-line solid booster. 57 lb. payload.
Air-to-Surface Missiles											
BB-10		Air Force									Radio controlled bomb.
1522	Sud-Aviation	Air Force									Also air-to-air possibilities.
.....	.....	Air Force									Rascal-type rumored.
Surface-to-Air Missiles											
Maruca	SNECMA, DEFA	Navy									
Masalca	SNECMA, DEFA	Navy									
M.043	MATRA, SNCA-N							ramjet			SEPR solid booster.
PARCA	DEFA	Army	Mach 1.7	14	2200	14.7		liquid			Ramp-launched. Uses four solid boosters.
SA.100	Dassault										
SE.1524	Sud-Aviation										
SE.4100	Sud-Aviation		Mach 0.8	7½	287			liquid			A test rocket with solid in-line booster.
SE.4300	Sud-Aviation		near Mach 1	12	2200		18	liquid			A training, Nike-type missile, boosted, 11.1' span.
4400	Sud-Aviation										
422	MATRA										
.....	Sud-Aviation	Air Force						liquid			Presumably the ultimate development of Trident, possibly making it a Bomarc-type missile.
Surface-to-Surface Missiles											
BTZ-411.01	BTZ	Army									Coleopter-like, bazooka-type, two-stage missile.
ENTAC	DEFA	Army	190 mph	1.3				solid			Cable-guided, antitank missile. In production.
Jericho											
Lutin	BTZ		280 mph	3	33	4.25	16	ramjet			Rocket boosted.
Ogre I (BTZ-412.01)	BTZ		600 mph	50	720	6.5	36	ramjet			Photo-reconnaissance missile, liquid rocket boosted.
SE.4200	Sud-Aviation		Mach 1	60-70	660	10		ramjet			Ramp-launched. Accurate. In production. Has two solid boosters.
SE.4500	Sud-Aviation										
5200	SFECMAS	Army									AT missile, wire-guided, range 6500 ft.
SS.10 (5202, 03)	SFECMAS, SNCA-N	Army	190 mph	1.24	35	2'10"	6.3	solid			Antitank, close support rocket. Hollow charge. Very accurate, wire-guided. In service use.
SS.11 (5210)	SFECMAS, SNCA-N	Army	430 mph	2		4		solid			Improved, longer-range version of SS.10. In production. Solid in-line booster. SS.22 version rumored.
Miscellaneous Test Vehicles, Drones											
910	Breguet		500 mph					none			Unpowered glide bomb test vehicle.
CT.10 (Arsenal 5.501)	SNCA-N	Navy	280 mph	30	1452	19'8"		pulsejet	396		Launched from solid rocket boosted carriage. Can be parachute recovered. Target drone, radio guided.
CT.20 (T. 5.510)	SNCA-N	Navy	560 mph	125	1444	17'8"	25	turbojet	880		Guided target drone. Flight time is 45 min. Can be controlled within flight path of ±1.6 ft., and can be landed with 0.6 mile circle.
ECA.20	ECA										Guidance test vehicle.
ECA.26	ECA										Guidance and control test vehicle.
ECA.27	ECA										Test vehicle, airplane structure.
EOLE.51	DEFA

Circle No. 48 on Subscriber Service Card.

is considered highly successful. Tests have been made at Sahara ranges since 1952, with aircraft like the *Grognard* and *Vautour* having fired it operationally. (It can be parachute-recovered.)

Matra production missiles include the AA.20 and the R.051, the former being liquid propelled, the latter solid powered. The M(AA).20 is carried by the *Mystère A* and *B* fighters, and is thought to be very accurate. The R.051 is a beam rider, incorporates a proximity fuse, is highly accurate, and features canard construction. It, too, arms the *Mystère*. Range is classified, but is believed to be considerable. M.510 has an optical guidance system and is a two-stage affair. M.511 may be used on the *Trident* rocket-powered airplane.

Another program pushed by L'Armée de l'Air is the SFECMAS 5103, built by Nord. Like the R.051, it incorporates a warhead effective over "plusieurs mètres de distance," armed by proximity fuse. It has a cruciform airfoil and is probably a beam-rider. With both a solid sustainer rocket and in-line solid booster, it flies with constant velocity from the time of booster *cutoff; Super-Mystères, Meteors* and *Vautours* are known to have fired it. Little is said about Sud Aviation's 1524 except that it is a development sponsored by L'Armée de l'Air and has been tested successfully. It is possible that the ASM 1522 development also has an air-to-air rôle.

Air-to-Surface Missiles

This is one category of missiles that the French apparently have not investigated thoroughly or at least, little knowledge of their work has been released. Some of their air-to-air missiles can double as ASMs, and such short-range surface-to-surface rockets as the SS.10 are fired from helicopters at low altitudes. The French Navy is now building a helicopter carrier that will not only be outfitted with defensive missiles but will have its helicopters armed with offensive varieties.

The BB.10 represents the latest of a series of guided bombs developed since the war and is used with the *Vautour* fighter-bomber. It features cruciform fins, an annular shroud wing and canard surfaces. The SNCASE (now Sud-Aviation) 1522 is a development about which nothing is known and it may not have been carried forward into operational use. France is rumored to have a *Rascal*-type ASM, but substantiating information is not available.

In effect, then, the French air-to-surface missile picture seems to show the use of small, high velocity rockets adapted from air-to-air use (a good example being SNEB rockets launched from Matra-type 116 pods carried by the *Vautour*), guided bombs, and, if you consider helicopters, SSMs launched from low-altitude platforms.

Later version of the SNCA du Nord CT.10, this CT.20 has greater speed than its predecessor, has been sold in quantity to foreign countries, notably Britain.

Surface-to-Air Missiles

French surface-to-air missiles are designed to fit in between classic air defense ground setups and the intercepter. Most models are in the tactical experimental stage. The leading types are the Sud-Est (now Sud-Aviation) 4300 and LRBA-DEFA's *PARCA*, which stands for Projectile Autopropulse Radioguidé Contre Avion.

Sud's 4100 is a liquid-sustained, solid-boosted experimental type which led into the 4300. Nothing concrete has been given out on the Navy's *Masalca* and *Maruca*.

PARCA has a range of about 12 miles, perhaps 14 at the most, and can bring down a plane flying at an altitude of six miles. It is a beam rider, and the warhead is detonated by proximity fuse. *PARCA* was developed with the aid of LRBA at Vernon, EET-V, l'Atelier de Constructions, Puteaux and EET-B which handled test firings in both France and Colomb-Bechar. Cruciform canard controls are featured with delta fins. The French say little more about 4300 save that its performance is "sensiblement anologue" to that of the American *Nike*, is cruciform type, with no tail, and 45° sweep back. Thrust from its liquid rocket can be regulated. It is now used to train Army guided-missile personnel.

The possible eventual use of the *Trident* rocket-powered airplane as a SAM will not be discussed here, but reserved for a later article devoted to the rocket airplane.

Surface-to-Surface Missiles

Most significant French SSM research has centered on the antitank weapon, with notable success. Both the Army and Air Force have participated in these developments, the latter being interested in the helicopter-to-ground versions as noted earlier.

Within the SS.10 program are the SFECMAS 5200 (Nord) series* and DEFA's *Entac*, both with nearly identical ranges and velocities. They are wire guided, solid propelled, and have shaped charges able to pierce thick tank skins. The 5200 saw action in the Israeli war against Egypt with good results. Commands are relayed along wires, which unwind under the wings. The *Entac* version is now entering production.

SS.10 is highly accurate and needs only a few men for effective operation. Tests made in Colomb-Bechar, North Africa, have been described as 98 per cent accurate. The American Army has adapted the design to its own use.

The French have fired this missile from their SO.1221 *Djinn* and *Alouette* helicopters. Normally, three are carried on a launcher on each side. They have also reportedly been fired from the Dassault 315 *Flament* twin-engined transport and from the Potez 75 tactical support airplane.

The SS.11 (SFECMAS 5210) program is a longer-range version of SS.10 and is under large-scale production for the Army and Air Force. Other than surface-to-surface and air-

** The 5202 is the training version, and 5203 is the operational version.*

to-surface applications, it may be tried out in an air-to-air role. Solid-propelled, an eventual ramjet version is rumored.

Other French SSM projects include Zborowski's BTZ-411.01 bazooka-type missile, his 33 pound *Lutin* army infantry ramjet and the *Ogre 1* long-range photo-reconnaissance ramjet, with liquid rocket booster. This latter is tailless, with barrel-type coleopter rings.

The only moderate-range vehicle known to be under development in France is the SE.4200, which was originally developed by SNCASE (now Sud-Aviation) under the direction of the Direction Technique et Industrielle de l'Aéronautique. Army's Section Technique later tested it and brought it into service. Designed to carry a powerful charge to distances of 60 or more miles, it is launched from a truck-mounted ramp by a solid booster (which drops upon cut-off).

The charge is carried beneath the missile in a pod. It is gyro-stabilized, attitude being maintained by wing-tip controls and elevons. An altimetric device controls altitude. It is hoped that this tailless guided missile will graually replace long-range artillery. There are only rumors of longer-range SSMs under development in France.

There are a number of experimental. test vehicles in France as well as several drones. The Breguet 910 is an unpowered glide bomb which is released from an airplane at 15,000 feet, to glide to the target at subsonic speeds.

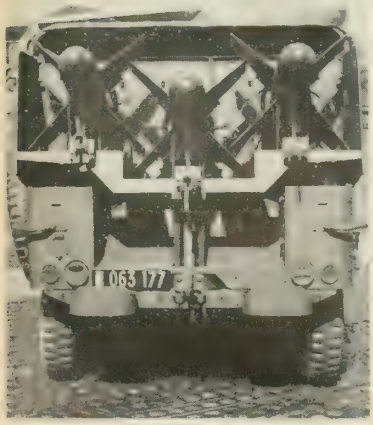
This is unusual in that it has prestressed concrete wings. ONERA of Châtillon developed an OPD.320S experimental telemetry test rocket which could carry up to 100 pounds of parachute-recoverable instrumentation. SNCA du Nord has a CT.10 (ARS 5.501) guided target plane that has been thoroughly tested and used, plus an advanced CT.20, both recoverable by parachute. The former uses an Arsenal pulsejet, gives 396 pounds of thrust, and has seen service with the French and British navies. Ramp-launched by two powder rockets on a carriage (recovered after separation by parachute), it is radio controlled and has an auto-pilot.

Should the CT.10 fall in the water, it will float until pickup and, like the *Skokee*, it has a spike in the nose for land recovery. The French use it for antiaircraft artillery and surface-to-air missle training. CT.20 is much like the .10, has a turbojet engine, and is considerably faster. Both have been sold abroad, notably to the British. The Eole-51 was an experimental, fin-stabilized rocket used by DEFA as a test vehicle for *Veronique*. Operating on liquid oxygen and alcohol, it featured sheet-metal construction. The Société SAGEM constructed the missile, and two were fired by CIEES, Colomb-Bechar, in 1952.

ECA. 20, 26 and 27 are all guidance and control test vehicles. The SFECMAS-Nord ST.450 is ramjet powered, solid rocket boosted, and can be parachute recovered.

Atmospheric Sounding Rockets

France has two entries in this field, the *Monica* ATEF-14 and the *Veronique*. The former comprises a series of two- or three-stage solid-propelled rockets, and was named for the daughter of an engineer who worked on the missile. (She was born on the day of the first firing.) It is a low-cost rocket, and, depending on the type and payload, can fly from 55 to 90 miles high. Backed by the Ministère de l'Air, some 15 are expected to be fired during the 1957 part of the International Geophysical Year. Experiments involving cosmic ray and atmospheric physics are performed by *Monica*. A 4-6 channel, AM/FM telemetering system is used.



The *Veronique* holds, as far as is known, the European altitude record of 84 miles, established with rocket NA-14 in February 1954. The missile has variously operated with WFNA and diesel oil or furfuryl alcohol or oil of turpentine, the last being used in the record performance. DEFA, through LRBA, developed *Veronique* in 1949, and it is still undergoing development and modification at the Vernon facility.

Probably the most unique feature of *Veronique* is its intitial stabilization system, which consists of four unwinding cables extending from outriggers attached to the missile. When speed and altitude have been gained, the outriggers are explosively detached, and *Veronique* continues upward, now stabilized by her aerodynamic surfaces.

The first vehicles were fired in 1950, and since that time a number of changes have been introduced.

Veronique's telemetering system can transmit 20 measurements; carrier frequency is 152 m/c; time modulation is converted at the surface station to amplitude modulation; and some 35 information bits can be transmitted per second

New *Veroniques*, the first since 1954, are now being constructed, and by the time this article is printed the first may be ready. Difficulties with the telemetering system, however, may prevent firings until late in the year or early 1958. ★

The outstanding antitank missile, SS.10.

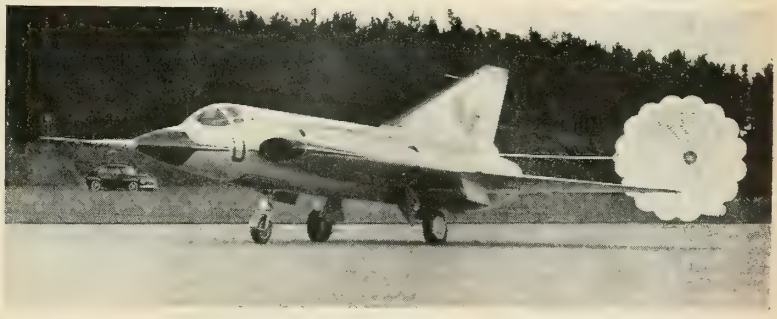
International editor for m/r, Anthony Vandyk, examines instrumentation package in Paris.

SWEDEN . . .

From Torpedoes to Antiaircraft Missiles

by Frank McGuire

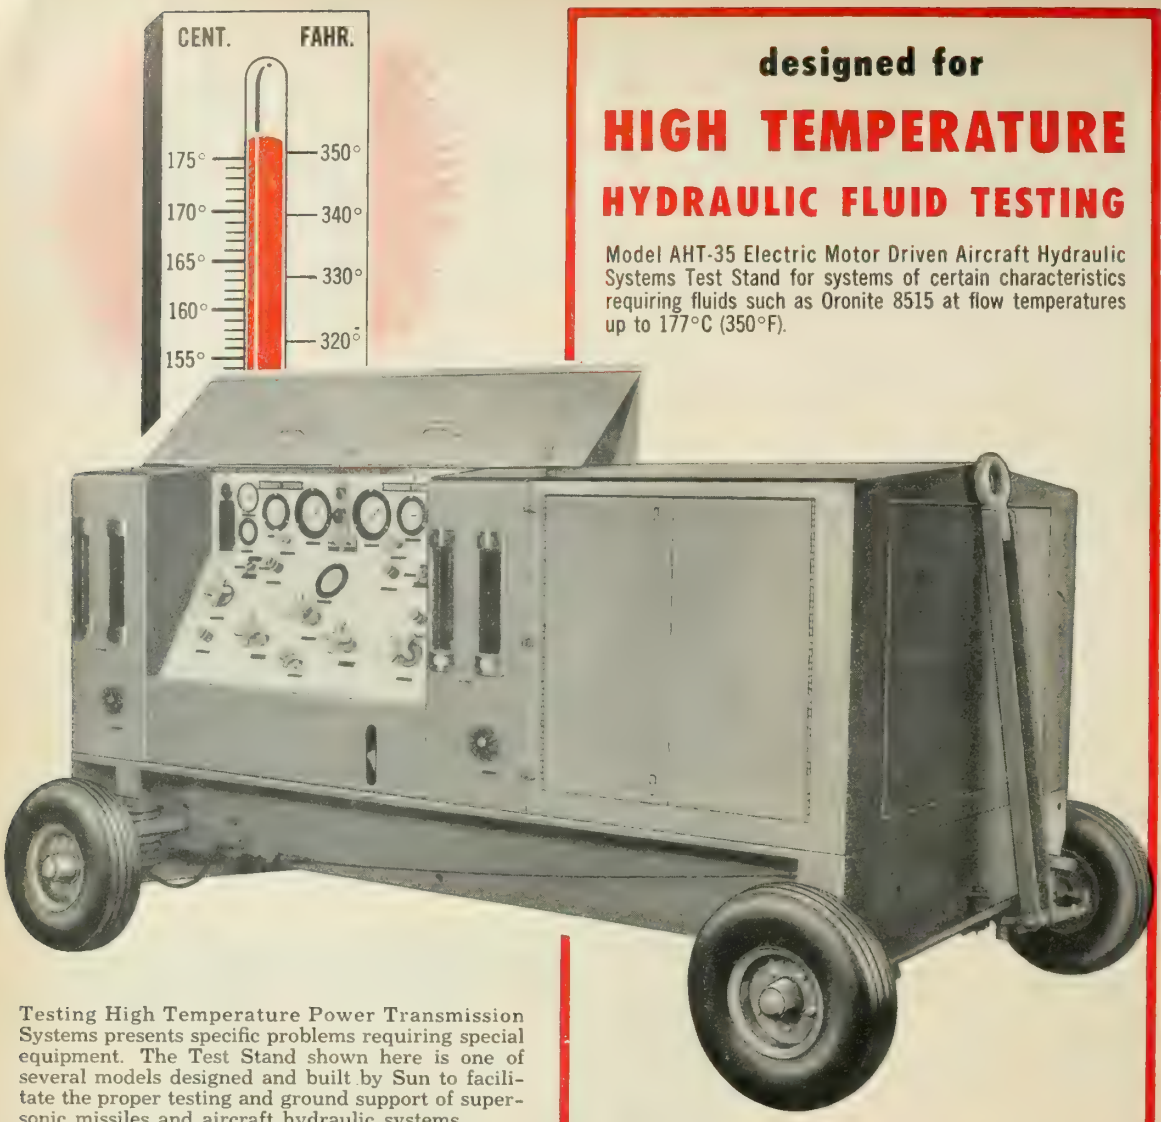
THE MAIN EMPHASIS in Sweden's missile program appears to be on SAMs and missiles for coastal defense. Work has been underway on other types for some time, but not with the high priority placed on aircraft-interceptor missiles in the *Bomarc* and *Nike* classes. Surface-to-surface missiles for naval use have been under study, but application of these to land operations has not been pushed.



Since 1955 the Swedish Air Force has had under development an interceptor known as *Luftforsvarsrobot,* which is of the *Bomarc* class and capable of very high altitude interception at ranges from 120-150 miles. Other, smaller, missiles are also being developed for antiaircraft defense and some are undoubtedly operational.

Sweden's total missile industry activity includes many areas, but not ICBMs, and puts little dependence on foreign production. An exception to this, however, is the September purchase of ten *Jindiviks* from Australia. Another type drone is being produced by A. B. Flygmal Co.

Bofors has developed a guided AAM for use on the J35 interceptor. The Saab A32 *Lansen* all-weather attack aircraft is also equipped to handle Swedish-developed AGM for tactical strikes. One of these aircraft rockets is the *Jaktrobot* (fighter missile), which is due to become operational soon, as is the *Sjorobot* (sea missile) for naval surface-to-surface use.



The Swedish missile industry is also pushing research on ramjets, high-energy fuels and advanced rocket designs. Their propellant materials production is quite adequate for supplying the blossoming missile program. ✶

Swedish army troops (top) will be supported by tactical missiles like those fired from the SAAB DRAGON, J35 (center). The latest torpedo boat design, the T101, may be equipped with missiles and guided torpedoes.

designed for

HIGH TEMPERATURE

HYDRAULIC FLUID TESTING

Model AHT-35 Electric Motor Driven Aircraft Hydraulic Systems Test Stand for systems of certain characteristics requiring fluids such as Oronite 8515 at flow temperatures up to 177°C (350°F).

Testing High Temperature Power Transmission Systems presents specific problems requiring special equipment. The Test Stand shown here is one of several models designed and built by Sun to facilitate the proper testing and ground support of supersonic missiles and aircraft hydraulic systems.

Sun's unrivaled experience in the development of this and other types of aeronautical and astronautical testing equipment, is recognized by leading airframe and systems contractors.

Perhaps you have a problem involving the testing of high or low temperatures and pressures; hydraulic, pneumatic or electrical-electronic systems. Sun can offer you complete and invaluable assistance in its successful solution.

Write today or mark the Reader Service Card for more information.

SPECIFICATIONS

Model AHT-35	Electric Motor Driven
Model AHT-37	Gasoline Engine Driven
Type	Mobile, Dual system, self-contained, trailer mounted
Dimensions	120 in. long, 68 in. wide, 66 in. high
Weight	Approx. 6700 lbs. (dry)
Fluid Flow	25 gpm each system @ 3000 psi
Fluid Temperature	177°C (350°F) Oronite 8515
Operating Temperature	—18°C to 60°C ambient
Operating Altitude	Sea Level to 5000 ft.
Model LAHT-37	Gasoline Engine Driven

JAPAN . . .

From Research Rockets to Missiles for a New Army?

By Frederick I. Ordway III

JAPAN IS WORKING hard to enter the forefront of missile and space-flight sciences. Activities center around three main areas of endeavor: (1) military rocketry, (2) research rocketry, (3) space flight planning.

Tokyo newspapers have made much of recent Japanese efforts to provide the country with adequate missile defenses. The Japan Defense Agency is hoping to legislate a defense secrets preservation law which will permit full production of guided missiles in Japan under license from foreign countries.

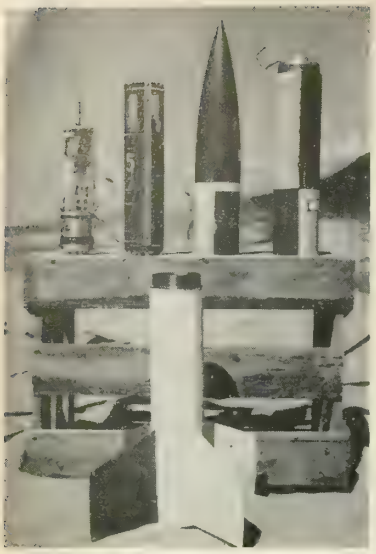
Japanese authorities point out that *Nike* and other American types could be employed if there were an adequate security protection system in their country. The government is not, however, limiting its considerations to American rockets, and has expressed interest in Italian (Polverifici Stracchini, S.A. will supply 500 Airone AAMs) and Swiss developments.

The Mitsubishi Electric Machinery Co. has concluded an arrangement with Switzerland's Oerlikon Machine Tool Works Buehre & Cie, whereby Japan will receive patent rights to produce the *Oerlikon-56* SAM and launcher. The contract covers an agreement with Contraves AG of Zurich, an Oerlikon affiliate, which produces missiles and fire control equipment. This has been done under the current equipment modernization program, and should provide Japan with some missile defense by 1959.

If Mitsubishi gets permission from Japan's Foreign Exchange Commission, it will pay 18-million yen (half a million dollars) for patent rights. Oerlikon wants eight per cent patent rights for the *-56* and five per cent of sales of launching and fire control equipment.

Sources close to the Defense Agency believe that during the next few months Japan will purchase a complete *Oerlikon-56* rocket launcher setup for the purpose of making careful studies of the system. Mitsubishi Electric, Mitsubishi Shipbuilding and Engineering, Mitsubishi Heavy Industries, and Mitsubishi Chemical Industries will cooperate in the Japanese missile program.

It is interesting to note that Yasjiro Okano, the liquidator of the old Mitsubishi Heavy Industry Co., has been named chief of the Guided Missiles Council, which effects liaison between industry and government.



Pilot production of the first Japanese guided-AAM is expected to get under way by 1959. The missile will be in the *Sparrow* class. By 1960, the Japanese expect to begin production of a *Nike*-type missile for ground-to-air use. The model TMB-0, a radio-controlled test missile, was cancelled after two unsuccessful tests. The TMB-0 was 5'4" long, with a swept-wing span of almost 3 feet. Launching speed was about 410 fps.

Missiles will change Japan's self-defense force.

Research Rocketry

Recent attention has been given to Japanese rocket research (m/r Oct. 1956; JET PROPULSION, March 1957).

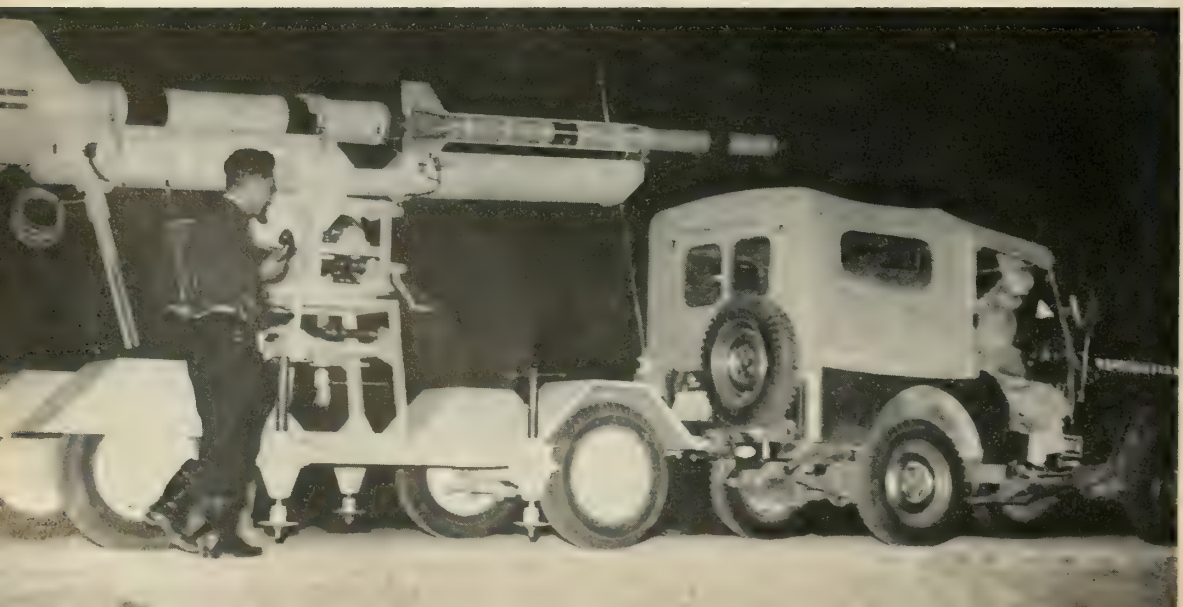
The Japan *Rockoon* Committee, in a meeting at Ritkyo University, announced that 30 balloon-launched rockets will be fired during the I.G.Y. They will be released for cosmic ray, ionospheric, and solar radiation research. Three of these will probably be fired from the ship *Ryofu Maru* in the Pacific in August. Besides *Rockoons*, Japan will fire 50 additional I.G.Y. rockets. Some of the pre-I.G.Y. Japanese *Rockoon* tests have been successful. The first left the *Ryofu Maru*, located off the Boso Peninsula (Chiba, Japan) in April, but failed completely.

The second, however, was successful. Eight rubber balloons, each filled with 800 grams of hydrogen, lifted the 3.95-foot-long rocket at a velocity of 985 feet/sec. Firing took place at 65,500 feet, and the rocket reached a peak about 50 miles west of the launching ship. Longer *Sigma*-type rockets will also be used to reach up to about 68 miles.

Japan's surface-launched research missiles include the *Kappa-3* and *Kappa-4*, and *Kappa-5*, two- and three-stage vehicles, respectively. Firings have taken place from Michikawa Beach, where the Tokyo University Rocket Research Center has a test facility. Launched at an angle, *Kappa-3s* have a top speed of Mach 3.7, a firing time of 143 seconds and a range of about 20 miles.

A successful Japanese *Rockoon* test was made at Tateno, near Tsuchiura, Ibaragi-ken, in which cosmic ray experiments were carried out. This rocket was 3.94 feet long, and carried both a Geiger counter and a telemetering device. *Kappa 3* successfully fired at Michikawa Beach, soaring to about 15 miles. It was 16 feet long, and weighed 320 pounds. It was sponsored by Tokyo University.

Kappa-5s, which will be fired in support of the I.G.Y. in October of this year, reach about 80 miles. An intermediate rocket, *Kappa-4*, is 16 feet long and can attain Mach 5 velocities, soaring to some 40 miles.



It has been announced that Japan will buy, in addition to its own rockets, five U.S. *WASP*-type rockets to be launched from balloons.

Space Flight

That the Japanese are astronautically minded was made clear by F. C. Durant (m r, Oct. 1956 and Nov. 1956) last fall. The YOMIURI JAPAN NEWS (Tokyo) advises taking off for Mars if (1) life is getting you down and (2) you don't know what to do with the extra money you have in your pockets because of income tax cuts. Sensitive to atomic bombs, the paper goes on to point out an advantage of Mars: ". . . the air (if there is any air) is not already contaminated by radioactive fallout."

In a more serious vein, the Japanese scientists are taking a long look at earth satellite plans. The head of Tokyo Astronomical Observatory and of the Japanese Chapter, Earth Satellite Committee, has recently toured America and Europe and has announced that Japan would be provided with a Schmidt astronomical camera for satellite observations. Earth satellite observation units have been practicing regularly, and feel they are ready to do their part in the world-wide observation program. ★

ITALY . . .

NATO Missile Effort Off to Slow Start

By Franco Fiorio

IN THE 12 YEARS since the end to World War II, there has been a lot of interest in Italy in the rocket field, by individuals, government and private research groups. Unfortunately, both lack of funds and a coordinated effort by industry, in addition to the absence of a clearcut government program, have resulted in a serious delay in developing the Italian potential in rocketry.

The top government agency in charge of rocket development is the CORAMI (Comitaye Razzi & Missile), a joint group headed by Air Force Lt. Gen. Casero and working directly under the Chairman of the Italian General Staff, Gen. G. Mancinelli. CORAMI, in addition to its planning and programming activities, coordinates the rocket research and development effort of the three services and regulates the use of the new defense rocket and missile test range.

Military security is clamped tight on the research and testing work on the new test range, operated by the Italian Air Force.

Three civilian agencies are also involved in rocket development: SISPRE (Societa Italiana Studio Propulsione a Reazione), a research and production group sponsored jointly by the Italian Dept. of Defense, the Fiat, Finmeccanica and Bombrini-Parodi companies. Former Air Force Chief of Staff, Gen. A. Urbani, ret., is president and general manager is Professor Ing. Matteini, an electronic specialist.

The SISPRE group is looked upon as a potential link between the government and industry for the development of future weapon systems, in a role similar to that of Ramo-Woolridge in the U.S.A.

AIR (Associazione Italiana Razzi) is the Italian Rocket Society, active in the theoretical field and functioning as a representative of the profession. President is Professor Gen. G. A. Crocco and executive Vice President is Dr. A. Eula, Professor of Aerodynamics at the University of Rome.

CAAI (Centro Aeronautica & Atomico Italiano) is a private, nonprofit organization, sponsored by a group of members (260) of the Italian Parliament, by industry leaders, members of the government and independent scientists. It attempts to disseminate basic information on aviation and nuclear matters and to trigger an increase of interest and activity in the studies and production of advanced air vehicles, among them, rockets and missiles. President is the Hon. F. A. Di Bella, Congressman from Sicily; acting Secretary is Dr. G. Partel.

Research and Development

Several companies and private groups are active today in rocket research and development. There is a substantial number of engineers working on individual ideas, but here again lack of funds and coordination are the main obstacles to the achievement of practical results.

The following are some of the most important research groups:

CESPRE (Centro Studi Propulsione a Reazione) is the research branch of SISPRE headed by Gen. Urbani. This group is by far the most important in Italy and is now working on the air-to-air infrared solid-propellant missile C-7 and other classified projects.

Contraves Italiana is the Italian subsidiary of the Swiss company by the same name, which is part of the Oerlikon group. This company is developing a later model of the surface-to-air liquid-propellant missile, well known in the U.S. where it was introduced some years ago by Oerlikon Co.

BPD (Bombrini Parodi Delfino) is the largest Italian manufacturer of ammunition, explosives, and propellants, producer of the standard solid-propellant (bibase-ballistite type-M7) used by the Italian services. BPD is now conducting classified research in the field of solid propellants of improved characteristics.

Stacchini Co., formerly a producer of TNT charges for aircraft bombs, has entered the rocket area, in cooperation with Italjet. In the past years it has developed a family of unguided rockets of many types, powered by the standard BPD bibase solid propellant. None of these went beyond the testing stage. Only exception is the order from Japan for the *Airone* rocket, a cheap, solid-propellant (BPD) surface-to-surface unguided missile. Range of the *Airone* is reported to be over six miles. No other data are available. In addition to this activity, the Stacchini Co. has also sponsored research work on experimental rockets designed by Prof. Salvadori of the University of Rome.

Contin Co. is a small activity beyond the outskirts of Rome engaged in an experimental project on a small liquid-propelled research rocket. The

Globe Aerostatique . . . 1783

Montgolfier's vanguard project

A sheep, a duck, a rooster—the first payload carried aloft for atmospheric research. Louis XVI, his queen and his court, were astonished witnesses as Joseph Montgolfier's smoke-filled balloon rose in majesty 1500 feet over Versailles. The passengers? unharmed (except the rooster, kicked by the sheep).

Project Vanguard, 1957, is an equally momentous "first"—an attempt to place a 21-pound satellite in an orbit 300 miles up. Aerojet-General, designer-builder of the famed Aerobee-Hi, will supply vital second-stage propulsion systems for Vanguard launchings during the International Geophysical Year.

Aerojet-General CORPORATION

A Subsidiary of The General Tire & Rubber Company

THE GENERAL TIRE

PLANTS AT AZUSA AND NEAR SACRAMENTO, CALIFORNIA

Aerojet-General invites scientists and engineers—men of imagination and vision—to join the attack on the most significant research, development and production problems of our time.

rocket was designed by Dr. Sivori of the University of Rome, under the supervision of Italy's leader in Italian rocketry, Gen. Prof. G. A. Crocco.

Motofides S.p.a. in Livorno, part of the Fiat group and manufacturer of torpedoes for the Italian Navy, has been sponsoring a research project headed by Dr. Ing. A. Robotti. The project has designed a series of liquid-propelled, surface-to-air rockets of clean configuration and fair characteristics. The propellant is nitric acid and aniline. Design emphasizes low production costs and ease of maintenance and operation. An experimental order for an undisclosed number of *Robotti* unguided rockets and launchers has been awarded to Motofides by the Armed Forces. Diameter of the rocket is 40-50 in. and the length 15-16 ft. Speed is supersonic.

Boscari Co., headed by Dr. Ing. F. Salvini, one of the little known but outstanding pioneers of the Italian rocketry, boasts several interesting developments. Among them is a patented new type of multibase solid propellant, designated S-I, with excellent stability, low hygroscopic sensitivity and high shock resistance. Its low combustion pressure (1/3 of the ballistite type propellant's pressure, at equal volume and temperature) affords substantial savings in the structural weight of the combustion chambers.

Other Boscari developments include an underwater fishing rocket gun and a fragmentless plastic Bazooka practice head, capable of registering hits in color on the target. In cooperation with the Hispano Suiza Co. and the Italian Industrie Meccaniche Napolitane (INM), the Boscari Co. has developed a *Katyuscia* type of multibarrel (20) rocket, designated HSS-R 80/100, which has since been adopted by the Dutch and Egyptian Armies.

Production Facilities

Only a handful of firms are currently producing rockets in Italy on a mass production basis.

BPD (Bombrine Parodi Delfino) makes *Scar* 2:75-in. airborne practice rockets for the services. Boscari is subcontractor for the practice head.

Boscari makes standard bazooka practice rockets with plastic heads for the Italian Army. Subcontractor for the solid propellant is BPD.

Italjet, a group formed by the Stacchini, Motofides and Aerojet-General, make JATO units for NATO offshore requirements.

Despite this token activity, there are several indications, including a renewed interest by the Italian Defense Ministry, that the rocket business will increase substantially within the next few years in Italy, both in the research and in the production fields. ★

One tape can't serve all recording needs in magnetic instrumentation

There are differences between pulse and carrier recording . . . therefore the tapes used in these systems must have different characteristics. Only in Soundcraft Instrumentation Tapes are these distinct and separate properties engineered into the oxide formulation. Soundcraft then adds two original processes — Uni-Level Coating and Micropolishing — to achieve the surface perfection found exclusively in the most advanced tapes of our time:

Soundcraft Type A Tape for Digital Recording

Soundcraft Type B Tape for Telemetering

Get the Soundcraft Tape that's made for your application . . . get error-free recording!

RCCH oxide formulation gives "Type A" higher signal output and greater retentivity plus unique surface hardness for controlled tape wear rather than uncontrolled equipment wear.

The special FM formulation in "Type B" is a highly refined form of gamma Fe_2O_3 oxide with high temperature binders, lubricants and antistatic agents to assure uniform speed and tape-to-head-contact — preventing flutter.

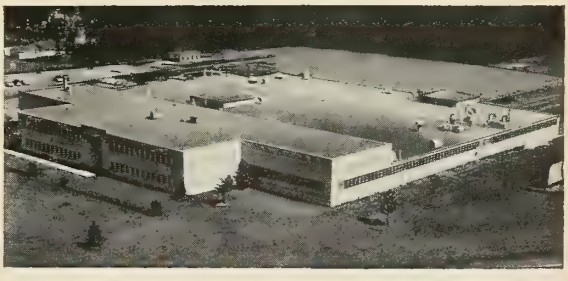
A NEW AIRCRAFT PRODUCTS PLANT...
THE LELAND ELECTRIC COMPANY
Division of
AMERICAN MACHINE & FOUNDRY COMPANY

AT AMERICA'S AVIATION CROSSROADS



At Vandalia, Ohio, the Leland Electric Company has brought together under one roof, a complete research, development and production facility for aircraft electrical accessories.

Here highly trained personnel with widely diversified skills meet the thousands of complex problems that arise in the manufacture of precision aircraft products.

Within this air-conditioned plant's 140,000 square feet . . . a Model Shop with the most advanced equipment . . . a wide range of modern, highly accurate Environmental Testing facilities . . . a special "Short Order Shop" to smoothly absorb the low activity of an aircraft contract in its early production stage.

The increasing demand for Leland Aircraft Products "built" this plant. Tried and proven Leland products of today . . . and history-making Leland products as yet unknown . . . will be produced here. Today, tomorrow, why not meet *your* contract needs through Leland?

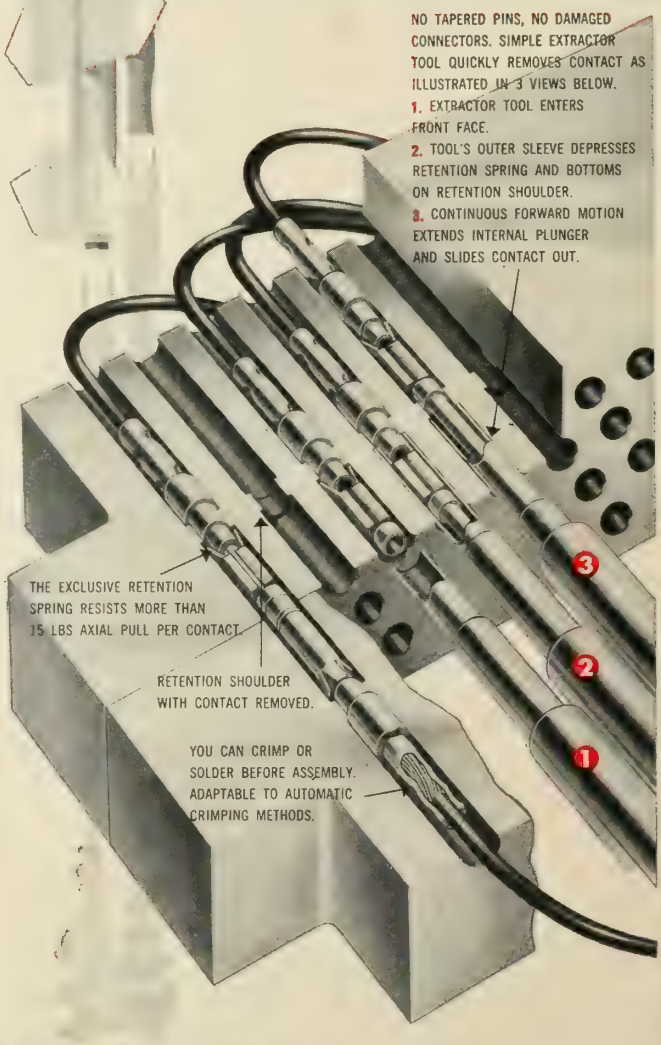
Another CEC first...



a new rectangular connector with exclusive

snap-in contacts

First in the field, CEC's exclusive snap-in contacts *lock* in place, yet can be removed quickly, easily as illustrated. The advantages of this new concept are unexcelled: Wire can be attached to contacts by crimping or soldering before assembly. You can capitalize on semi- or fully automatic crimping methods. Pins and sockets are interchangeable in the same connector body. Exclusive split hood is rigid, has fewer small parts, speeds assembly, facilitates inspection. You make *big savings* in time and money, drastically cut assembly and field maintenance costs.

MEETS MIL-C-8384A Specifications. Also physically interchangeable and will mate with ordinary connectors having similar contact arrangements.

EVALUATION UNITS available from stock in October —*Order now*. For complete information, write today for BULLETIN CEC 4004-X6.

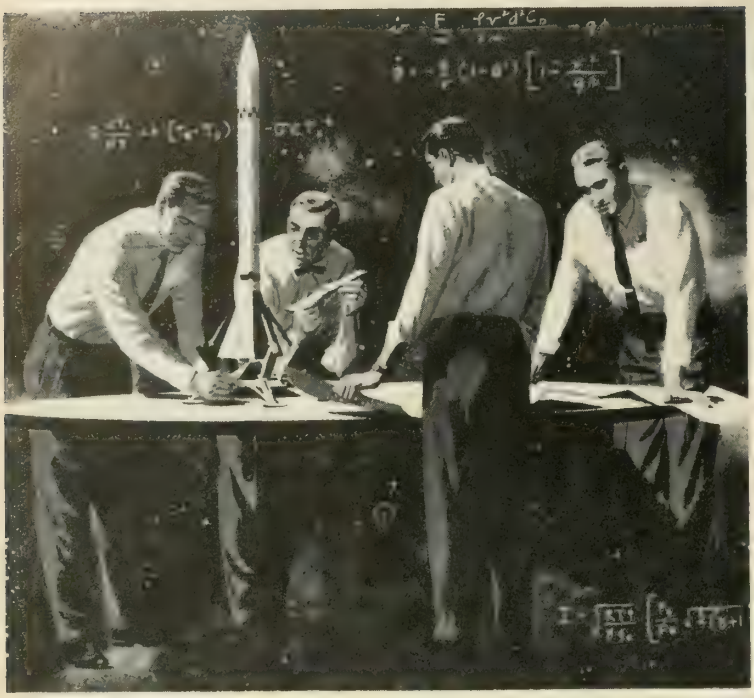
Missiles for NATO

Ordnance Guided Missile School Trains NATO Personnel

By Norman L. Baker



THE U.S. ARMY Ordnance Guided Missile School of Redstone Arsenal, the Army's only activity devoted exclusively to guided-missile training, has taken on the international look in recent months. Since the school was formed in 1952 students from this nation's armed forces and from five foreign nations have received training at the school.

Students from NATO nations are the latest addition to OGMS. First

LEFT—OGMS Corporal instructing group of Italian officers during class in NIKE-AJAX familiarization. BELOW—MISSILES AND ROCKETS editor Norman L. Baker interviews Maj. Ejvin Larsen, 1st Lt. Herman Dangaard and Lt. Bert Okholm, part of the initial contingent of personnel from Denmark to enroll at OGMS. The first Danes and Norwegians are receiving training to qualify them as interpreters for the main body of students.

IMPORTANT DEVELOPMENTS AT JPL

Teamwork in Missile Development

The Jet Propulsion Laboratory provides a wide range of research and development activities. Projects include problems in the fields of Electronic, Mechanical, Aeronautical, Chemical and Metallurgical Engineering, Physics and Mathematics.

The fluid character of these activities provides a keen incentive to JPL engineers and scientists. These men are given wide latitude and unusual individual responsibility—at the same time working as a thoroughly integrated team on all aspects of entire missile systems rather than on certain highly specialized missile components.

JOB OPPORTUNITIES NOW IN THESE FIELDS . . .

PASADENA • CALIFORNIA

foreign students to be enrolled were from Great Britain and Canada. The first British class graduated in March 1956. This year students from Norway, Denmark and Italy have enrolled in the first step toward initiation of the NATO training program.

The first of the NATO personnel are comprised entirely of officers carefully selected from their country's armed forces. Representing only a handful of the NATO personnel that will eventually be trained at OGMS, the first groups will later be utilized as interpreters and instructors for the personnel that will follow.

NATO training is currently concentrated on the *Nike-Ajax* surface-to-air missile. This training is restricted to the supply, repair and maintenance aspects of the missile system. The operational phase of training is conducted at Fort Bliss, Texas. Later, the units trained at Bliss and OGMS will be merged into complete missile-systems units and will receive additional instruction before returning to their home countries.

With the exception of two officers, all personnel interviewed by m/r editors are being exposed to guided missiles for the first time.

Although none of the officers were volunteers, when ordered to leave their homes and attend the OGMS they expressed eagerness for the assignment. Most are married and are living with their families in homes around the Huntsville area. Morale is very high, apparently due to enthusiasm for their assignments and for the opportunity of visiting the U.S.

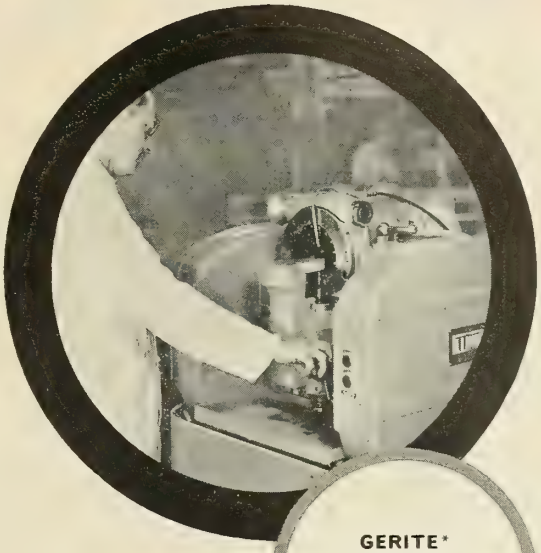
A per diem payroll allotment puts

1st Lt. Domenico Loda and 2nd Lt. Virgili Luigi of the Italian Air Force, students at OGMS, who were impressed by the NIKE-AJAX.

Officers of the Italian Air Force probe the "insides" of a NIKE-AJAX surface-to-air during a class in repair and maintenance.

the NATO officers salary on a comparable basis with that of the U.S. officer. This has avoided a compromise in their standard of living. A minor complaint of the officers was the lack of those foods that can be found in abundance only in their home countries. Several of the trainees have made previous trips to the U.S. and have had only minor difficulty acquainting themselves with our customs.

The NATO personnel are taking the same courses as the American students with the same completion date scheduled. The basic prerequisites for the NATO students are identical to U.S. Army personnel requirements, with the additional stipulation that they have a general knowledge of electronics and mathematics.



The Italians, latest group to enroll, are all Air Force personnel. In Italy the Air Force has complete jurisdiction over all guided missiles. Three major branches of the Italian Air Force are represented in this class—flying, service and engineering. All have technical backgrounds: some are thoroughly trained in electronics and others in radar. A notable feature of the officers' background is that all are in a career category and have expressed the desire to continue their profession in the guided-missile field.

The first groups of Norwegians and Danes are here primarily as interpreters. They are serving a dual purpose in being here. When finished with their present courses, they will remain as interpreters for the main body of students due to arrive in the next few months.

On returning home, these men will hold a unique and respectful position in their countries' armed services. The Netherlands may be the next NATO country to send personnel to OGMS for training. These men will be technicians from the Dutch Air Force selected for training in the *Nike-Ajax* system.

There is no doubt in anyone's mind

NEW
FINE PITCH
GEAR ACCURACY

GERITE*
Gear Generating Machine
Remarkably accurate,
extremely versatile,
ideal for short runs.

Faster, more accurate Fine Pitch Gear production and quality control with these 4 Illinois Tool Works developments

Get higher standards of accuracy, reduce rejects and avoid wasted production and inspection time with this new ITW team in your plant. GERITE (above) —this machine permits tooling up and producing gears overnight! MICRITE*—for the first time an analytical check of fine pitch gear involute profile. MICRAC*—automatic charter utilizing precision ground master worm. Accurate to .0001, ideal for production checking. GEAR ROLLING INSTRUMENT—provides extreme accuracy and economical inspection on the production line.

(*Trade Mark)

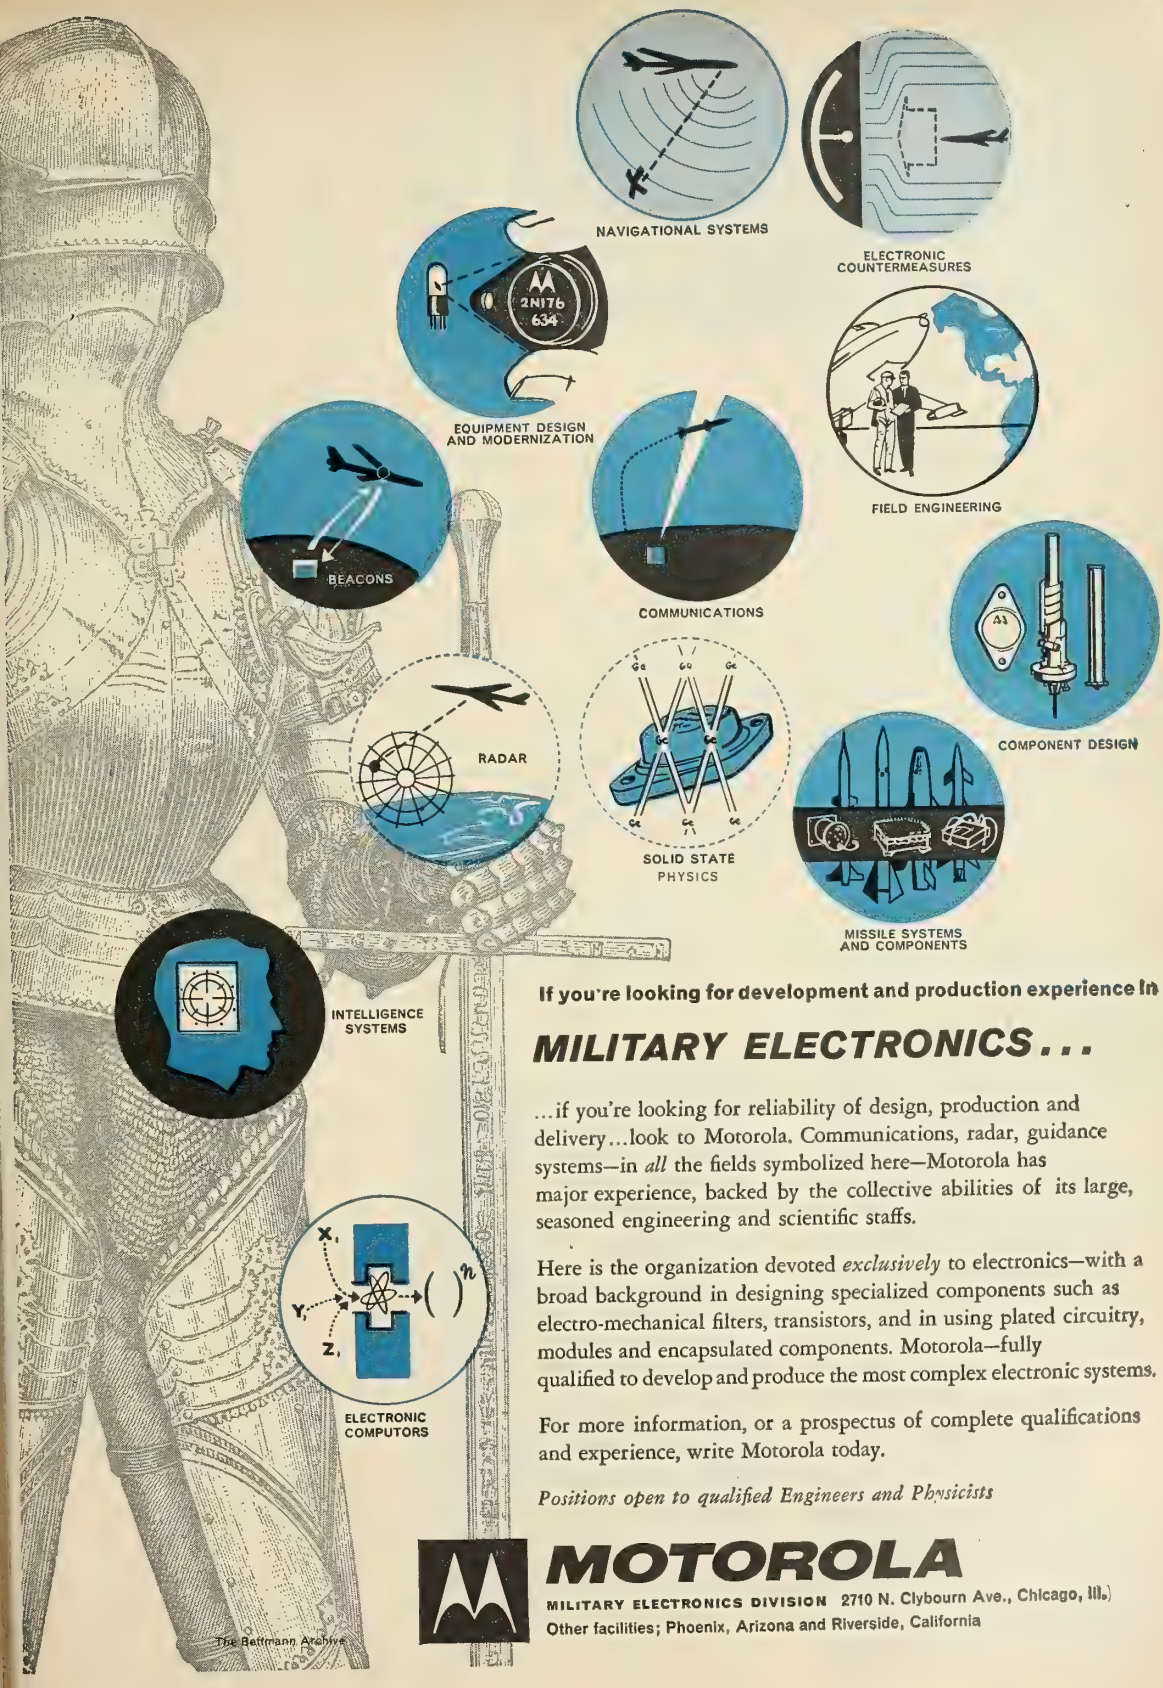
at OGMS that the NATO training operation can be anything but a complete success. Minor language difficulties, which will be eliminated when the interpreter staff is trained, are compensated by the enthusiasm and dedication expressed by the NATO students.

One of the instructors stated, "The NATO students are constantly looking ahead, staying one step ahead of the instructor, anticipating the next move. The students utilize the full time allocated when taking exams. They weigh every possibility on each question and then constantly review their decisions."



NATO training at OGMS currently comprises only a minor portion of the school's facilities and enrollment. OGMS has more than doubled in size in less than two years and is expected to double again in the next year. Total strength of the school stands just under 1750 persons compared to less than 800 in July 1955. Present number of students in training is in excess of 500 as opposed to 282 in July 1955 and 348 in July 1956. The remaining number make up the permanent party of staff, faculty, office, advisory personnel and the Unit Training Center staff. UTC is a division of OGMS devoted to training completely formed military units.

Personnel figures also include nine civilian contracting firms located on the base. OGMS employs approximately 100 field representatives from Philco, RCA, Firestone, Gilfillan, AASLI, Douglas, Western Electric, Chrysler, and North American.

OGMS now conducts 23 courses of instruction on the *Nike-Ajax, Corporal,* and *Redstone* missile system. Five units are currently undergoing training in the Unit Training Center. Plans are being formulated for adding the *Nike, Hercules, Dart,* and *Lacrosse* missile systems within the near future.

In preparing for the increased training load that will follow as a result of the addition of new missile systems, OGMS is in the midst of a $15-million building program. The construction program includes three class and laboratory buildings, two shop buildings, a technical library, a training aids shop, a special electronics-maintenance shop, and a special wheel vehicle maintenance shop.

Col. Henry S. Newhall, Commandant of OGMS, commenting on the present expansion program, stated, "These facilities will provide for new missile systems as they are developed by the Army. For, as new systems are added to the Army's arsenal of long range weapons, additional courses will be added to the school." ★

If you're looking for development and production experience in

MILITARY ELECTRONICS . . .

. . . if you're looking for reliability of design, production and delivery . . . look to Motorola. Communications, radar, guidance systems—in *all* the fields symbolized here—Motorola has major experience, backed by the collective abilities of its large, seasoned engineering and scientific staffs.

Here is the organization devoted *exclusively* to electronics—with a broad background in designing specialized components such as electro-mechanical filters, transistors, and in using plated circuitry, modules and encapsulated components. Motorola—fully qualified to develop and produce the most complex electronic systems.

For more information, or a prospectus of complete qualifications and experience, write Motorola today.

The French Air Force CT 20 in the assembly area of the SNCA du Nord manufacturing plant. The CT 20 is one of the most advanced target missiles now in production in France.

French Missile Production

By Jean-Marie Riche

PARIS—Although the French authorities are very reluctant to discuss their progress in the missile field, the concentrated efforts of their aviation industry during the past ten years is beginning to pay off. Some of the hardware resulting from this work has now reached the production stage. And in one field—antitank weapons—the products are described as among the best existing in the world.

Some information has been released about the SS 10 and SS 11 antitank missiles. At the recent Salon de l'Aviation in LeBourget, the SS 10 was on display with two air-to-air weapons of SNCA du Nord and Matra which are now reaching the production stage. Some experimental vehicles were also shown, stressing French interest in other directions. The practical meaning of this research effort is not known.

French policy in the missile field was, however, outlined earlier this year by the present premier of France, then the defense minister, Bourges-Maunoury. The head of the French government was the first politician to warn the nation that it was entering the missile age. "The conclusion of the present research effort should be the production of an arsenal of defensive and retaliation weapon-systems without which French independence could not be guaranteed." The French are now at work on the development and construction of a surface-to-surface strategic missile (sol-sol strategique), with a range estimated between 1600 and 2000 nautical miles. This is a formidable challenge for industry. Production will require pooling of efforts by the major aviation and electronics manufacturers. This weapon, which may be armed with nuclear warheads, will help the current experimental work on surface-to-air and air-to-air missiles.

French manufacturers have asserted that missiles would be the ultimate result of experimental aircraft like the hybrid interceptor *Trident* of Sud-Aviation, *Leduc 022* and *Griffon* of Nord and like the *Flying Atar* VTO of SNECMA. The first *coleopter*, expected soon, and the *Trident* are equipped to fly by radio-control.

Although missile-minded, French industry is hampered by skimpy appropriations, only a small fraction of what it takes to produce a family of weapons like those in the U.S., the USSR or even Great Britain. More money is going for missile research, however. In 1955, of industry's total research grant, only 22.6 per cent went to missiles. In 1956, this was raised to 30 per cent and in 1957 to 31.6 per cent.

In view of the increased emphasis on missiles, the coming months will see the formation of groups with which aircraft research activities and electronics companies will associate themselves. In some cases, the aircraft companies will absorb research departments of electronics companies. These developments should give a boost to an effort which may have been somewhat delayed through the reluctance of the majority of the industry to

SS 10 (above left) and SS 11 (left) are surface-to-surface antitank, antiemplacement missiles powered by a solid rocket motor. Missiles are controlled by transmitting signals through two wires which unwind from a drum. The MATRA 510 (above) is an air-to-air missile powered by a two-stage solid rocket motor. Missile carrier is the TRIDENT.

abandon "classic" production items in favor of missiles.

In addition to aviation companies, work has been undertaken in the missiles field by DEFA and the Army Arsenal, which was responsible for the development of the surface-to-air *Parca* missile, whose production status is not clear. ONERA, the French counterpart for NACA, has also produced interesting test vehicles, some of which were on display at the Bourget exhibition.

Testing of French missiles takes place at the Colomb-Bechar range in South Algeria, a well-equipped interarm testing base at the fringe of the Sahara desert.

The SS 10 and SS 11 are surface-to-surface antitank and anti-emplacement weapons designed by SFECMAS, a company now operated by the Societe Nationale de Constructions Aeronautiques du Nord. Equipped with one solid rocket motor for acceleration and one for cruising, they are guided by two isolated electric wires which unwind from a drum. A small gyroscope, especially developed for the missile, is described as its best construction asset. Their warhead is provided with a hollow charge which can pierce armor plates 400-500 mm thick.

In production for about four years, the SS 10 is used as standard antitank equipment by several armies including the French and German. Recently demonstrated to experts of NATO, it has been recommended for general adoption by the NATO forces. The SS 10, whose operation is very simple (guidance by straight visual reference), can be used either as a surface-to-surface antitank or anti-emplacement weapon or, mounted on helicopters or light planes, as an air-to-surface weapon.

The SS 11, derived from the SS 10, is a smaller diameter missile, also guided by wire, but whose range is more than twice that of the SS 10. The velocity of the missile at the end of its cruise is twice that of SS 10. The warhead of the SS 11 is also heavier.

Nord 5103

This missile has been designed by SNCA du Nord for the armament of transsonic, subsonic or supersonic interceptors. It is characterized by its pointed warhead and its four cruciform wings which are sharply swept.

MATRA Type 510

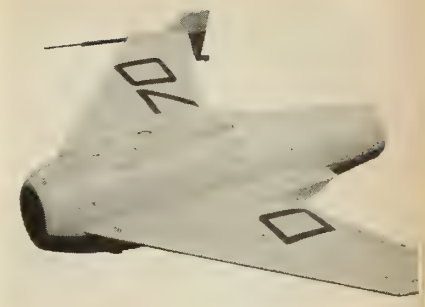
MATRA (Societe Generale de Mecanique-Aviation-Traction), a company closely connected with the Breguet Aircraft Co. has developed several air-to-air missiles from which the M510, now in production, was developed. The initial M04 test model was followed by the M20 model (range: 1 mile; Mach 1.5) which is produced for interceptors in the *Mystere IV* class.

MATRA developed the M051 missile for the *Vautour*. Equipped with beam guidance or homing head, this missile has a length of about 9'10", a weight of 350 lbs. and can reach a very high speed. Propulsion unit is a two-stage solid-propellant rocket motor. The MATRA 510, also of canard design, has a burnout velocity above Mach 2 and an optical homing head. It is part of the *Trident II* weapons system.

SE 4200

This surface-to-surface missile is still on the secret list. The warhead is mounted in a pod under the fuselage. Missile is launched by two boosters from platform.

Specific Data:



Manufacturer:	Sud-Aviation
Mission:	surface-to-surface
Range:	55-60 n. miles
Length:	10'
Span:	7' 1"
Launching Weight:	1400 lbs.
Velocity:	subsonic (Mach 0.9)
Guidance:	radio
Powerplant:	ramjet cruise plus two solid-propellant boosters (take-off)
Status:	in production

Target Missiles

CT 10—Manufactured by SNCA du Nord for about 10 years. Used by the French Air Force, the UK Royal Navy and the services of several other countries. Length: 35'. Velocity: 280 mph.

CT 20—A development of the CT 10, manufactured by SNCA du Nord. Has flight time of one hour. Velocity: Mach VO.9.

SE1502-1523-1524 — air - to - surface target missiles built by Sud-Aviation. ★

The majority of French missiles in production are of the aerodynamic cruise design with rocket boost and jet sustaining engines. Top to bottom—SE 4200, a subsonic ramjet surface-to-surface missile with a range of 60 miles. CT 10, a target missile that has been in production for about 10 years. Velocity 280 mph. CT 20 is a development of the CT 10. The CT 20 is also subsonic with a flight time of one hour. Both missiles are jet propelled with solid propellant rocket boost. CT 10 is similar in configuration to the early V-1. SE 1524 is an air-to-surface missile in limited production by Sud-Aviation.

20 YEARS OF PROGRESS

Bendix-Pacific

Pacific Division of Bendix Aviation Corporation has two decades of knowhow under its belt. During the first year of its existence Bendix-Pacific was proud to supply its equipment to three aircraft companies. Now, in 1957, Bendix-Pacific hydraulic, electronic or electro-mechanical components and systems are specified by all major U. S. aircraft companies and are in service on every modern airliner, on all different types of military planes and on the large majority of missiles and pilotless aircraft. Bendix-Pacific has earned this leadership through twenty years of progressing achievements. Its latest developments in advanced systems are proof of the diversity and flexibility of Bendix-Pacific engineering. The results can be measured in greater performance for you.

Propulsion Engineering

By Alfred J. Zaehringer

AMMONIA IS SAFE say German researchers. Explosive limits of NH_3-air mixtures are 16-27% while H_2-air is 9-66.3%. The ammonia explosion limits decrease with humidity and are of less force than hydrogen. Few ammonia combustive explosions have been encountered.

FREEZING POINT OF TETRANITROMETHANE can be depressed to −20 by use of an N_2O_4 additive. The nitrogen tetroxide, says an Italian patent, also makes for easier reaction with amines or liquid ammonia when TNA is used as a liquid-rocket propellant.

OXYGEN PLANT SAFETY has been outlined by Linde Co. in Munich. Two big factors in preventing explosions in separating plants are control of initiating conditions and elimination of explosive materials. Former method eliminates mechanical effects, sparks, isolated drying in crevices and removes reactive materials (radicals, ozone, etc.). Latter consists of eliminating hydrocarbons, COS, and H_2S. Acetylene is said to be the most dangerous troublemaker.

MORE AMMONIUM PERCHLORATE for solid propellants is in sight. One Norwegian electrochemical firm is trying to sell the high energy oxidant on the East Coast to Atlantic Research and Thiokol. U.S. capacity for AP, though, is still ample. The Norwegian AP could lead to lower prices thus stimulating use. Continuous nitration process for production of nitroglycerine and other propellant materials has been introduced in Sweden. Nitroglycerine Aktiebolaget (founded by Alfred Nobel in 1884) at Gytorp uses nitration by injection whereby products in nitration stages are removed as a nonexplosive emulsion. Thus, only a small amount of free NG is actually present in the process. The firm can eliminate conventional mounding and need only use a concrete wall to separate the nitrator and the control area. NG is a vital ingredient in modern double-base solid propellants.

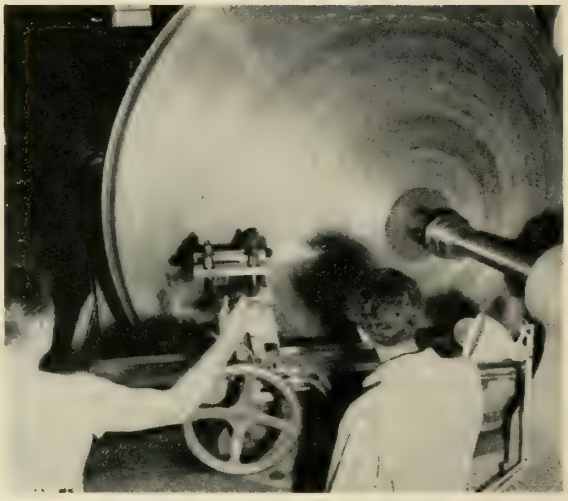
BORON FUELS IN BRITAIN: American Potash & Chemical has a subsidiary now going in the UK which may introduce exotic boron fuels and high energy lithium oxidants.

EXOTIC OXIDANTS ARE IN THE WORKS. In addition to studying liquid ozone, Soviets at Moscow State University have bombarded LOZ with atomic hydrogen at −196° C. A deep blue film, which solidifies, results. The solid, colored blue by the LOZ, decomposes violently with oxygen evolution and leaves behind a 30% water solution of hydrogen peroxide. The experiments, which are also underway at other facilities, are aimed at the synthesis of hydrogen superperoxide (H_2O_4). Another project is concerned with the deep thermal decomposition of methane.

AUTOMATIC CONTROLS FOR ROCKETS are being investigated by the Center de Recherches Hydrauliques et Electriques, Paris. Hydraulic servos are controlled by electrical inputs. Particular attention is devoted to synthetic fluids for high-temperature operation. Several models, ranging from 5-20 horsepower, have been built.

NUCLEAR PROPULSION FOR ROCKETS is being studied by the Swiss Oerlikon firm. A design study project has been reported underway.

WORKING FLUIDS FOR ROCKETS were studied intensively by Bremen engineers. At temperatures of 2500-3250°C and pressures of 16-64 atm, gamma is remarkably alike for the gases, hydrogen, water, nitrogen, air, oxygen, hydrogen chloride, and carbon dioxide. At a given temperature, the average molecular weight increases with pressure. With water as a working fluid (at 64 atm & 3250°C), a theoretical velocity of slightly over 12,000 ft/sec is obtained.

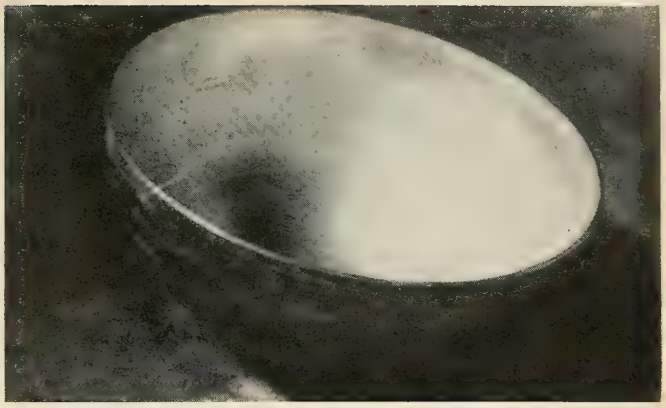


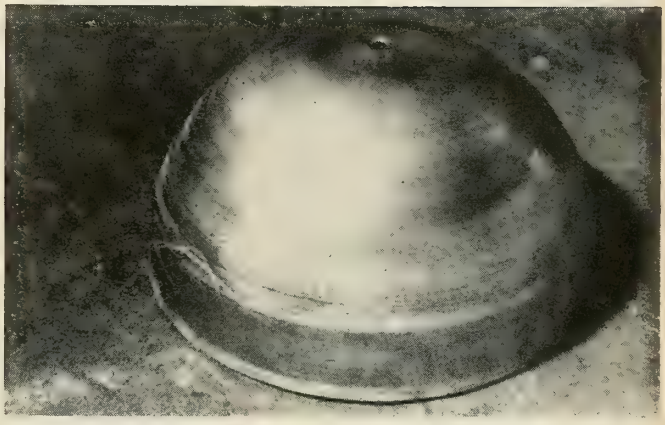
EVER HEAR OF A "FIREFLY HUNT"? We just heard that observers who will take part in visual tracking of the *Vanguard*-launched satellite may conduct such hunts. According to a bulletin put out for Moonwatchers, as they are called, the firefly often seriously detracts an observer looking through a tracking telescope. The bulletin said, "At least one Moonwatch group conducts a firefly hunt around the station before the observing session." The firefly's quick flash *could* be mistaken for a passing satellite.

METAL SPINNING

New Imported Equipment Spins Economy into Aircraft and Missile Parts

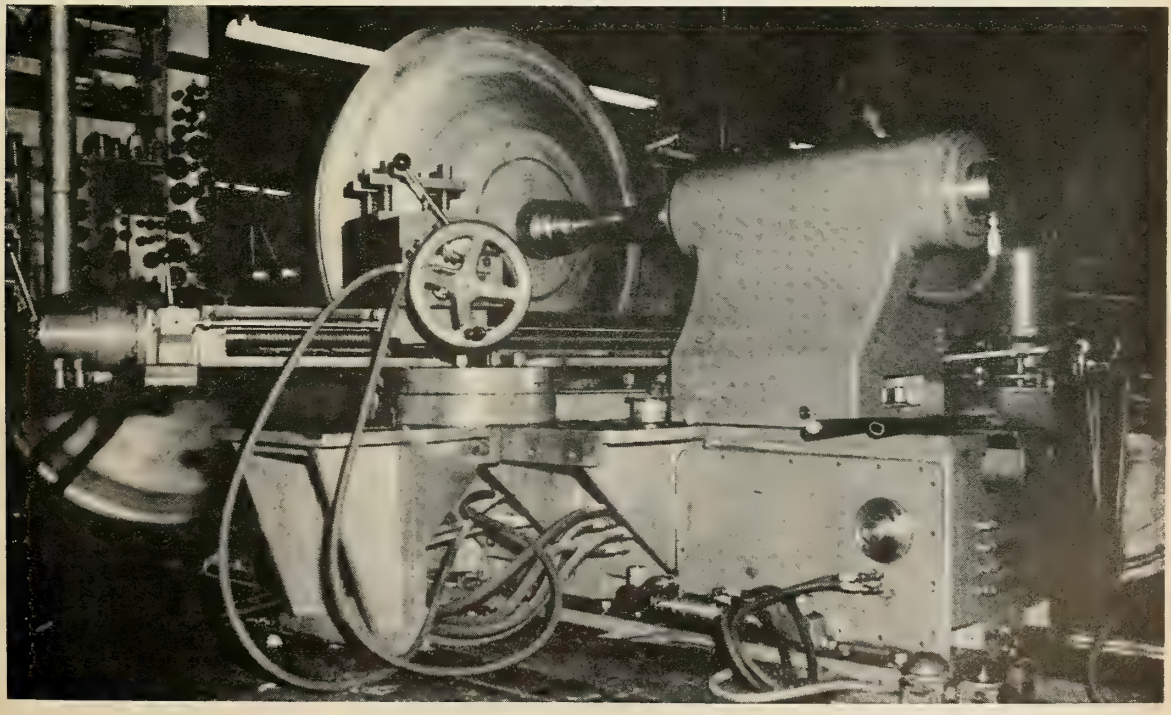
Welding operations are eliminated, weight is saved, unit cost reduced with new, imported machinery used to spin heavy or thick-walled aircraft and missile parts. Below, missile cylinder was spun "hot" on the lathe. Prior to metal spinning, manufacturers had been wrapping and welding the body, then welding on bottom. This cylinder was made from flat, round blank of ½" aluminum, 60" in diameter. Finished wall thickness is .380" with a 125 finish. Machines are from Germany.





Cold spinning ⅝" aluminum alloy to an 8' finished part for ICBM pressure bulkhead. Used here is Model Plb 1200 hydraulic spinning and planishing lathe. German manufacturers are Leifeld & Co.

Right, cone of ⅝" magnesium, hot spun in two parts on LEICO Model Plb 1200. Previous to new method, welded heavy or thick-walled parts caused warpage which in turn required an inside and out operation. The machines are now being used in many parts of U.S.A.



Titanium hemisphere 3/8" thick, hot spun on LEICO Model Plb 600 lathe. New process makes it possible to finish one symmetrical piece to the point where it is ready to use as it leaves the lathe. First complete metal spinning set up in this country was Hydro Metal Spinning Corporation's installation of five lathes and one hydraulic flow turning machine in Los Angeles, Calif.

Stainless steel 1/4" type 304 hot spun on LEICO Model Plb 600. Spinning diameters possible run from 52" to 130 1/4", available through various sizes of the fully hydraulic machines. They can produce 5/8" aluminum and magnesium, 3/8" titanium and 7/8" cold rolled stainless steel sheets.

Picture below shows a high efficiency metal spinning and planishing lathe, Model Plb 1200. This machine will cut the fabrication cost of aircraft and missile parts. The company's representative in the United States is Albert H. Wilhelm, 1020 W. 20th St., Los Angeles, Calif.

COLD FORMING in missile production

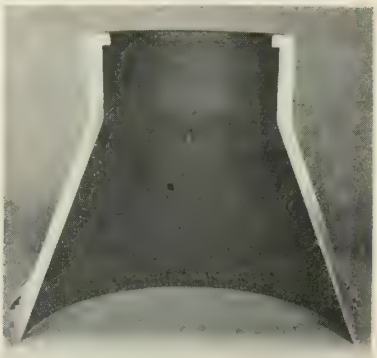
COLD FORMING processes originally developed by Norris-Thermador Corp. for the fabrication of cartridge cases are now beginning to be used to produce cheaper and better metal components for rockets and missiles.

One good example is the new-type body being made for Aerojet-General Corp.'s long-established JATO unit. Formerly welded together from four separate parts, the chamber for the 15KS-1000 is now being drawn in one single piece in the large capacity presses at Norris-Thermador's Vernon, Calif., plant.

This method of forming makes possible lighter weight and a substantial cost saving for Aerojet. With no welds, the chamber has improved reliability.

Norris-Thermador manufactures a wide variety of products ranging from bath tubs to electronics equipment. It makes all the automobile wheels for all cars assembled on the West coast. Its first ordnance contract—1000-pound practice bombs for the Navy—turned out to be an unprofitable venture, but provided the company with much valuable experience. On its second Navy contract—for $1-million worth of aluminum cartridge containers—Norris-Thermador, then known as Norris Stamping and Manufacturing Co., developed the ingenious methods and machinery to produce deep drawn seamless containers, an achievement considered impossible at that time.

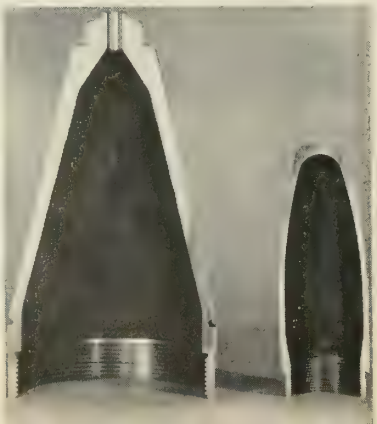
Evidence of the company's resourcefulness was demonstrated again when it solved one of the biggest production problems of World War II by developing low cost methods of producing satisfactory antiaircraft cartridge cases from steel instead of brass.



Not long ago, Norris-Thermador turned out its 55th million artillery-size cartridge case. But at the end of Korea, it found itself with 13 lines of shell cases and dwindling orders in this particular phase of its operations. That's when its government products department focused its sights on the rocket field. Subsequent production includes more than 2 million rocket motor tubes for the widely used 2.75-inch *Mighty Mouse*, produced by the cold drawn process.

Norris-Thermador makes both the JATO chamber and the aft cap for Aerojet's Navy JATO unit, each in one-piece operations. The chamber is cold formed with an integral spud section from an AISI 4130 steel blank. The aft cap is cold formed from a mild steel blank. Using this process, Norris-Thermador guarantees a minimum yield strength of 100,000 psi for the chamber side walls. Day-to-day values actually are 120,000 psi.

This company also has a subcontract from Phillips Petroleum Co. to produce main body and nozzle for the M15-A1 JATO for the Air Force, and a plant for this purpose was built last year in Waco, Tex. For this JATO unit, Norris-Thermador also manufactures the fixtures with which it is fastened to the aircraft. The Phillips-designed JATO, however, incorporates different design and therefore different manufacturing processes than the Aerojet.



Norris-Thermador's ability to draw

The rocket business is basically a low-cost business. As such, it enjoys the privilege of a greater variety of production processes. These pictures show the great number of different shapes that can be made by cold forming and cold extrusions. These are examples of Norris-Thermador's production.

and extrude items with varying wall thicknesses is attracting increased attention from rocket and missile designers. Its cold forming operations extend into the 4130 and 4140 alloy steels as well as in mild steels, aluminum, copper and brass.

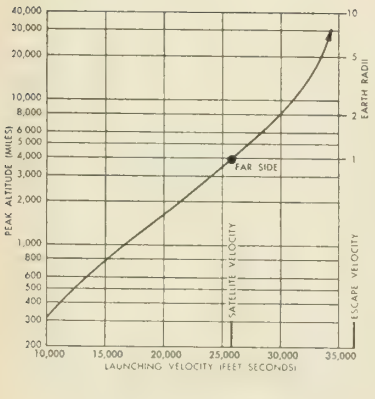
"We are just on the threshold of what can be done with metals," said Larry Shiller, chief research and development engineer.

One of Norris-Thermador's newer cold forming projects is for the body of the *Hawk* for Raytheon Manufacturing Co., which has the prime contract on this Army missile. To be built in two pieces of 4130 steel 95 inches long and 14 inches in diameter, with a girth weld, this is reported to be the longest cylindrical item ever formed by deep drawing.

So far, Norris-Thermador's applications have been to small and medium-size rockets or missiles. "But we are alert to the larger sizes," said Donald P. White, vice president of the company's government products division.

Norris-Thermador's Vernon plant is one of the largest and most comprehensive metal forming facilities in the West, with a press department housing mechanical presses ranging from 25 to 400 tons and heavy hydraulic presses ranging from 45 to 6000 tons capacity. Military work constitutes only a small part of Vernon production, but two other plants are devoted entirely to government products. These are the Riverbank Ordnance plant, a joint Army-Navy facility near Modesto, Calif., where Norris-Thermador operates at a very low rate—just enough to maintain an organization which can be rapidly expanded if an emergency should arise—and the JATO plant at Waco, Tex. ★

Parts that can be made by cold processing include nozzles, bulkheads, feed fitments, nose cones, casings, entire motors (in the case of small ones), etc. Directly to left are motor bodies extruded and deep drawn from an AISI 1030 steel slug. Below are cold-worked nozzle plates from AISI heat treated steel.



Project Far Side

Man's first stride into space uses off-the-shelf hardware

By Prof. S. F. Singer

Physics Department
University of Maryland

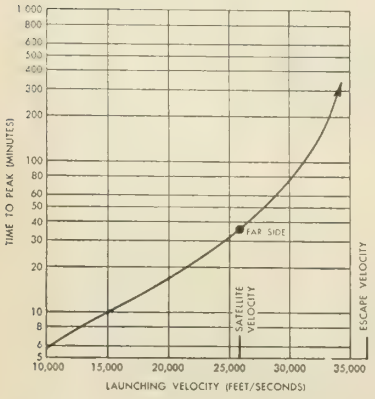


Figure 1. Parameters of FAR SIDE concept.

A NEW DIMENSION has been added to high altitude research: *Far Side,* which will explore space out to one earth radius (4000 miles) and possibly higher. Conceived by scientists of the Air Force Office of Scientific Research and developed by Aeronutronic Systems, Inc., the *Far Side* vehicle is a low-cost solution for reaching the highest altitudes yet attained by man. It is a multistage rocket launched at high altitude to overcome the atmospheric drag; specifically it is a four-stage combination of ten solid rocket motors lifted by a Skyhook balloon to an altitude of over 100,000 feet (m/r August 1957, p. 45).

The 1900-pound vehicle carries only a three-and-a-half-pound payload, but thanks to instrument miniaturization this tiny package buys a lot of scientific research.

High Altitude Vehicles

Because of its extreme altitude capability *Far Side* operates in a class quite different from that of other research rockets such as the *Aerobee, V-2, Viking,* or *Dan* (m/r March 1957). It is designed specifically to explore the exosphere region above the ionosphere, sometimes called the outer ionosphere. This is the region above 250 miles where collisions between atoms become so rare that we can truly speak of it as the boundary of space. While other research rockets investigate the properties of the lower atmosphere and ionosphere, the *Far Side* vehicle studies the nature of the space around the earth, eventually as far as the moon and beyond.

It opens up the possibility of discovering radically new scientific phenomena present in interplanetary space. In a sense these investigations supplement the research to be carried out in the first earth satellites: whereas the earth satellite explores for long periods of time at about 300 miles altitude relatively close to the earth, the *Far Side* vehicle thrusts vertically out into space over ten times as high. It can reach regions which are not accessible to the satellite, but it does not have the long satellite lifetime.

Team Behind Far Side

Project *Far Side* represents the fruitful collaboration of two highly qualified organizations. The Air Force Office of Scientific Research has been working on space problems for some time by supporting research on cosmic rays, plasma physics and interplanetary exploration by means of radio "whistlers."*

This support of basic science according to AFOSR commander Brig. Gen. H. F. Gregory is in accord with the mission of AFOSR "to undertake

** low frequency radio waves produced by lightning discharges and guided along magnetic force lines to the opposite hemisphere (Fig. 8.)*

Fig. 2. Propulsion Study for Escape Vehicle

In this study the same criteria are used as in the *Far Side* design:

1) A four-stage rocket launched from a balloon to obtain maximum effectiveness. (Compare this with a two-stage approach by Kurt Stehling in m/r October 1956.)

2) Solid-propellant motors are used because of greater simplicity and lower cost in the size range considered here.

3) The stages are designed with optimum matching to give the best overall performance in terms of highest velocity with minimum all-up weight.

The following assumptions are made with regard to the propulsion system:

1) The maximum velocity obtainable depends on the maximum weight balloon can carry and the minimum useful weight for the payload. We assume here a 3000-pound maximum balloon load and a payload weight of two-and-a-half pounds.

2) Solid propulsion units are used in this design which have a vacuum specific impulse of 250 seconds and a mass ratio of 0.86.

	STAGE			
	#1	#2	#3	#4
Initial Wt.	2500	416	69.5	11.5
Final Wt.	350	58	9.7	1.6
Propellant Wt.	2150	358	59.8	9.9
Total Wt.*	3000	500	83.5	14.0
Effec. Mass Ratio		0.72		
Velocity increase per stage		10,200 ft./sec.		

*Incl. weight of following stages and payload.

The final velocity is 40,800 feet per second. This exceeds the escape velocity from the earth, which is 36,000 feet per second near sea level.

This vehicle could therefore escape entirely or attain extremely high altitudes if deflected and returned to the earth by interaction with the moon's gravitational field (Fig. 2).

exploratory and pioneering research to maintain the USAF's dominant technical position," (m/r July 1957, p. 105).

The AFOSR attitude toward space research has also been forcefully stated by Col. William O. Davis, deputy commander, operations, (m/r June 1957), who pointed out that "the space around the earth is becoming our next military environment; there is an intrinsic necessity that we understand this new environment."

Dr. Morton Alperin, who heads the Directorate of Advanced Studies of OSR in Pasadena, Calif., has been laying the groundwork for space research by supporting research on advanced solid propellants of high specific impulse and research on unique and exotic propulsion systems based on magnetohydrodynamic principles.

It was under his guidance that Project *Far Side* was first outlined and put together. The industrial prime contractor, Aeronutronic Systems, Inc., seemed a natural to carry out the development and build and launch the vehicle. Vice president Ernst H. Krause initiated the upper-atmosphere rocket-research program at NRL at the end of World War II.

Its other key scientists are also well known in the upper-atmosphere and cosmic-ray field—men like Montgomery H. Johnson, Ralph J. Havens and Ernest Martinelli. Project manager is Herbert L. Karsch, formerly the technical director of the White Sands Proving Ground, where he was responsible for the early V-2 program and

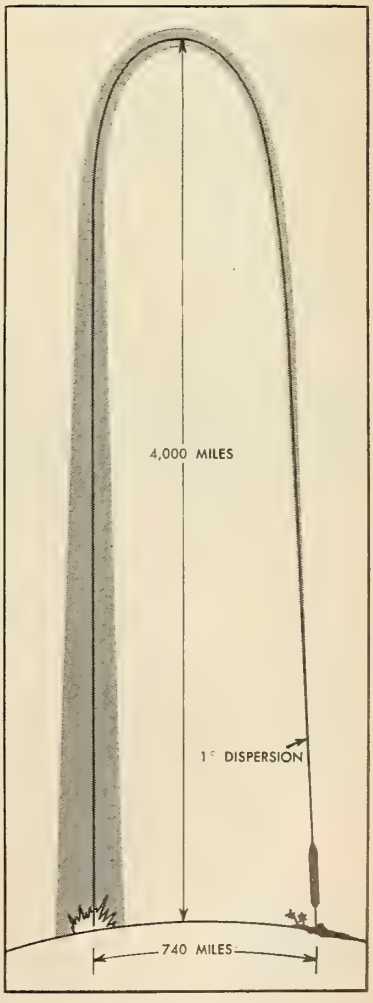

Figure 3. Trajectory of 4000-mile FAR SIDE rocket.

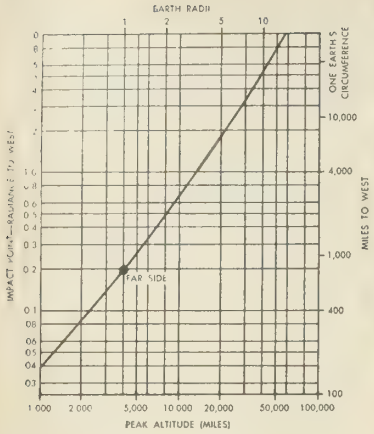

Fig. 4. Relationship of a altitude to impact point.

other rocket programs. In charge of the electronics portion of the *Far Side* program is Harrison Smith, Jr., formerly head of the NRL telemetering program.

Technical Aspects

Together with General Mills' technical staff, these men worked out a unique launching scheme for the 23-foot long, four-stage rocket vehicle. For the critical release phase on the ground they designed a mobile launch truck. Other knotty problems had to be solved: stability during firing, stage separation with minimum dispersion, and intense aerodynamic heating with a maximum velocity of nearly 18,000 miles per hour.

RESEARCH GOALS

Fig. 5. Nature of Outer Ionosphere (controlled mainly by earth's gravitational field and solar radiation).

What is the concentration of atoms at different altitude levels? What is the composition? Where does hydrogen take over? What fraction of atoms is ionized? What are the electrical properties? How rapidly does the temperature rise? How fast does the atmosphere evaporate into space? How far up does the gas rotate with the earth? What "winds" exist?

Bristol's Syncroverter Switch. *Covered by patents.*

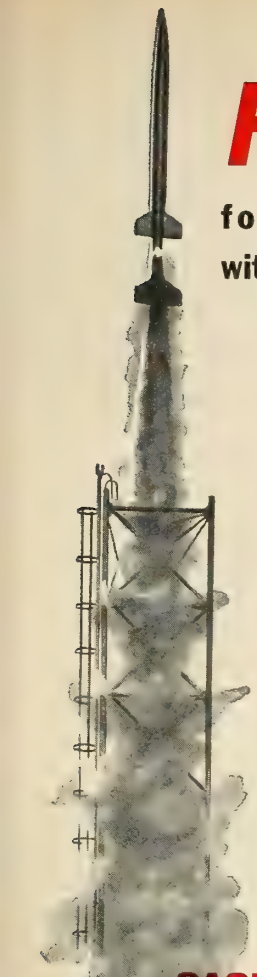
Need a high-performance miniature chopper?

Bristol's® Syncroverter Switch is the ideal dc-to-ac signal voltage converter for low-level applications in servo systems, computers, telemetering systems, communications and navigation equipment, and in many other types of electronic equipment.

LONG LIFE and IMMUNITY TO SEVERE SHOCK and VIBRATION are outstanding characteristics of the Syncroverter® Chopper. During vibration over the range of 5 cps to 500 cps and up to 30G, the effect on output waveform is negligible. Operation is within normal tolerances after five 30G impacts in each of the six major directions. Write for more complete specifications. The Bristol Company, 173 Bristol Road, Waterbury 20, Connecticut.

TYPICAL OPERATION

Driving frequency range:	0-2000 cps (400 cps used for these characteristics)
Coil voltage:	6.3V sine, square, pulse wave
Coil resistance:	85 ohms
***Phase lag:**	55° ± 10°
***Dissymmetry:**	Less than 4%
***Switching time:**	15° ± 5°
Temperature:	—55°C to 100°C
Operating position:	Any
Mounting:	Flange or plug-in—fits 7-pin miniature socket



*These characteristics based on sine-wave excitation.

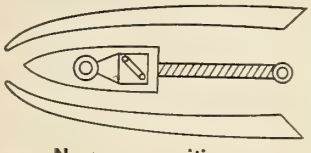
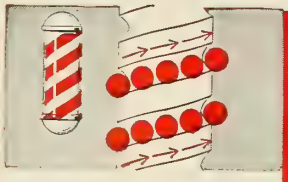
FAIL-SAFE ACTUATION

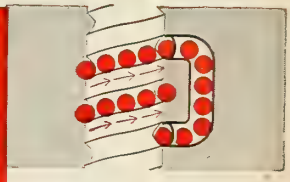


for guidance and control in difficult environments with SAGINAW b/b SCREWS and b/b SPLINES

TYPICAL APPLICATIONS



Control surface actuators



Nose cone positioners

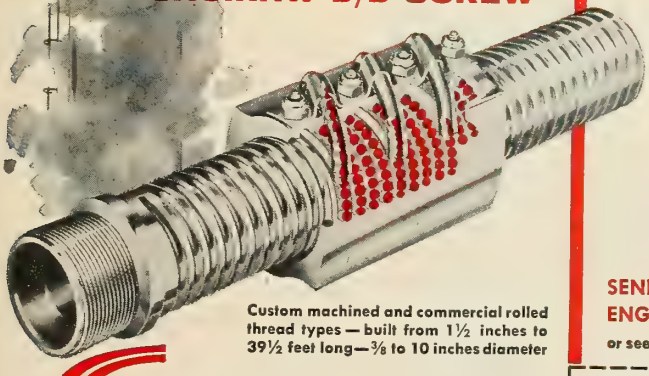
Evelon positioners • Afterburner controls • Speed brake actuators • Rocket engine displacement actuators • Clamping mechanisms for missile boosters • Fuel controls (3-dimensional cams) • Black box tuning devices—telemetering and guidance systems • Antenna coupler tuning mechanisms

Nut *glides* on steel balls. Like stripes on a barber pole, the balls travel toward end of nut through spiral "tunnel" formed by concave threads in both screw and mating nut.

At end of trip, one or more tubular guides lead balls diagonally back across outside of nut to starting point, forming closed circuit through which balls recirculate.

1 VITAL POWER SAVINGS. With guaranteed efficiency of 90%, Saginaw b/b Screws are up to 5 times as efficient as Acme screws, require only ⅕ as much torque. This permits much smaller motors with far less drain on the electrical system. Circuitry is greatly simplified.

2 SPACE/WEIGHT REDUCTION. Saginaw b/b Screws permit use of smaller motors and gear boxes; eliminate pumps, accumulators and piping required by hydraulics. In addition, Saginaw b/b Screws themselves are smaller and lighter. Units have been engineered from 1½ in. to 39½ ft. in length.

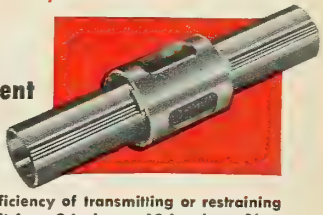


3 PRECISE POSITIONING. Machine-ground Saginaw b/b Screws offer a great advantage over hydraulics or pneumatics because a component can be positioned at a predetermined point with precision. Tolerances on position are held within .0006 in./ft. of travel.

4 TEMPERATURE TOLERANCE. Normal operating range is from −75° to +275° F., but assemblies have been designed in selected materials which function efficiently as high as +900° F. These units are practical where hydraulic fluids have lost efficiency or reached their flash point.

5 LUBRICATION LATITUDE. Even if lubrication fails or cannot originally be provided because of extreme temperatures or other problems, Saginaw b/b Screws will still operate with remarkable efficiency. Saginaw units have been designed, built and qualified for operation without any lubrication.

6 FAIL-SAFE PERFORMANCE. Far less vulnerable than hydraulics. In addition, Saginaw offers three significant advantages over other makes: (1) Gothic arch grooves eliminate dirt sensitivity, increase ball life; (2) yoke deflectors and (3) multiple circuits provide added assurance against operating failure.



SAGINAW b/b SCREW

Custom machined and commercial rolled thread types — built from 1½ inches to 39½ feet long—⅜ to 10 inches diameter

SAGINAW b/b SPLINE

Averages 40 times lower friction coefficient than sliding splines

Radically increases efficiency of transmitting or restraining high torque loads; built from 3 inches to 10 feet long, ⅜ to 6 inches diameter

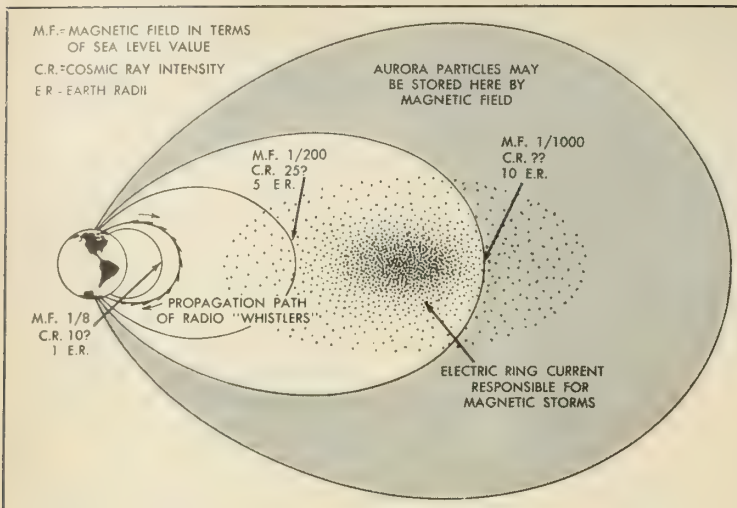

Fig. 6. Radiations in the Outer Ionosphere (controlled mainly by earth's magnetic field)

How rapidly does the magnetic field fall off? Does the ring current exist? How does the cosmic ray intensity increase. What is its value in free space? Where are the auroral particles stored? How are they accelerated before bombarding the ionosphere? Does the space intensity of meteoric dust increase with altitude?

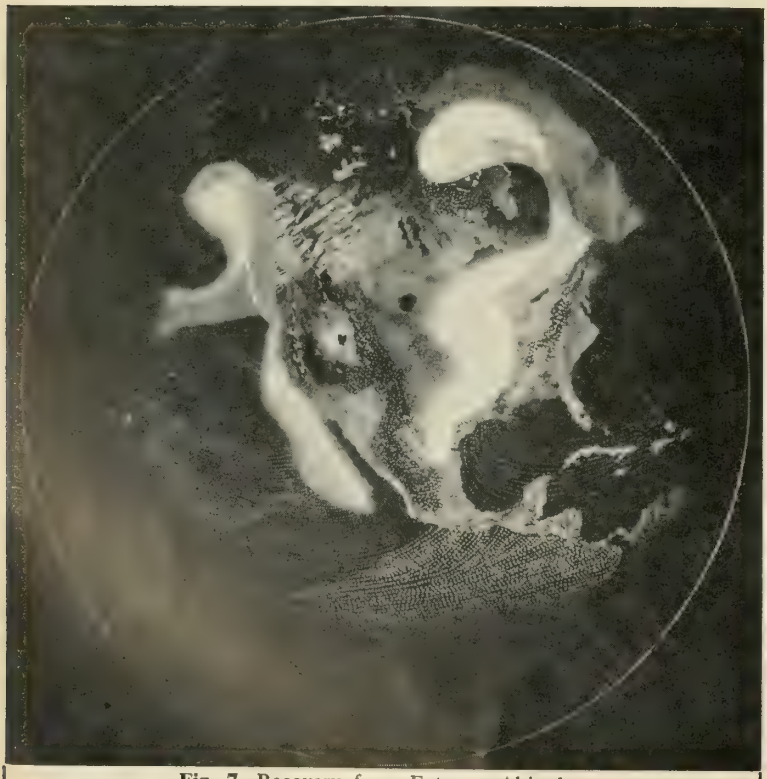

Fig. 7. Recovery from Extreme Altitudes.

Photographic film; high-altitude pictures for weather studies. Cosmic ray emulsions; heavy primary particles; biological specimens (bees, fruit-flies); prolonged exposure to outer space radiation—all will aid science.

because of the excellence of its solid propellant motors. Thiokol's *Recruit* motor is a new achievement in efficiency, mass ratio and specific impulse, while Grand Central's *Arrow* motor duplicates the performance of its bigger brother but on a smaller scale.

The staging design follows a simple optimization principle. One can, to a first approximation, neglect atmospheric drag since the launching takes place above 98 per cent of the atmosphere.* The carrying capability of the launch balloon sets an upper limit to the vehicle weight. With an assumed four-pound payload, optimum performance of a four-stage design demands that each stage represent an increase of impulse by about a factor four. Thus, we achieve the *Far Side* vehicle design.

Since the mass ratio and the specific impulse for each stage are about the same, the velocity increments produced by each stage are about equal. In order to reach a final velocity of five miles per second (which incidentally is also the satellite velocity), a velocity increment of one-and-a-quarter miles per second is required for each stage.

If one deviates from this optimization principle, for instance, by making the velocity increments unequal, the whole combination loses in efficiency and the all-up weight must be greater.

As currently designed, the *Far Side* vehicle represents the most efficient combination of existing high performance rocket motors. By the same token, the *Far Side* vehicle also constitutes the cheapest solution for reaching extreme altitudes. As the performance of solid motors improves, higher velocities, and therefore much higher altitudes, become possible. The *Far Side* design philosophy is illustrated in the table of Fig. 1, which shows that an escape vehicle or moon rocket is easily achieved with motors having a (vacuum) specific impulse of only 250 seconds and a mass ratio of 0.86.

Dynamics and Trajectories

With vehicles reaching such extreme altitudes, the radius of the earth itself (4000 miles) becomes the unit of measurement. Even the word "altitude" loses significance and is replaced by "distance from the earth."

Increasing the altitude beyond one earth radius is not very difficult: only a small increase in velocity is necessary. This can be seen in Fig. 1, or

** Because it will be launched at high altitude, rocket motors can be designed for operation in near vacuum, which increases their specific thrust by approximately 15 per cent.*

by considering that at the peak the initial kinetic energy of the vehicle $\frac{1}{2}MV^2_{init}$ must all be given up to the potential energy of the gravitational field; i.e. at the peak of trajectory the body has zero velocity and therefore no kinetic energy, but it has a large potential energy because it has been lifted so high up against gravity.

By setting the two energy expressions equal, one can derive the peak altitude very simply in terms of an initial velocity.* It is interesting to note that with an initial velocity equal to the satellite velocity, about 5 miles per second, the vehicle will go up exactly one earth radius. If one were to direct the *Far Side* vehicle horizontally, it would become an artificial earth satellite.

It is seen also from Fig. 1 that an increase in velocity of only 40 per cent, up to seven miles per second will give the vehicle enough kinetic energy to overcome the earth's gravitational field altogether. It now escapes from the earth and never comes back, unless it encounters the moon and becomes redirected as indicated schematically in Fig. 2.

By arranging this "collision" with the moon's gravitational field in a suitable way, one can make the vehicle travel around the far side of the moon and return it near the earth, where it can relay what it has seen by means of radiotelemetry.

To those used to measuring rocket flight times in terms of minutes, the length of time the *Far Side* vehicle spends above the atmosphere may come as a surprise. The initial series of vehicles, which goes to 4000 miles, takes 1960 seconds to reach peak altitude, and therefore spends over an hour above the earth's appreciable atmosphere. Fig. 1 shows the relation between the initial velocity and time to peak ascent.

The high altitudes and long periods of flight affect the location of the vehicle's impact point. Normally a high-altitude rocket lands pretty close to its launching point. We are not concerned with effects of the earth's rotation since the dispersion due to inaccuracies in the thrust and aerodynamic influences is ordinarily much larger. For extremely high altitudes, however, the rotation of the earth becomes of major importance.

If the vehicle is launched at the equator, in addition to its initial velocity derived from the rockets, it also carries a tangential velocity of 0.3 miles per second due to the earth's rotation.

Seen by a distant observer, the vehicle describes a portion of an ellipse, a ballistic trajectory which intersects the earth. It takes the vehicle considerable time to describe its trajectory; in the meantime the earth, and therefore the launching point, will have rotated. Knowing the flight time, we can calculate how far the launcher has turned and determine the impact relative to the launcher.

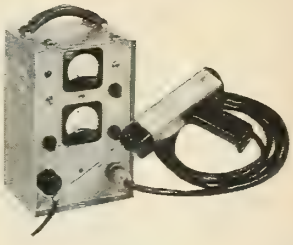
The results of such a calculation are shown in Fig. 3: a vehicle which has been launched at the equator with an upward velocity of five miles per second, equivalent to the velocity of the *Far Side* vehicle, will impact 740 miles west of the launch point. We also show the impact dispersion in the presence of an assumed one-degree dispersion in the launching angle.

For much higher altitude vehicles the flight time runs many hours. We can, therefore, have the vehicle impact to the east of the launcher. For example, for an altitude of 10 earth radii the vehicle would impact close to the launcher (Fig. 4).

This large dispersion of the impact point is only one of the problems peculiar to these extreme-altitude vehicles. This particular problem can be overcome by launching the vehicle near the pole where the effects of the earth's rotation are negligible.

But the problem of radio communication still remains. The signal power decreases as the inverse square of the distance, so that at an altitude of 4000 miles the power received is only one per cent of that from 400 miles.

Since it is generally not feasible nor economical to increase the transmitter power beyond a certain limit, this drawback can be overcome in one of two ways: the sensitive area of the receiving antenna can be considerably increased to collect more power from the transmitter, or the amount of information transmitted can be reduced and, therefore, the bandwidth of the transmitter as well as that of the receiver. This cuts down noise in receiving circuits.



Scientific Applications

Because of its unique high altitude capabilities, *Far Side* explores for the first time the virtually unknown regions surrounding the earth, sometimes called the outer ionsphere, which reach from the exosphere, 250 miles up, out to about 40,000 miles. We generally consider the region beyond this limit as interplanetary space. But within about 10 earth radii, both the earth's gravitational field and the earth's magnetic

field are strong enough to control what goes on.

The Outer Ionosphere

We know now from measurements with radio whistlers and from measurements of the zodiacal light that this region of the earth is not a vacuum but contains 600-1000 electrons per cc, and the same number of positive ions, mostly protons. In addition, we may have a large admixture of neutral atoms, but until now we have had no means of measuring their concentration.

The measurement of atmospheric density above satellite altitudes is probably the most important contribution of the *Far Side* vehicle. We suspect that there is an inner region in this outer ionosphere where hydrogen is still a minor constituent, but that beyond this inner region hydrogen, because it is the lightest atom, will begin to predominate.

It would be of the greatest importance to find out what percentage of the gas is hydrogen at various altitudes, and what percentage of the gas is ionized so that we can evaluate the degree of ionization, the electric conductivity and the radio propagation properties of the outer ionosphere. Temperature of the gas and winds are of great interest and can be measured by the *Far Side* vehicle.

Earth's Magnetic Field

While the earth's gravitational field is the main controlling factor in this outer ionosphere of the earth, the earth's magnetic field is important because of its influence on the motion of charged particles, many of which come from the sun. First of all, one would want to measure the magnetic field itself to see if it falls off as the inverse cube of the distance.

It is hypothesized that there is an electric ring current flowing around the earth, with its maximum located in the equatorial plane at about seven earth radii (Fig. 6). The current would produce its own magnetic field, which is superimposed on the earth's field. One should perceive, therefore, a different dependence of the magnetic field with distance than is ordinarily calculated.

This ring current is thought to be responsible for the magnetic storms which are observed on the earth during periods of high solar activity. Magnetic storms give rise to radio communication disturbances so that their study is of considerable military and economic importance. Now for the first time, a direct examination of the causes of magnetic storms may be possible.

Cosmic Rays

The earth's magnetic field also greatly affects incoming charged particles. The highest energy particles are the cosmic rays and they are deflected by the earth's field so as to follow very complicated trajectories before they finally reach the earth.

At the equator, however, all except the highest energy particles are turned away by the magnetic field. Therefore, as we go out from the top of the atmosphere at the equator, we see an increase in cosmic ray intensity (Fig. 6). As the magnetic field becomes weaker with increasing altitude, it begins to admit the lower energy cosmic rays. In this way we can measure cosmic ray intensity as a function of altitude and ascertain the number of low-energy cosmic rays as compared to those of high energy, and therefore the energy spectrum of cosmic rays.

A particularly interesting question relates to the presence of very-low-energy cosmic rays. They are normally not observed near the earth although they could come in near the poles, where the magnetic lines of force are vertical and offer no resistance.

If these low energy cosmic rays exist in interplanetary space, we should observe an increase in cosmic ray intensity beyond three or four earth radii.

Circle No. 58 on Subscriber Service Card.

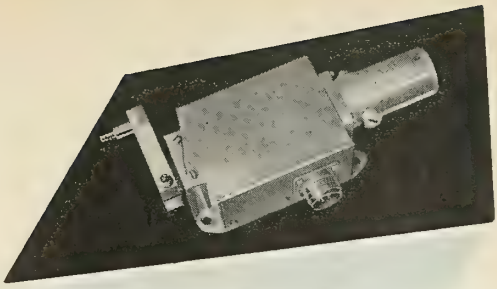
However, if they are absent, the intensity will flatten beyond that altitude, as shown in Fig. 6.

The *Far Side* experiments could settle this important question. In addition they would give data on the space intensity of cosmic rays, one of the important quantities for space flights.

Auroral Particles

Apart from the cosmic rays, the earth's magnetic field has even greater control over the auroral particles, probably high speed protons, which enter the upper atmosphere near the poles to produce the luminous aurora. The *Far Side* vehicle would be able to establish what region of space these particles occupy and could explore this region by shooting through it.

Very likely magnetic lines of force confine the particles to a narrow band in the auroral zone; but if one goes high enough, one should run into the auroral particles even at the equator Fig. 6).

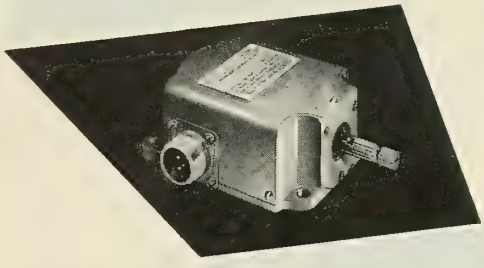


Such measurements would be of tremendous importance for geophysical theories. One of the outstanding problems is how these particles acquire the necessary high energy to penetrate so deeply into the atmosphere. Probably some kind of acceleration mechanism operates close to the earth, but its exact nature has not yet been determined.

Interplanetary Dust

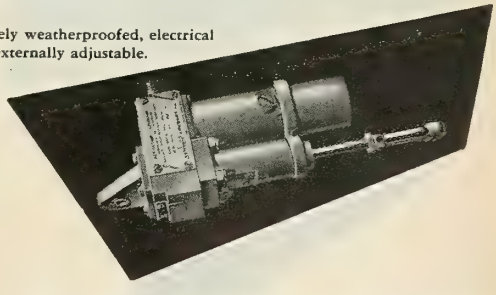
It may even be possible to check the influence of the earth's magnetic field on larger particles, e.g., interplanetary dust. Current theoretical ideas predict that dust particles will be highly charged by the photoelectric effect of the sun's ultraviolet radiation. In that case, the earth's magnetic field should act on dust particles in the same way as on cosmic rays. One should, therefore, observe an increase in the number of dust particles as one ascends at the equator to higher and higher altitudes similar to that shown in Fig. 6.

Significance of Experiments



Aside from their scientific interest, such measurements as will be possible through *Far Side* are important because they give us some firm figures on the properties of interplanetary space and on the intensity of various radiations in the vicinity of the earth. For example, even though the outer ionosphere can to a first approximation be described as a vacuum, the small amount of ionized gas present there may be of considerable concern to vehicles which navigate this region since it affects radio propagation. Furthermore, the electric charge of a vehicle is controlled by the electron density in its vicinity.

The rotary actuator above incorporates an electrically operated clutch which will permit either free rotation of the crank, or will engage the motor and gear train to drive the crank.



A built-in damper of the newly adapted eddy current principle resists input forces in proportion to input speeds when the crank is de-clutched and free to rotate.

This unique damper is also used in the magnetic brake below. The input shaft becomes locked to resist torque up to 200 inch-pounds when the brake is electrically de-energized. When the brake is energized, the input shaft is unlocked and the damper controls the input forces.

The linear actuator below, was designed and built to provide reliable electrical actuation in an environment of violent centrifuging and vibration. This unit weighs *less* than *1.5 pounds*, yet is capable of operating against opposing loads of *over 100 times* its own weight.

Although this actuator is completely weatherproofed, electrical and mechanical travel limits are externally adjustable.

Lyndon's ability to innovate — *to overcome routine engineering habits — results in the development of products which more precisely fit the requirements of your application.*

If you are in aircraft or missile design stages requiring electrical, pneumatic or hydraulic controls and systems, Lyndon is ready to help you.

4 FASTAIR CAMERAS RECORD ROCKET SLED TEST...

LOCATION OF 4 FASTAIR CAMERAS ON SLED
Photo Courtesy Coleman Engineering Company, Inc.

PICTURE QUALITY UNEXCELLED UNDER EXTREMELY ADVERSE CONDITIONS

Despite the high acceleration, vibration and extreme G load of rocket sled test FASTAIR High-speed Missile Cameras recorded pictures of highest quality. Small, sturdy and compact, the FASTAIR, the first camera developed specifically for missile and rocket studies, is *unexcelled.* The FASTAIR can also be used in other fields requiring the recording of action for analyses. Speed ranges from 12 to 600 pictures per second.

Robert W. Drury reports the FASTAX *camera is a credit to the photo equipment industry . . . never had a failure of any part of the camera or the very well thought out Camera Control unit. The new* FASTAIR *camera has proven to be an outstanding missile-borne camera, well designed for the job.*

Long Time Exposures

Another unique advantage of the *Far Side* vehicle over ordinary rockets is the long time spent above the atmosphere. In this respect it resembles the earth satellite and, in fact, its applications are similar, e.g., the *Far Side* vehicle can be used to observe the solar ultraviolet and X-rays for time periods in the order of hours. Should unusual conditions such as solar flares develop during the flights, this information will, of course, be detected by the instruments and telemetered to the ground.

Flight-time is also important for certain equipment which requires long exposure, such as cosmic ray emulsions used to detect the small flux of heavy nuclei in the primary cosmic radiation. Balloons have the disadvantage of operating within the atmosphere, but an emulsion carried in the *Far Side* vehicle will receive a long exposure in free space.

Recovery

Cosmic ray emulsions must, of course, be recovered; so must many other small scientific payloads exposed at these extreme altitudes.

Of great interest to space-medical research are exposures of small organisms, such as fruit flies or seeds, to the intense cosmic radiation which exists at these high altitudes and to any of the other radiations present. Until now no exposures have simulated exactly the high-intensity flux of heavy cosmic-ray primaries which exists in outer space.

The prospects of designing a reentry body for the *Far Side* vehicle look very promising, in spite of the small payload allowed. The reason is that the important scientific questions of just what happens when a high-speed body re-enters the atmosphere have now been solved in connection with ICBM programs, and special materials, possessing desirable characteristics at high temperatures, are now perfected.

Recovery of scientific payloads, entering from a 4000-mile altitude with satellite velocity, will undoubtedly be one of the great pioneering achievements of aerophysics technology. It will provide proof of the important scientific applications which can be derived from the current research in the military missiles field. More than that, the successful demonstration of extreme altitude recovery will open the way to more ambitious projects in the recovery of larger payloads, until eventually a manned vehicle is successfully re-entered into the atmosphere.

In more than one sense, therefore, Project *Far Side* is our first thrust into space and an important step in the development of America's spaceflight program. ★

Terriers are launched from the Navy's guided-missile ship, U.S.S. *Boston*. In flight, Terrier homes unerringly on target. Missile is providing Navy with up-to-date air defense against attack.

AIR FLASK FOR A TERRIER

For the "Terrier"—the Navy's surface-to-air guided missile—ALCO produces the critical air flask which supplies pressure to guide the missile's flight-control surfaces. With this aid, the Terrier tracks and kills no matter what evasive action is taken. ALCO also builds Jato shells for the Army's "Honest John," and rocket boosters for the Air Force "Snark."

ALCO's success in missile components is drawn in large part from its broad experience in defense production—over $700 million in the past five years alone. Metal-fabricating skill from over 100 years' experience, and thermal and mechanical know-how that have made ALCO a leader in power products, also play key roles in the company's missile production.

ALCO can help in your missile program with this broad experience and with its extensive manufacturing facilities. We'd like to send you a copy of our brochure, "What Does it Take to Make a Missile?" which outlines ALCO's qualifications fully. Write Defense Products, Dept. DNM-1, P.O. Box 1065, Schenectady 1, N. Y.

HOW CALIDYNE CAN HELP PROTECT YOUR VIBRATION TEST INVESTMENT

CALIDYNE SYSTEMS ARE CUSTOM BUILT

For years, Calidyne has been building Vibration Test Systems to meet specific military, aircraft, automotive and industrial requirements. Most Systems have been custom-constructed for special applications. Although they were representative of the most modern equipment available at the time, it may now be to your advantage to modernize to meet the newer requirements of this fast-moving field.

HOW TO OUTWIT OBSOLESCENCE

Some of the older Calidyne Vibration Test Systems may have become obsolete to a point where they cannot be revamped to meet more modern requirements. With others, it is possible for us to up-grade the equipment so that its performance will compare favorably with any now being offered. In many cases this can be done without serious sacrifice of the original investment.

IT MAY PAY TO INVESTIGATE

When you want to investigate the possibility of bringing your Calidyne Vibration Test System up to date, get in touch with us here at Calidyne — we can quickly tell you what can be done. The telephone number is Winchester (Boston) 6-3810, or write:

industry briefs

Breakthrough on *Titan* Scored by Avco

A major theoretical breakthrough on the *Titan* ICBM nose cone has been scored at the Avco research laboratory. The company, which has a contract for the missile's nose cone totalling more than $111 million, has used shock tube experiments and X-17 flight tests for the principal sources of such data.

Security restrictions have prevented disclosure of the exact nature of the breakthrough, but it is known that the problem of heat transfer to the nose cone itself is understood and that the laboratory has constructed prototypes of the nose cone for *Titan* embodying these new concepts. They have the shape now considered feasible for the ballistic missile.

Waste King Organizes New Technical Division

Waste King Corp. has announced consolidation of three manufacturing operations and its advanced engineering and development arm into a new Technical Products Division.

The new division will develop and manufacture mechanical components and assemblies for guided missiles, precision machining of experimental missile and rocket parts and production of complex systems assemblies.

Garrett Builds Missile Valves

Phoenix, Ariz.—Garrett Corp.'s AiResearch Mfg. Co. has opened a new controls building for full scale production of controls for gases and liquids. The plant has about 500 employes working on valves for *Atlas*, *Titan*, *Thor*, *Regulus* and *Bomarc*. Some controls produced are designed for operation at temperatures up to 1000°F near absolute zero.

The completely refrigerated plant is of concrete block and its 40,000 square feet of floor space increase the company's Arizona division to over half a million square feet.

Navy SPR Drone Successfully Tested

The Navy's rocket-powered target drone, the XKDT-1, has been successfully flight-tested at the Naval Air Missile Test Center at Point Mugu. The missile-shaped drone is intended to sharpen the eye of Navy fighter pilots and operates near the speed of sound at altitudes up to 50,000 feet.

PYLE *star-line*® CONNECTORS

Assure long-lasting protection of vital connections under a wide range of extreme environmental conditions

Currently establishing itself as a performance leader in the missile systems field, Pyle-Star-Line connectors offer engineers an entirely new line of electrical connectors for universal military and industrial use.

With characteristics of construction and performance never before combined in compact, rugged, lightweight standardized connectors, they exceed NEC requirements and classes A, B, C and E of military specifications MIL C-5015C.

FEATURES

Tough, lightweight shell: Strength comparable to mild steel, yet weighs only ⅓ as much.

Anodic coating: Gives shell toughness of case-hardened steel. Takes up to 1800 volts to penetrate coating.

"Sandwich" insulation: Silicone laminate floats between two rigid discs. Silicone disc absorbs shock, lets contacts align themselves freely; rigid discs impart just the right amount of restraint. Gives all advantages of both flexible and rigid mountings.

Chamber sealing: Silicone insulation disc positively and completely prevents water, gas, moisture or dust from passing into shell.

Wide range of pin and socket configurations: Configurations from 2 to 100 poles available. Within each form size all inserts are interchangeable and reversible.

Environmental Limits of Pyle-Star-Line connectors	
Temperature	—80 F. to 225 F.
Pressure	300 PSI External, 200 PSI Internal
Chemical Resistance	Most acids, most alkalis, oil
Corrosion Resistance	Salt Spray: 300 days without failure
Dust Resistance	Exceed requirements of MIL C-5015C
Shock Resistance	50G Minimum
Vibration	Exceed 20G to Method II of Mil C-5015C
Humidity & Moisture Resistance	Exceed Class E. Spec. of Mil C-5015C
Air Leakage	Meet Class E Spec. of Mil C-5015C

Write today for complete specifications.

NATO Budgeteer Holcombe

Points up how quarter billion dollar European missile market operates

John L. Holcombe is Director, Office of Programming and Control, International Security Affairs. Previously he was Deputy Controller for Europe under Lord Ismay and reporting to Assistant Defense Secretary W. J. McNeil. Probably more than anyone else he knows the basics of Europe's defense needs.

Q. *Can you give us a measure of the NATO missile program over the next several years?*

A. It would be misleading to speak of a NATO missile program since each NATO country is responsible for the logistic support of the forces it contributes to the NATO defense effort. Several of the countries are undertaking missile development. While there is concentration on surface-to-air missiles, efforts are also being devoted to surface-to-surface, air-to-air and air-to-surface missiles.

Q. If there is no NATO missile program, have the NATO military authorities taken a position with respect to missiles?

A. The most complete public statement on this followed the Annual Command Post exercise conducted from April 15-18, 1957. Then, Deputy Supreme Allied Commander Europe, Field Marshal Viscount Montgomery, stated that by 1966 we will be in the missile age. NATO strategy, he said, is built on the philosophy of the deterrent. In carrying out their task, the NATO military authorities must be careful not to plan the next war in terms of the last.

Q. How does Field Marshal Montgomery see the next ten years in missiles?

A. I can give you his exact words:

"Strategic missiles fitted with nuclear warheads. The expense and lack of accuracy of ballistic missiles make them unsuitable vehicles for less powerful explosives.

"In some weapons systems, guns will have begun to be replaced by missiles and rockets, e.g., antitank and antiaircraft.

"Short-range guided missiles with ranges up to 500 miles will be available in quantity.

"Intermediate-range ballistic missiles, with ranges up to 2000 miles, will be available and operational from fixed positions from land and ships.

"Man-made satellites will circle the earth.

"Intercontinental ballistic missiles, with ranges up to 5000 miles or more."

Marshal Montgomery considers that while there always will be a need for efficient strategic air forces to provide flexibility and to locate interior targets, the number of aircraft required for interception tasks will be reduced as the effectiveness of air defense by missiles increases. He also considers that piloted aircraft will be needed for limited and cold war activities.

Q. Does Montgomery consider that missiles will solve all the military problems of the Free World?

A. Indeed not. He recognizes that there are many troublesome problems connected with missiles, of which many are technical. Some of the present-day missiles are slow and can be intercepted, and guidance systems can be jammed, which reduces accuracy as the range increases. The ballistic missile is yet to achieve high precision, so that for real accuracy reliance must continue to be placed on piloted aircraft.

Q. What is the United States doing to provide missiles to its NATO allies?

A. Such weapons are included under the Military Assistance Program, including guided and free-flight missiles. Since the United States is the only nation of the Free World producing substantial quantities of missiles at the present time, it is essential that the United States provide missiles to our allies to match the growing strength of Soviet forces, which are being progressively armed with similar weapons. The NATO forces in continental Europe might not long survive a major assault if the United States contingent were the only forces armed with modern weapons, including missiles. Our allies cannot maintain their vital contributions to the common defense if their armed forces are inferior by reason of outmoded weapons.

Q. To what extent is the United States furnishing its allies with advanced weapons?

A. Through Fiscal Year 1957, the United States had programmed $410 million for new weapons, including missiles. Not all of this is grant aid, however. Approximately $136 million represents sales of equipment to Germany and other allied nations. Additional funds will be used in Fiscal Year 1958 to provide new weapons on a grant-aid basis and new weapons will continue to be offered for sale.

Q. What missiles are being made available by the United States?

A. *Nike*, *Matador* and *Honest John* missile systems are among the advanced weapons being furnished.

Q. Roughly what percentage of the $410 million is for missiles and related equipment?

A. Roughly half.

Q. Are we doing anything to provide them with United States missile production know-how?

A. There is now in the United States a team of Italian military and industrial technicians visiting military production and testing facilities. Similar teams from other countries are expected in the future.

Q. Is this the kind of assistance that Secretary Wilson referred to at the December 1956 meeting of the NATO Council?

A. Yes. At that time the Secretary of Defense announced two important steps being taken by the United States to provide NATO forces with modern weapons. The first, already mentioned, is that the military assistance program now includes deliveries to the other NATO forces of certain new weapons heretofore furnished only to the United States forces. The second is that the United States is prepared to make available certain new weapons systems

and equipment, together with appropriate technical data, to those of our allies who are willing and able to utilize them for developing their own modern weapons systems.

Q. Can you break down for us the mechanics of planning and programming missiles capabilities of the NATO powers?

A. The need for modernization of the NATO forces has been studied by SHAPE (Supreme Headquarters Allied Powers in Europe), and SHAPE has stated a list of requirements. These requirements have been reviewed by the United States military authorities, including the Joint Chiefs of Staff, to insure that SHAPE and United States planning are consistent. Because many of the items involved are, or have been, of a classified nature, the security authorities of the Departments of State and Defense have also entered the picture. On the basis of the requirements dveloped by SHAPE and reviewed by the JCS, the Department of Defense has programmed certain advanced weapons to be furnished under the Military Assistance Program. Also, the Department of Defense has indicated its willingness to consider the sale of certain items to those countries which have the economic capability to buy them.

Q. What are some of the ways in which the United States is encouraging European production and development of missiles?

A. Through the Mutual Weapons Development Program, established in 1953, the inventive capability of Western Europe is being added to that of the United States in the race to keep ahead in the development of new weapons. Bilateral agreements have been negotiated with the governments of the participating countries. This means the United States has the benefit of European know-how and vice versa. These technical argreements set forth the details of the projects and the responsibility of the participating country. They also serve as the basis for payment by the United States of specified amounts contributed to the support of the projects which are shared between the United States and the other nation. The results of MWDP projects generally will be made available for the benefit of all NATO countries. Included are projects for guided missiles systems, countermeasures, new and improved radar, etc.

Q. Are there other ways of encouraging European efforts?

A. If a country has a new weapons system that would make a genuine contribution to the NATO defense, it may be considered for inclusion in the Facilities Assistance Program. This is designed to assist the establishment and expansion of overseas facilities for the manufacture and maintenance of essential military equipment, including guided missiles. Projects presently under consideration include several missiles systems and projects for components. The capacity required for missiles propellants has already been established in Europe with the aid of previous projects.

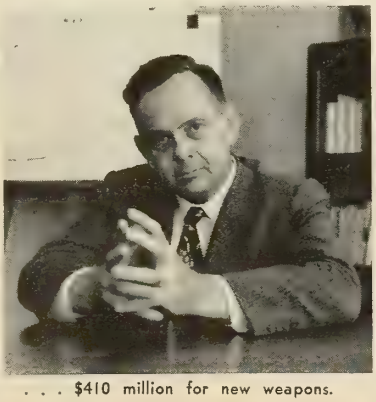
Q. Does the European missile requirement vary materially from that of the United States? If so, how?

A. Yes, the NATO missiles requirements are different from those of the United States—geographical location; distances to potential targets; short warning time. For many tactical applications, however, the requirements will be similar.

Q. Is there any program under way or planned for a simple missile design and development competition in Europe similar to that conducted for the NATO Light Fighter?

A. Missiles are still in their infancy, whereas aircraft have been with us for a long time. It has not yet been possible to establish an environment that would make profitable international competition in missile design. The fact is becoming increasingly clear, however, that the complexities of missiles development and production, and the tremendous costs, will necessitate cooperative and coordinated efforts on the part of the various European NATO countries. This was also expressed by Secretary Wilson in addressing the NATO Council last December. The technical basis for such cooperation appears to be available, in that there are several simple effective systems in Europe. There seems to be an increasing need for coordinated effort, but this has not yet been achieved on a multilateral basis. There have been some bilateral arrangements, however, which are very encouraging.

Q. In programming for the integration of missiles in European defense, have you run into any major political troubles such as from Communist minorities or Soviet blackmail?



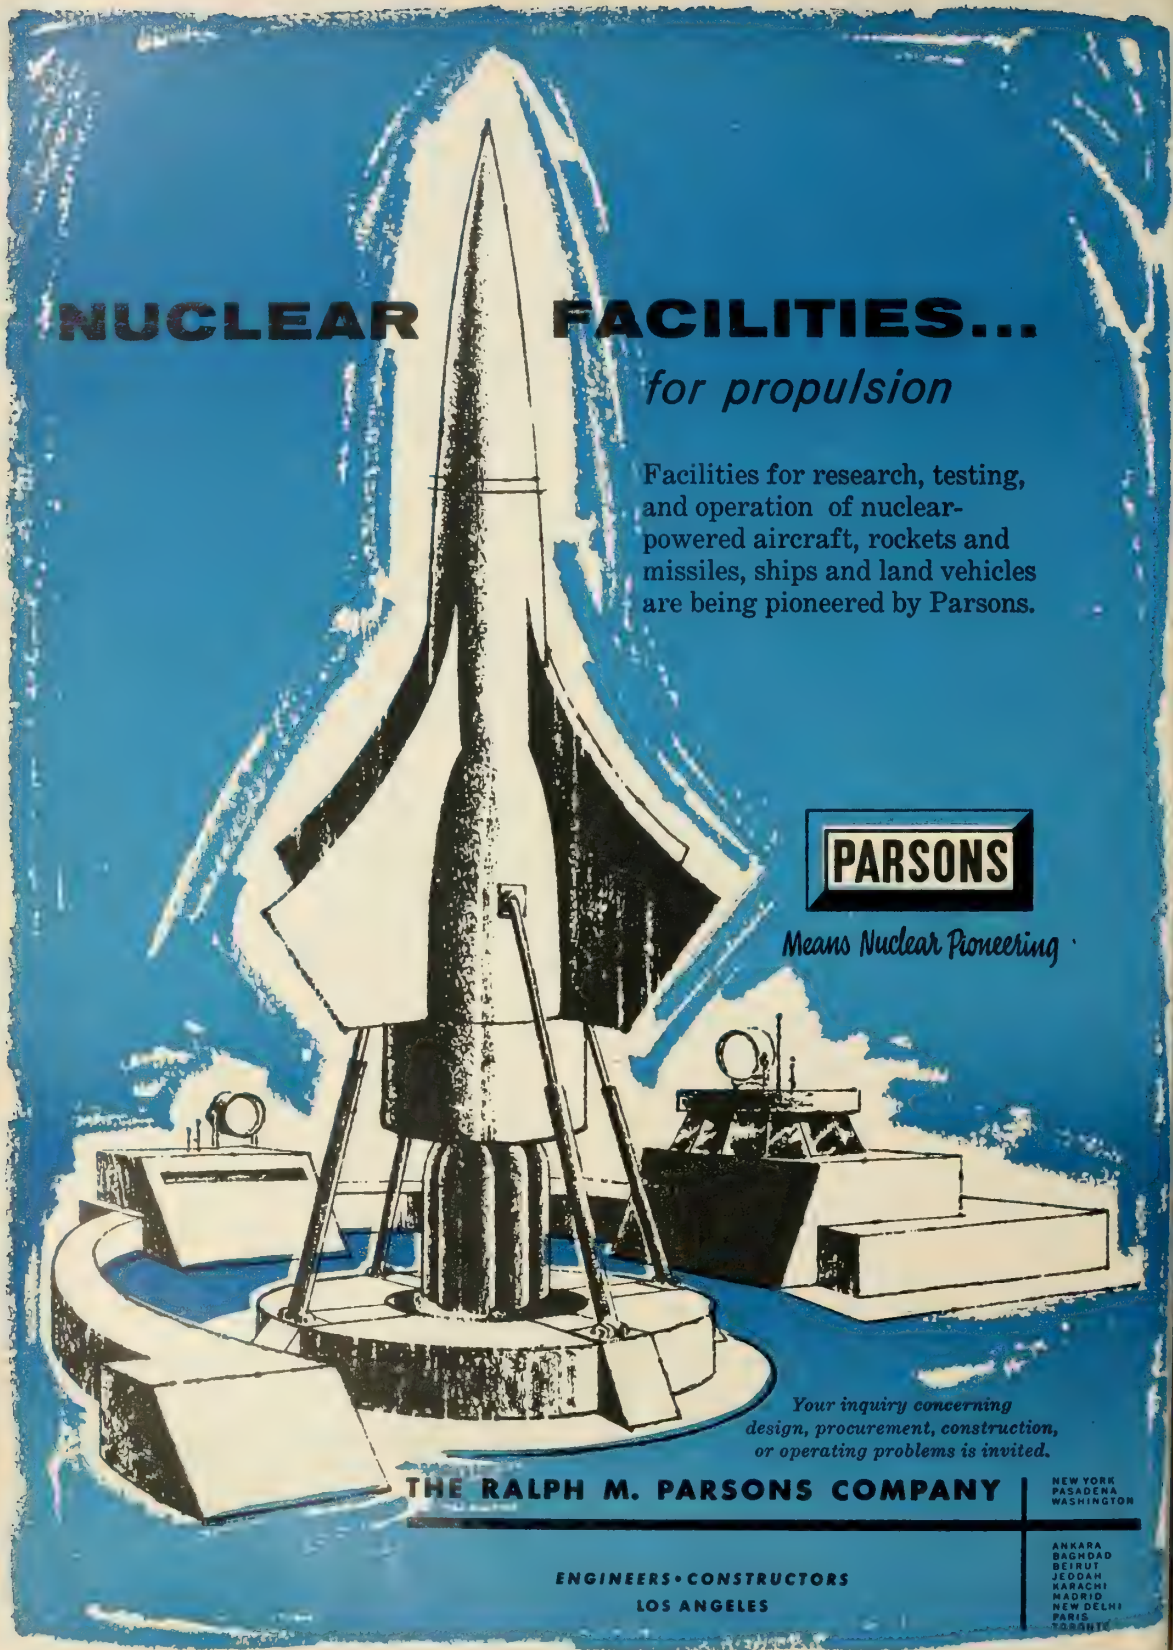
A. No problems involving Communist minorities have yet been encountered in programming missiles for the European defense effort. You are aware of the threats to Norway, Denmark and other NATO governments by the USSR and especially of the similar threats more recently against Western Germany. Such Soviet propaganda efforts can be anticipated against any efforts to strengthen the NATO defenses.

Q. Can you be specific in saying what the views of NATO planners are toward some of the European missiles as operational weapons, such as French, Swedish and British missiles?

A. Some of the European-developed weapons systems are very good. Since Sweden is not a NATO member, however, there is no knowledge of what may be under development in Sweden. The NATO planners encourage the development and production of missiles in Europe. The United States also encourages such efforts. Any data or information regarding European-developed missiles must be sought from the originating country. ★

For Europe in fiscal 1957 . . .

. . . $410 million for new weapons.



Roughly half for missiles.

Sectional Satellites

. . . a bit-by-bit approach to space flight

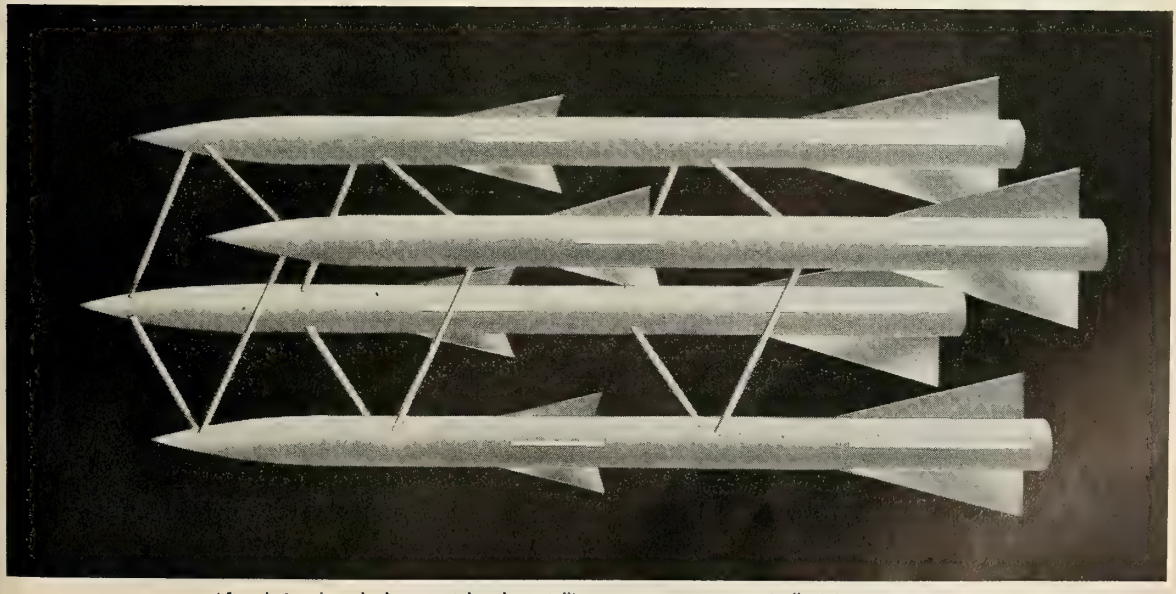
By Commander George W. Hoover, U.S.N.
Office of Naval Research

THE LAUNCHING of the first earth satellite during the International Geophysical Year will be only the first step in a very large research program to gather data which will eventually lead to manned space flight. Before man can venture too far beyond the protective blanket of the atmosphere many satellites must be launched and a vast amount of data must be gathered and analyzed to determine the design of a manned space ship.

As more and more information is sought, the satellites will tend to grow larger and larger, putting an increasing strain on the relatively small amount of power to be derived from presently known rocket propellants. The size of the boosters and each successive stage of the satellite vehicles will increase and the number of stages will multiply until we reach a point of diminishing returns.

Since there is a definite limit to the amount of payload that can be placed in an orbit with chemical rocket fuels, it might be in order to look at another possible way of gathering data over long periods. One possible solution might be a sectional satellite.

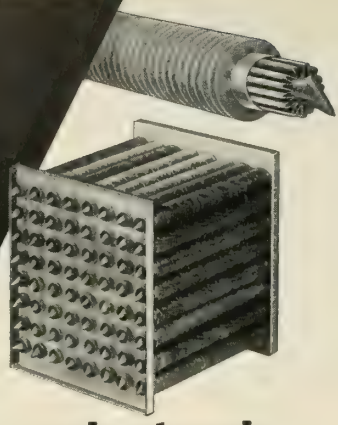
The paramount requirement for any satellite is to stay within payload limitations compatible with the power capabilities of rocket fuels in a system which remains small enough to guide and control efficiently.



Additional requirements call for sending up sensors which are capable of sensing many kinds of information, such as spectrometers, cosmic ray and aurors counters, gamma ray counters, X-ray counters, meteor dust counters, telescopes and many many others. Some of it must be run through amplifiers and computers. All of it must be recorded.

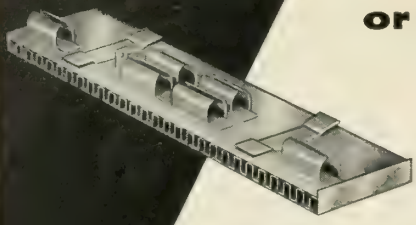
From the recorder it must then be transformed into a signal which can be transmitted at proper intervals to the receivers back on earth. In addition there is the power requirement to operate these devices for very long periods. When the power source is depleted, the satellite will be of no further value except where ground observation techniques can be used. The satellite must also transmit position information.

In order to meet the above requirements it will be necessary either to build one very large satellite or a great many smaller ones. In the case of the very large one the expense will be monumental and such a satellite must be confined to measuring only the information which it was originally designed to gather.



Even with a large power supply it will eventually run down with no possibility for replenishing the power source. Its greatest weakness, however, is a lack of flexibility.

In the case of a large number of



After being launched separately, the satellite components automatically join up in space.

Inner-Fin® Heat Exchangers

or electronic equipment cooling surface

You'll find Dunham-Bush heat transfer engineers ready to serve you.

Whether your problem is aircraft cooling, electronic equipment cooling or some other phase of specialized aero-electronic heat transfer, you'll find Dunham-Bush engineers ready to assist you. This partial list of applications illustrates the type of problems Dunham-Bush engineers have been called upon to solve:

AVIATION

A. Aluminum Units
1. Oil and Fuel Coolers
2. Air to Air Compartment Coolers
3. Evaporators for Compartment Cooling
4. Condensers for Compartment Cooling

B. Stainless Steel Units
1. Air to air heat exchangers

ELECTRONIC COOLING

A. Tubular Heat Exchangers
1. Air to Air
2. Liquid to Air
3. Air to Liquid
4. Liquid to Liquid

B. Plate Type Fin Surfaces

Tell us your heat transfer problem. We'll be delighted to work with you in solving it.

Free brochure "Inner-Fin . . . Miracle Heat Transfer Surface" is yours for the asking. Write today.

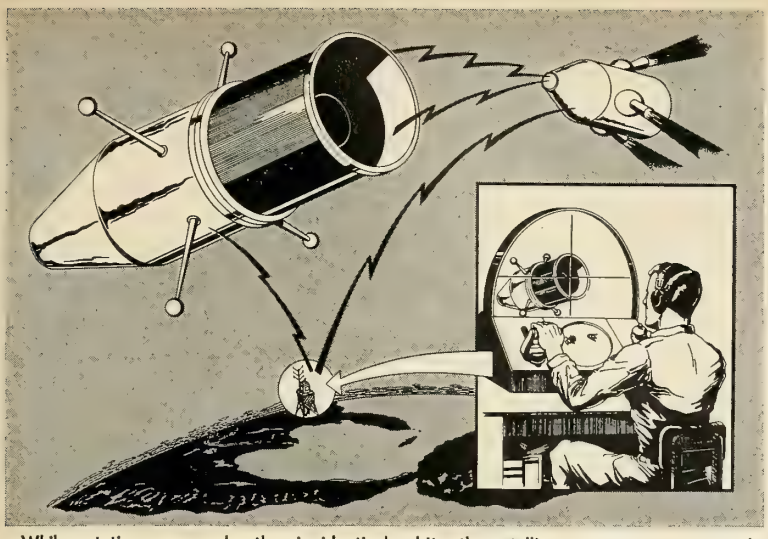
small satellites, each one must carry the necessary components, sensors, computers, amplifiers, recorders, transmitters and power supply. The greatest weakness here will be redundancy without reliability. Each one will operate until its power supply is gone and then it will again be useless except for ground observation. Each will be able to gather only a little data because most of the payload will be used up in the transmitters, recorders and power supply.

Now let's go back to our requirements. First we need a relatively small payload to keep within economical size. This would indicate a large number of small satellites rather than one large one. Further requirements, however, call for many sensors but only one computer, one recorder, one transmitter and one power supply. Ideal satellites would permit addition of sensors as new data is desired and to replenish the power when the supply is run down.

One solution would be to develop a series of small satellites, each as a component in the total system. These components would be placed in the orbit and then connected together. This would permit using relatively small payloads, using the total payload in each unit for the component itself and would eliminate redundancy.



Doubling up on critical components would increase reliability. It would permit replenishing the power supply at any time; and with the proper design of connectors, it would permit flexibility by allowing new sensors to be connected when new data was desired. In addition the basic design of the components as well as the satellite vehicles could be fairly well standardized for large production, thus reducing the overall cost.

The problem of connecting the components could be achieved by one of several possible methods. One way might be to launch the components as a cluster in which each stage would be flexibly connected with other components in that stage. If there were five components to the system, five multistage rockets arranged in a cluster could be used to place the satellite components in the orbit. The flexible connections could be utilized to take care of deviations in trajectory during the firing of the multiple stages.

Such a method would require very good quality control of each of the components in order to insure simultaneous firing of each element in the cluster, but this would be well worth the advantages that could be derived from getting a much more efficient satellite into the orbit.

Many combinations could be used, such as: the elements could be rigidly

Circle No. 65 on Subscriber Service Card.

While rotating near each other in identical orbits, the satellite components are joined together through the use of ground control stations using television cameras as "eyes."

connected using each component in the cluster as firing stage. The only difference here would be in the fact that the stages were arranged in clusters rather than in tandem.

Another method of establishing the connections of a sectional satellite would be to place each component into the same orbit but slightly to the rear of the preceding one. This would require extremely accurate launching in order that each successive section would arrive in the orbit at the proper time and in the proper position.

Errors in orbit could be corrected by using an infrared or magnetic homer which would also bring about the connection of the components. Each successive unit would require a slightly higher velocity in order to overtake the preceding one and some means would have to be included in the last firing stage of each of the satellites in order to clear the way for the payloads to connect. A small jet using compressed air would be sufficient for this action.

Much must be learned about placing satellites into orbits but with the state of the guidance art improving as it is, such a method is not impossible.

A third method would be to affect the connection of the units by ground control. Here the controller would get his information from the unit itself. Each unit would contain a small television or infrared sensor which would look forward at the tail of the preceding component.

By means of small compressed air jets controlled by a simple radio control from the ground, the approaching unit could be plugged into the orbiting unit in much the same way as aerial refueling is achieved. Upon connecting, the television camera could be set to realign itself in order to be used as an observation sensor.

All power to supply these units would come from the main power unit by means of a carefully designed hook-up circuit.

Each component could be added by the same technique until the entire system was assembled. The best order for assembly of the components would probably be to place the power source into the orbit first, the transmitter, recorder, amplifier and finally the sensors. Additional sensors and power supplies could be added as desired.

The employment of a man-controlled system would obviously be more flexible than any self-contained system and would probably come closer to meeting the overall satellite requirements. Since telemetering will be required in any case it seems much more efficient to make use of this means to control and connect the satellite.

Manned space stations will eventually be constructed but a great deal must be learned before this can become a reality. Sectional satellites can teach us how to construct these space stations while being utilized to gather scientific data. It may even be possible to construct the total space station by remote control by building the sections in a honeycomb arrangement and then placing each section into the orbit either in clusters or individually. Unmanned observatories could be built utilizing a sectional technique.

Thus it appears that a sectional satellite would meet the overall requirements for a sophisticated research satellite, accelerate the gathering of scientific data, teach us orbital construction techniques and bring the day of manned space flight just a little closer.★

limitless...

Poly-Scientific's newly perfected manufacturing processes permit limitless variation in design . . . every part custom made to your individual requirements.

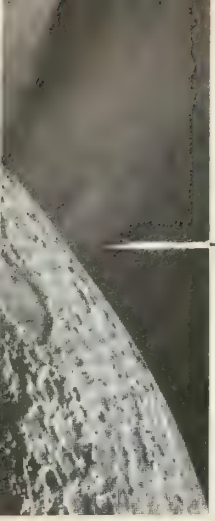
Poly-Scientific is synonymous with versatility, precision, and performance. Every slip ring, commutator and brush assembly made by Poly-Scientific is the ultimate in quality.

The use of epoxy resins allows greater miniaturization without sacrifice of strength. Our perfected techniques permit the use of any of the noble metals and alloys, making possible the selection of the optimum material with the proper hardness for each specific application.

Dependable, long-life performance . . . minimum generated noise . . . freedom from tarnish . . . dimensional accuracy and stability . . . all of these are automatic when you specify Poly-Scientific. And best of all, prices are competitive.

miniaturized slip ring assemblies
brush assemblies
commutators
to fit any requirement

A real achievement in sub-miniaturization: thirty-two 0.140" diameter rings in less than one inch of length, with no sacrifice of electrical or mechanical characteristics! Rugged and accurate stainless steel flange and center rod insure perfect alignment. Solid coin gold rings of 140 Brinnel hardness are finished to a high polish. Also note color coded teflon insulated leads.



This extremely accurate commutator, used to generate a critical impulsing sequence, is fabricated with coin gold segments common to the end contact and P-30 epoxy resin, the combination of which guarantees uniform wear and long life.

missile miscellany

Something else seems to have happened to Vanguard. This page hears reports from people who are privy to the project's secrets that (a) the first stage with the dummy second and third still hasn't been fired, though it's allegedly been "ready" for a few weeks now; (b) that delay may involve alteration of fuel (magnesium or boron-plus-JP4 slurry) or oxidizer (flox) or both. If so, it could mean more delay and expense for the satellite project.

And this page heard and saw demonstrated by one of the World's top solid propellant experts how a dye marker could be landed on the moon within weeks for a total cost of less than $200,000. Heard also from another expert how bombs and rockets will be useless as weapons when launched from manned satellites, skip bombers and other space vehicles.

Then, there was the misdirected telephone call to extension 92658 at the Pentagon which was answered: "Good morning. Unconventional Warfare."

And speaking of changing times and difficult adjustments, let's look at tomorrow today—like *Jupiter,* for example, with the aerodynamic surface of a bullet and an all-welded aluminum skin, and Thor whose toy-tiny fins seem more a concession to habit than a functional necessity. Why fight tomorrow? It's here with more dollars than ever.

And for the day-after-tomorrow, a report, still untraced, of two positrons in a mutually destructive collision and simultaneous, momentary low-energy elimination of the local gravitic field. Whodunit?

Before the Red ICBM we were told that missiles would soon be IT. The airplane had a limited future. Now the Russians have the big bird, and the same people tell us missiles aren't all that good; that airplanes will be the mainstay for many years. Remember, too, how a few weeks ago the anti-ICBM was "years away" and now it's just around the corner? Uh-huh . . .

Now, about that 3000-mile super-radar—it's not all that close, nor necessarily practical. It requires: voltages heretofore achieved only in the laboratory; antennae as big as the Capitol dome; railroad tracks to direct it; a remote location so it won't cook everybody in front of it; and a nuclear power plant. Even then, it's line-of-sight and won't tell the instant an intercontinental ballistic missile is launched.

We're also told "but the Russian ICBM isn't operational." If it will carry a nuclear warhead to within a reasonable distance of a target 5000 miles away, it can be fired from the factory floor! It doesn't need complex mobile logistic back-up like small missiles.

And in case anyone thinks solid-propellant missiles won't get "all that big," this page recently learned of a tooling requirement for a precision lathe with a 140-inch swing and a bed over 45-feet long, center-to-center, needed for finish work on large solid-propellant motor now in design and prototype test stage.

Hawk will be the drone for Hawk. Motorola's revolutionary pulse-light guidance system will keep bird an even 50 feet over any terrain at high supersonic speeds. Hawk, incidentally, is a two-stage vehicle.

Grand Central Rocket Co. has a small rocket-carrying borate solution for fighting brush and forest fires . . . And a sign in a large missile-development laboratory: "We can do it—what is it? We did it—what was it?" . . . 100,000-pound capacity static test stand is going up on one of the islands in the Detroit river . . .

Underwater missile tests are being conducted in Lake Erie . . . Towed models of special hull on West Coast have shown a drag reduction of 80% . . . which makes 60-knot submarines and 600-knot underwater missiles closer to being more than just talk . . . Growing support is noted for very small, high-speed solid-propellant underwater missiles fired in salvo, like 2.75-inch air-to-air rockets; their mission: puncture enemy subs' hulls . . . Navy has turned down small high-speed interceptor-type anti-sub sub as "unnecessary"—eh? . . .

Now a report this page hears of super-hush-hush meeting of nation's top scientists in Old State Department building. The question they ponder: How can this country be defended—from missile-launching subs lurking 15 miles off shore, Red ICBM's, H-bombs, anti-missile-missiles, anti-anti, etc.

Shades of confusion—because of improper liaison between launch-site builders and missile-makers, missiles couldn't be fitted into many of the Nike launch sites. And, antipodally speaking, proof that Japan admires American ways: Japanese Air and Ground Self-Defense forces are raising Nipponese Ned about who should have control of guided missiles. Then, there's the U.S. Vanguard propulsion expert who suggests that if Red ICBM is patterned after Vanguard, it won't work—he probably forgets that the twin-jet Bison bomber couldn't fly either, but does; that the Reds traditionally get a lot more thrust out their engines than we.

And a bitter question: With so much money going for R & D on officers' white dinner jackets, runway vacuum cleaners, etc.—stuff industry should do on its own on competitive basis—why slash basic weapons research?

And out of Redstone Arsenal and ABMA, official insistence that Jupiter be called the Air Force Jupiter and an anticipatory enthusiasm for becoming an AF ballistic missile subcontractor.

At right—wonder what this would do to solid-propellant rocket's specific impulse . . .

America's air power has changed

Space Medicine

By Hubertus Strughold, MD., PhD.

The high-altitude balloon flight of Maj. David G. Simons was a great event in space medicine. This record 32-hour flight, Aug 18th to 20th, with altitude peaks up to 102,000 feet, has demonstrated that man can exist in a sealed gondola filled with an artificial atmosphere and surrounded by an environment which is to a very high degree equivalent to free space.

With regard to air pressure and its functional significance for the human body, the altitude reached is almost the same as the near-vacuum of interplanetary space. This flight, with a plastic balloon developed by Otto Winzen Co., is indeed a breakthrough on the vertical frontier. Behind it were several years of meticulous scientific and experimental preparation. It will be remembered as a heroic scientific and major engineering achievement in the history of human flight. Our congratulations to Maj. Simons, to Col. Paul Stapp of the Aeromedical Field Laboratory and Mr. Winzen.

•

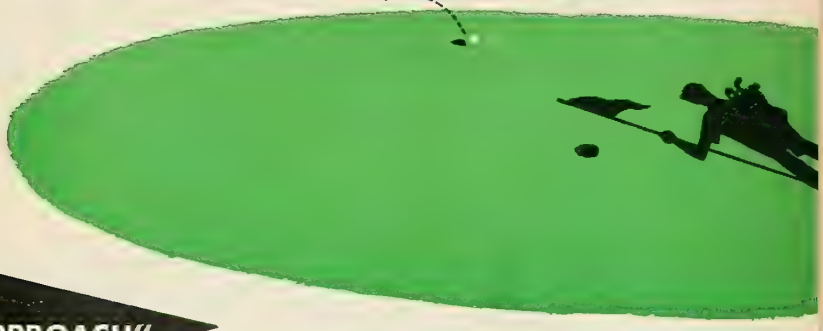
The School of Aviation Medicine, under Maj. Gen. Otis O. Benson, will conduct a three-day symposium in San Antonio on Physics and Medicine of the Atmosphere and Space during the first half of November 1958, the end of the International Geophysical Year. About 40 papers will be presented by physicists, astronomers, engineers and medical doctors from the U.S. and abroad.

•

The American Rocket Society's Human Factors Section, headed by Major D. G. Simons, will have a session at the annual meeting of ARS in December in New York. The writer of this column will be chairman of the meeting.

•

The study of the solar-terrestrial relationship, which is high on the list of the IGY program, is of special interest from the space medicine point of view. Solar flares, for instance, lead to an enormous increase in cosmic radiation. In a paper published in the August issue of the JOURNAL OF AVIATION MEDICINE, Dr. Herman Schaefer of the U.S. Naval School of Aviation Medicine, Pensacola, Fla., reports on the Cosmic Ray Dosage During the Giant Solar Flare of February 26, 1956.



His calculations, based on the sea level influx of neutrons, indicate that in the middle latitudes—twenty minutes after the visible flash of light on the sun—cosmic radiation in the estra-atmosphere regions increased suddenly to very high intensities (about 1000 times greater than normal) and then gradually returned to normal within about eighteen hours. A similar strong solar eruption was observed at the beginning of the IGY.

•

Dr. Syrrel S. Wilks of the School of Aviation Medicine has discovered that green plants like algae, proposed as a source of food and oxygen in space flight, give off deadly carbon monoxide gas. The Randolph Air Force Base pysiologist says this might raise a problem for future space-ship occupants.

"APPROACH" makes a BIG DIFFERENCE!

The Parker "SYSTEM APPROACH" to hydraulic and fluid problems can make a big difference in the performance and efficiency of your hydraulic or fuel system, too.

This "system approach" means that every component will be designed solely for that specific system, so that the whole will do the required job—*better*.

Parker's "system approach" can save you much precious lead time and many engineering hours—with full responsibility for performance.

Why not ask us about it, now?

The Parker Team provides specialized viewpoints to get the right answers. It's the first step in the "systems approach" . . . gives a Parker customer the plus value of leadership in experience, for today's AND TOMORROW'S fluid and hydraulic problems.

1000 TO 1 GEAR RATIO UNIT USED IN BOEING'S BOMARC

Typical of the specialized servo motor work done by the Edison Instrument Division is a size 11 gearhead motor with 1000 to 1 gear ratio. This unit is currently being supplied to Boeing for use in its newest missile project, the Bomarc.

This gearhead motor offers minimum size and weight for systems designers, and extremely fast delivery schedules on units of this type make its use mandatory wherever applicable.

Edison's capabilities in servo motors, servo instrumentation, and associated precision equipments and systems are the result of years of cumulative engineering experience and the best in modern machine shop and quality control facilities. When critical requirements are necessary for servo motors or allied components, or if you'd like to know more about Edison's Systems work, write for *The Systems of the Instrument Division.*

INDUSTRY SPOTLIGHT

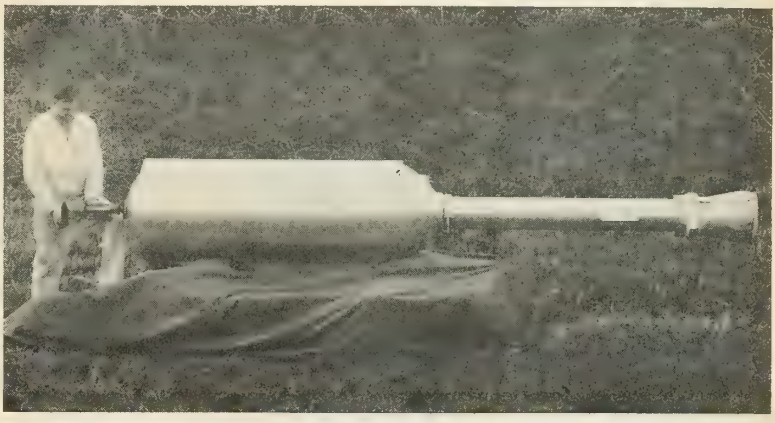
By Norman L. Baker

Thiokol Scores Major Breakthrough in Solid Motors

MARSHALL, Texas—The development of the *Nike-Hercules* sustainer motor, currently in production at Thiokol Chemical Corp., Longhorn Division, was the result of a major breakthrough in solid motor design.

Propulsion units for *Falcon, Lacrosse, Hawk,* and the *Nike-Hercules* sustainer are currently in production here. Although few details have been released about the latter system, there have been a number of interesting disclosures. A photograph of the sustainer unit shows a bottle-like motor which necks down to a long blast tube. At the end of the blast tube is a conventional nozzle. The reasons for these configurations are twofold: (1) to have the center of gravity as far forward as possible, (2) to give an annular space for controls around the blast tube.

Thus, it appears Thiokol has scored two major breakthroughs: ducting the extremely hot gases for a considerable distance and insulating against these temperatures for long burning times. The thrust level, too, is quite high as evidenced by the long flame emerging from the nozzle mouth during firing tests.



The long-burning-time motor is uncooled and is successful because of insulation techniques. This insulation material is probably furnished by Haveg Industries Inc. Machined parts are supplied by Goodyear and Borg Warner.

The motor, which can be touched with the hand immediately after firing, is so little affected by heat that during development several firings have been made by reloading the same hardware. The booster for the *Nike-Hercules* consists of four standard double-base solid-propellant *Nike-Ajax* booster motors.

Under a $5-million expansion program, the Longhorn Division is being expanded. This contract has recently been extended through 1959 and it is anticipated that the Ordnance Corps will make additional demands on this corporation. Rocket facility was designed by Thiokol in 1953 to produce a large volume of small solid rockets such as the *Loki* and a two-inch air-to-air rocket. The plant was put into operation in 1955. Now, with the trend toward a small volume of large solid rockets, production thinking and techniques have had to be revamped.

In 1956, some 800 persons were employed at the Longhorn Division which is located at Karnack, Texas. In addition to the rocket facility, Thiokol is responsible at Longhorn for maintaining a TNT plant in standby, and a pyrotechnics plant in layaway, ready for use as required by the Department of Defense.

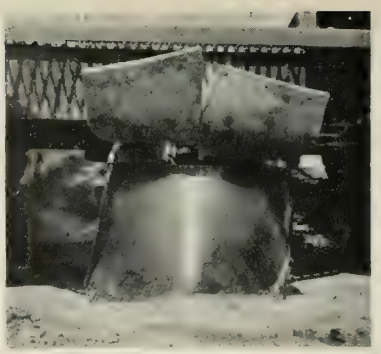
For security reasons Thiokol has not released production figures, but production capacity in 1953 was estimated at about one-half million pounds per month, and it is believed that current capacity is several times that. The primary purpose of this Thiokol-Texas facility is production, although a certain amount of development is carried out. In this regard, The Thiokol Division works closely with Thiokol-Redstone Division and with the two company-owned divisions of Elkton, Md. and Brigham City, Utah.

The NIKE-HERCULES sustainer motor is an uncooled and long burning unit. Success of the motor is due to advances in insulation techniques by Thiokol and Haveg Industries.

The long flame produced during a static firing of the NIKE-HERCULES sustainer motor is indication of a high thrust level. Cooling is so effective motor units may be re-used.

Rocket Exhaust Flame Drills Rock

The rocket exhaust flame is now being put to industrial use. On the gigantic St. Lawrence Seaway project, blast holes are being sunk in rock with a rocket flame process known as Jet-Piercing. Developed by Linde Co., Division of Union Carbide Corp., the new process works on the rocket principle and makes it possible to pierce rock at speeds up to ten times faster than conventional drilling methods.



The Jet-Piercing rig is fed 10,000 cu. ft. of oxygen and 40 gal. of fuel oil per hour. Oxygen is supplied from a trailer holding enough for eight to ten hours operation.

Intensely hot, supersonic jets of flame are the key to the new process. Reaching temperatures of 4000°F, the flame spits out of a rocket nozzle and disintegrates or spalls the rock in its path. This is a continuous operation. Disintegrated rock particles are thrown up out of the hole by the combined force of burning gases and steam so that a fresh surface is continually exposed to the jet flame. The only limitation to penetration depths is the length of the hoses (carrying fuel, oxygen, and water) that are lowered into the hole. Deepest penetration obtained to date is 160 feet.

The rocket flame represents one of the highest concentrations of energy available to man. At its highest velocity, flame has a mechanical energy equivalent of about 500 horsepower—yet this energy is contained in a flame not more than 18 inches long and two inches wide.

Low viscosity fuel oil or a liquid hydrocarbon fuel such as kerosene is combined with high-purity oxygen to produce the intensely hot flame. A blowpipe, suspended from a crawler-carrier, controls flame combustion and action.

The 4000° rocket exhaust flame begins to cut.

Linde has found that their new process works fastest on the class of spallable rocks which normal drilling methods find toughest—especially those containing silica—such as granite, syenite, quartzite, sandstone and magnetic taconite. Potsdam sandstone, the rock being pierced on the St. Lawrence Seaway, is a highly abrasive material that would normally cause excessive bit wear. In the past it has taken as long as a week to drill a 100-ft. hole in this

CUSTOM EXTRUSIONS
ROLL-FORMED SHAPES
AND SECONDARY OPERATIONS

WERNER Aluminum plays a vital role in the production efficiency and sales success of such industries as: aircraft—appliances—curtain walls—electrical fixtures—furniture—railway coaches—storm doors and windows—sliding door hardware—trailers—trucks—buses—TV antenna tubing and masts.

WERNER extrusion and roll-forming services cover all alloys including the High Duty alloys, RR57, RR58 and RR257.

WERNER equipment includes heat-treating and fabricating facilities as well as other secondary operations such as punching, drilling, riveting, cutting, bending, welding. Every manufacturing phase from coil or billet to finished part can be performed in our own plant.

WERNER quality controls guarantee exact conformance to critical dimension requirements and design specifications.

WERNER experience, skill and versatility assure prompt delivery to meet production schedules.

Get facts and data on what aluminum can do for you. Send for this free booklet— **"New Horizons In Aluminum."**

R. D. WERNER CO. INC. ALUMINUM

Circle No. 69 on Subscriber Service Card.

very hard rock using churn drills. But with jet-piercing, a 100-ft. hole can be sunk in a single shift.

In addition to the increased speeds of penetration, Linde's Jet-Piercing process makes it possible to "chamber" blast holes. Chambering consists of enlarging the blast hole at any desired depth so that extra explosive charges can be placed exactly where needed. The operator simply lifts the blow-pipe off the bottom of the hole and lets the jet blast away.

Since Jet-Piercing harnesses thermal energy instead of mechanical energy, the new process also eliminates the maintenance problems associated with churn drills, pneumatic drills, and jackhammers.

AF Seeks More Seattle Space for Boeing

The Air Force is trying to get more space for Boeing's pilotless-aircraft division in Seattle. The Army Engineers' headquarters installation there has been tapped for the space, and a decision on the request should come out of Washington. Air Force has also obtained government warehouses across from the Engineers' HQ for its Boeing-Support program.

AP&C is Sole Producer of Solid Oxidants

The production of the solid propellant oxidants, ammonium and potassium perchlorate. is the sole responsibility of the American Potash and Chemical Corp.'s Henderson, Nev., plant. Production capacity is in excess of present and foreseeable defense requirements. Production will step up on completion of a new plant in Aberdeen, Miss., currently in the planning stage.

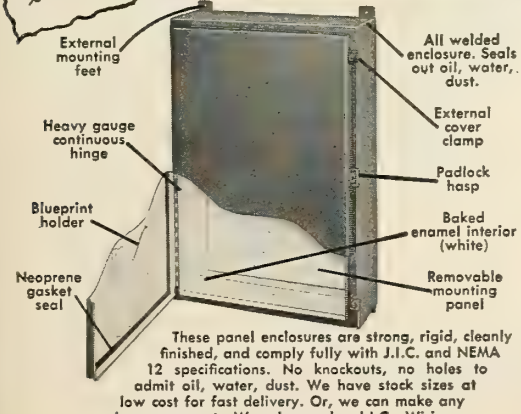
Products manufactured at Henderson are sodium chlorate, potassium chlorate, potassium perchlorate, ammonium perchlorate and manganese dioxide.

The chlorate and perchlorate processes start with the electrolysis of salt trucked from a deposit approximately 90 miles away in California. The primary product, sodium chlorate, is sold commercially and used as a raw material in making perchlorates.

The perchlorate process involves electrolysis of sodium chlorate solution at a platinum anode to produce sodium perchlorate. This is in turn reacted with potassium chloride to produce potassium perchlorate in a company-owned facility, or it is reacted with ammonia and hydrochloric acid to produce ammonium perchlorate in a Navy-owned plant.

The company-owned sodium chlorate facilities are capable of producing considerably more than would be required to run the perchlorate plants at maximum capacity. In addition, the Navy owns sufficient cells to produce approximately 600 tons of sodium chlorate per month. Approximately one pound of sodium chlorate is required to make one pound of potassium or ammonium perchlorate.

Currently sodium perchlorate capacity is approximately 1000 tons per month. There is ample space to install additional cells to bring the monthly capacity up to 1500 tons.



The Navy-owned ammonium perchlorate facility is an integrated unit built on land owned by the Navy adjoining the American Potash plant. Sodium perchlorate is piped to it in slurry form. Power, water and other services are provided by American Potash.

The capacity of this plant is 1200 to 1500 tons of ammonium perchlorate per month for a maximum of 18,000 tons per year. Ammonia is brought in by rail from California producers and hydrochloric acid is supplied from an

adjacent plant at Henderson.

The Henderson plant is capable of producing either ammonium or potassium perchlorate or any ratio thereof up to the total capacity of 1200 to 1500 tons per month.

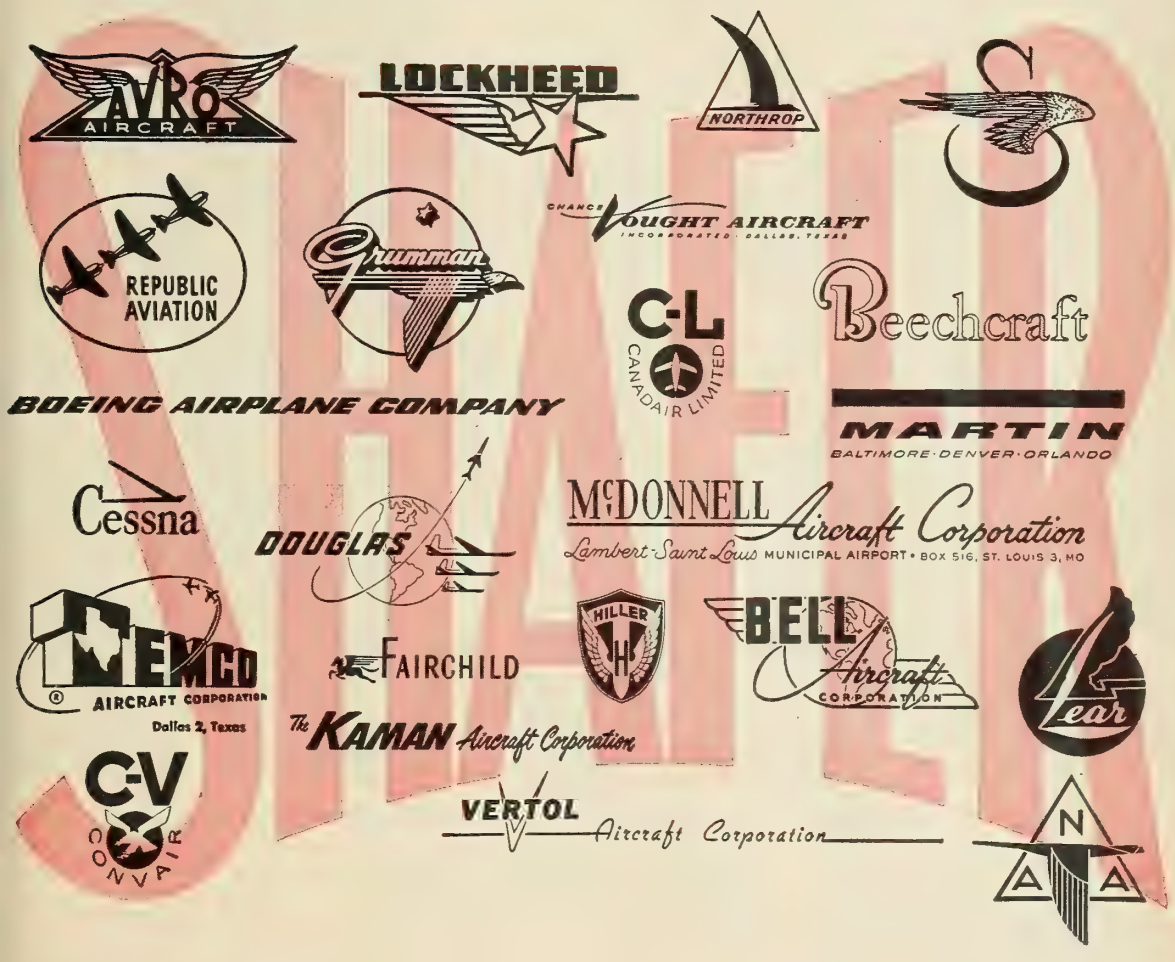
APCC is also engaged in the production of lithium perchlorate. This is only one of the products from their lithium chemical products facilities.

Present price schedule for ammonium perchlorate is in the range of 40¢ to 45¢ per pound, depending on the grade and quantity involved. Increased production would drop these figures substantially.

Current price schedule on ordnance-grade potassium perchlorate, grade suitable for solid-propellant systems, ranges from approximately 25¢ to 30¢ per pound.

In order to further expand their knowledge and technique in the solid-fuel oxidant picture, APCC recently acquired National Northern Corp. of West Hanover, Mass., where large scale facilities are maintained for research, development and production contracts for rocket power development.

Propellex Moves Up In Solid Propellants



EDWARDSVILLE, Ill.—Starting from a basement operation in August 1956, Propellex Chemical Corp., headed by Robert A. Cooley, has moved into its new 100-acre facility located near East Alton, Ill. The security area, comprising about 15 acres, houses an administration and engineering building, plus six other buildings for solid-propellant operation. Buildings house materials storage, mixing, and assembly areas and are well spaced for safety.

Propellex will do research, development and production of solid-propellant devices ranging from gas generators to rockets. The firm is already producing several cartridge-actuated devices. Especially interesting is the Propellex-developed cartridge-actuated landing gear system which takes the place of hydraulics or high-pressure bottles and connecting high-pressure tubing.

Estimated capacity of Propellex is about one-million pounds of solid propellant per year. The facilities will now permit casting solid grains of about 250 pounds. Primary emphasis will be on solid propellants of all types—cast double base, ammonium-perchlorate composite, and ammonium nitrate. Work on fuel binders is underway and a low-energy ammonium-nitrate propellant is "in the works" while a high-energy type—possibly mixed with double base—is also anticipated.

Success of the new firm is based on the fact that it can take advantage

If your problem calls for

MISSILE GO-NO-GO TESTING

Link's Design, Engineering and Production Abilities Provide the Answer

Link has established an enviable record of achievement in the design, development and manufacture of Go-No-Go systems evaluation test equipment. With this experience, Link serves many industries confronted with problems in the field of electronics.

In addition to test equipment, Link's know-how in the rapidly-changing electronics industry covers many other areas, including:

- Simulators
- Evaluators
- Optical Systems
- Ground Support Equipment
- Component Assemblies
- Computers

Experience, highly specialized engineers, and modern, complete production facilities enable Link to custom-build electronic equipment for many missile applications. Each item of equipment—a result of continuous research and development, imaginative management and stringent quality control—is the most advanced in its field.

Link can be of assistance in solving your problem. Write or call Jack Ritchie, Engineering Sales, Binghamton 3-6311 (ext. 277) for complete information. A brochure of our facilities is available on request.

of new solid-propellant advances and rapidly translate them into hardware.

Other operations of Propellex include: preparation of igniter and delay mixes involving zirconium, novel chemicals for heat sensitivity applications and the nitration of special organic chemicals for use in solid propellants.

NAA to Produce New AF Missile

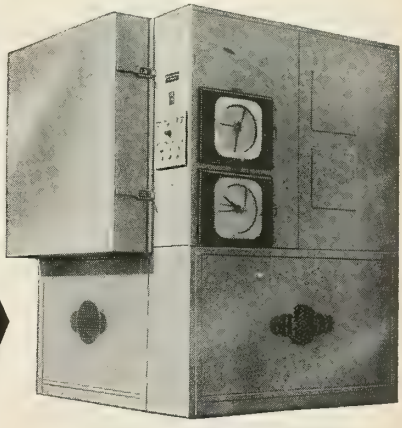
The Missile Development Division of North American Aviation has been selected by the Air Force to produce a new long-range bombardment ASM. According to NAA, organizational ability was one of the chief factors for its selection by the Air Force for the new project.

The company's proposal was selected for its superiority in technical concept and its proposed managerial plan for carrying out the development on a timely basis. The division has responsibility for the weapons system and will have high-priority support from other NAA divisions during the project.

Aeronca Receives *Atlas* Contract

Aeronca Manufacturing Corp. has signed a contract with Convair-Astronautics for a design study program on the *Atlas* ICB. The contract provides for a study in the application of materials in the design and fabrication of the *Atlas*, now in pilot production at Convair.

The initial Aeronca program will cover several months of research and development work at both the Middleton and Baltimore research divisions, and will include application and environmental testing. Aeronca is in the midst of a transition from conventional airframe production to weapons subsystem production.



Lockheed Investigates Nuclear Power for Missiles

Nuclear power to propel missiles of the future is under serious investigation by Lockheed Missile Systems Division scientists. Dr. Louis N. Ridenour, assistant general manager for research and development, revealed that nuclear propulsion studies will be further advanced with a powerful new atom smasher which went into use this week at the Lockheed nuclear laboratory, one of the facilities of the missile division's research and development center located in Stanford University's Industrial Park at Palo Alto, Calif.

West Coast Industry

By Fred S. Hunter

No secret is Lockheed's great desire to establish itself solidly in the electronics field to round out its missile systems division. Not so well known is the fact that it also has its eye on the propulsion field. Senior Vice President Hall L. Hibbard let this cat out of the bag in addressing a management club meeting in Palo Alto, where he told the MSD supervisors the division must get into propulsion.

Power ties in so closely with missiles that propulsion systems should be tailored for each individual weapon, Hibbard said. He pointed out that there have been no really new inventions in missile power that have amounted to anything since the start of missile developments. Liquid rocket engines are simply refined V-2s, he added.

"We haven't scratched the surface in getting energy," Hibbard stated—a broad hint as to Lockheed's course in its propulsion development efforts.

•

It's likely the Air Force will pick P&W's new J52 turbojet engine for the air-to-surface missile for the B-52 to be developed by North American Aviation. Another possibility is two General Electric J85s, but there's less chance for engine failure with one engine than with two and this is a critical factor for an ASM operation. The J52 is a Navy engine, but the Navy undoubtedly would be only too happy to let the Air Force come in for a share of the development costs.

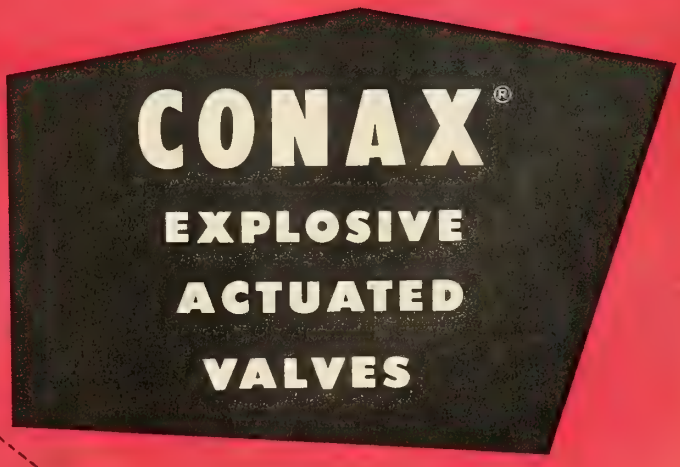
Interesting sidelight of NAA's planning is the shift of Dale D. Myers from chief engineer of the Missile Development Division to project manager on the ASM. One of the factors which won the ASM competition for NAA was its proposed managerial plan for carrying out the development expeditiously.

•

Radioplane's new XQ-4A supersonic target drone, for which it has an Air Force development contract, is a higher performance vehicle than the XQ-4, incorporating a new engine. The needle-like XQ-4 has made a number of quite successful flights in the test program that should be running just about now at Holloman Air Force Base and has set the stage for the new model. The XQ-4A is not a training drone; it's designed for use in evaluating weapons systems.

•

One outward difference between the Rocketdyne test stands at Santa Susanna and Neosho is the sheet metal siding used on the stands in Missouri. That's to permit all-weather operation. The weather in California is, of course, always balmy so the Santa Susanna test crews have no need for this protection . . . This reminds that lately Rocketdyne has been teaching Joplin and Fort Crowder firemen how to handle liquid oxygen. LOX for Neosho's test operations is shipped by rail to Joplin and then to the test area by truck.



•

Hughes Aircraft Co. has been gradually making over its plant at Tucson, where two versions of the *Falcon* rocket are in production—the radar-guided GAR-ID and the infra-red GAR-2A, both used by the Convair F-102A interceptor. Work on the program, estimated to cost $1 million or more, started about a year ago. It is expected to move rapidly toward completion after the new warehouse, being built by the Tucson Airport Authority for lease to Hughes, is ready for occupancy (in the next couple of weeks or so). This will free main building stores space for manufacturing.

•

We wouldn't vouch for the truth of it, but there's a rumor around that it was President Eisenhower himself who ordered the *Navaho* cancelled when he learned the project's cost was $15 million a month.

DELCO HIGH POWER TRANSISTORS

Now available . . .
FOUR new types!
New LOWER prices!

Typical Characteristics at 25° C

	DT100	2N441	2N442	2N443
Maximum Collector Current	13	13	13	13 amps
Collector Voltage, Emitter Open	100	40	50	60 volts
Saturation Voltage (12 amps)	0.7	0.7	0.7	0.7 volts
Power Dissipation	55	55	55	55 watts
Thermal Gradient from Junction to Mounting Base	1.2°	1.2°	1.2°	1.2° °C/watt
Nominal Base Current I_B ($V_{EC} = -2$ volts, $I_C = -1.2$ amp.)	-19	-26	-26	-26 ma
Distortion (Class A_1, 10 watts)	5%	5%	5%	5%

Delco Radio offers four new alloy junction germanium PNP transistors to meet an even wider range of applications. Like all of Delco Radio's High Power transistors, these are characterized by high output power, high gain and low distortion. All, too, are normalized to retain their fine performance characteristics regardless of age. Furthermore—these new types are all in volume production. Other types are available at new, lower prices. Data and application sheets and price lists are available upon request.

Exide missile battery program aims at giving you the battery you need, when you want it, with the maximum assurance of reliable performance

Behind the Exide Missile Battery Program lie the full engineering resources of the Exide Laboratories. Engineers in the Missile Applications Section concentrate exclusively on silver zinc missile batteries designed for applications requiring maximum power with minimum weight and space. At their disposal is the extensive knowledge and background of colleagues working in a wide variety of research and engineering fields related to missile batteries.

Benefit from Exide's experience and facilities—unduplicated by any other battery maker in the world. You are invited to submit your auxiliary power requirements and problems to us for study and evaluation by our engineering staff. special features

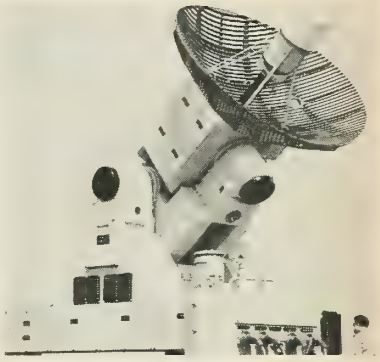
How do we achieve missile electronics reliability? Messrs. G. G. Brown and R. J. Dennis of the Cook Technological Center discuss the problems associated with missile electronics reliability, including the relatively unknown or neglected tools of the trade which can be utilized to advantage in this complex and controversial field (page 172).

Will astrionic instrumentation problems become insurmountable?

The need for more rapid strides in the field of electronic trajectory-measurement systems for missile tests is outlined in an article by American Aviation's Electronics Editor Henry P. Steier. The present basic techniques involved, the systems in current use and possible future systems are considered (page 179).



IRBM guidance gyros—air- or liquid-lubricated?

Ballistic missile guidance technology has led to the development of new techniques and requires a continuous and aggressive program of product improvement, especially in the gyroscope field. Assistant Editor Norman L. Baker, presents a brief history of air-bearing gyro development and details the extreme requirements of a gyro test lab (page 183).

Thermocouples or resistance-type measurements for ballistic missiles?

From a mechanical standpoint, thermocouples are the most reliable tools for temperature measurement on ballistic missiles, according to ABMA's Charles T. N. Paludan. Mr. Paludan explains why—and how these measurements are made in the Army's *Redstone* and *Jupiter* missiles (page 185).

cover picture:

Switzerland's achievements in the missile industry can be credited almost exclusively to the Oerlikon Co. of Zurich. The Oerlikon surface-to-air missile (m/r cover) and its associated ground control equipment is a tremendous achievement for a private company. The missile is equipped with a lock-on and track radar. The track radar controls the beam transmitter and the missile launcher. The beam transmitter is equipped with a fine and a coarse beam. The coarse beam locks on the missile after launching and guides it toward the fine beam. The fine beam then directs the missile to the target. Limited by a computer, which controls speed and accelerations of the beams, the transmitter moves at a rate the missile is able to follow.

BULOVA

FAMED FOR PRECISION SINCE 1875

NEW AM-100

"MULTI-PURPOSE" OVEN

Now Bulova pioneers an entirely *new*, ultra-simplified means of temperature compensation...the "multi-purpose" AM-100 oven.

The AM-100 is designed to yield exacting temperature control of more than just crystals. *Now* entire circuits, components and/or complete sub-assemblies can be housed in one, low cost unit...the highly stable AM-100.

By eliminating costlier, less dependable, heavier and more complex temperature compensating factors, hundreds of design hours can be saved...circuits can be simplified and more dependable, and have a far wider operating range.

THE AM-100 FEATURES: Rugged lightweight construction (less than 7½ oz.); Long life expectancy due to triple insulation on heater winding; High stability ± .1°C.; Standard octal plug-in (stud mounting available); The unit draws 20 watts on initial warm-up, with average dissipation of less than 5 watts after warm-up; Meets vibration tests per MIL-E-5272; Overall 3" diameter x 5" high – cylindrical cavity 1¾" diameter x 2¾" high.

A complete line of precision Bulova ovens are available in quantity, with custom designed units available on request.

THOUSANDS OF "FAULTS" can develop in a guided missile, each capable of causing it to misfire or swerve off-course. Pre-launching check-out takes specialized technicians many hours. Under stress of enemy attack, a small but fatal defect might be missed.

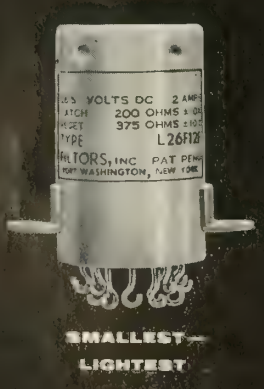
IN MINUTES, NOT HOURS, all critical parts can now be checked by combat personnel—*not specialists* – simply by pressing buttons on truck-mounted RACE system. Connected to missile, RACE flashes discovered faults on television-like screen and automatically ejects punch card indicating repair instructions.

IN FLIGHT, RACE-checked guided missile flashes toward target, performing at the peak capacity engineered into it, with all components functioning to give missile best possible opportunity to reach and destroy objective.

"RACE" TO BOOST MISSILE STRIKING POWER

Electronic System Cuts Launching Time, Ups Dependability

When a rifle bullet misfires you simply fire another. Guided missiles, however, are costly and complex, packed with precision parts in hair-line adjustment. When these "birds" take off, they've got to fly right the first time!



At present, making sure missiles perform properly takes hours, even days, of careful testing by highly trained crews. And under the stress of actual combat, the best-trained crew might neglect an important check-point—and there are thousands of potential trouble-spots in a typical missile.

Sperry's new missile testing system called RACE does the job in only minutes —with little chance for error. RACE (for Rapid Automatic Check-out Equipment) tests all missile components at the launching platform, warns of the tiniest fault, even tells the operator how to fix it. And RACE doesn't make a mistake because it checks itself while it checks the missile. Result is, missiles are ready to launch far quicker and are more likely to perform with full effectiveness.

Designed to test supersonic aircraft as well as missiles, RACE will strengthen our national defense by keeping key weapons fit to fight.

washington briefs

THE PENTAGON IS INTRIGUED by Maj. David Simons' suggestion that we place "platforms" at altitudes in the neighborhood of 100,000 feet. Simons has commented that the platforms would be permanently fixed installations from which scientists could study cosmic radiation and other phenomena indefinitely. A new need for electronics gear?

NAVAL ORDNANCE LAB IN WASHINGTON has developed an electrochemical device which replaces vacuum tubes or transistors in many electronic systems. Known as solion (ions in solution), the device is sensitive to sound, temperature, pressure and acceleration and is expected to be particularly useful in sensing course errors in inertial-navigation systems.

RELIABILITY, RELIABILITY, RELIABILITY is the echo that follows the word "electronics" in Washington's military circles. Most recent and significant echo came from AMC's commander, Gen. Edwin Rawlings, who warned that contracts would be withheld from industry unless reliability greatly improves. "We must," he said, "accept the fact that where we do not have reliability, we do not have the ability to fight."

DEPARTMENT OF THE NAVY has cancelled the *Triton* ramjet missile program, but will support the program long enough to incorporate the missile's best features, namely its "extremely accurate" guidance system, into other missiles.

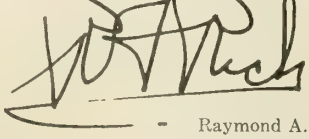
LITTON INDUSTRIES WILL BUY Maryland Electronic Manufacturing Corp., located outside Washington, for an undisclosed amount of stock. Maryland Electronic has current sales figures over $3 million, and will become the twelfth Litton plant.

PENTAGON CONTRACTS FOR ELECTRONICS: Two contracts for closed-circuit TV have been awarded to Hallamore Electronics Co. division of the Siegler Corp. The TV systems will be used for monitoring rocket engine tests at Huntsville, Ala. and the Martin Co.'s facility for *Titan* at Denver. Contracts total about $300,000. Cook Electric Co. will design and construct a missile range instrumentation system at Point Mugu, Calif., under a Navy contract valued at $2¼ million. Gilfillan Bros., Inc. has received a $404,745 contract to cover field-engineering services connected with *Corporal* ground guidance equipment.

THE TELEMETRY GAP between the West Indies and Ascension Island has had Pentagon officials worried. It is now being filled by six Army cargo ships (AGSs) converted to carry telemetry gear.

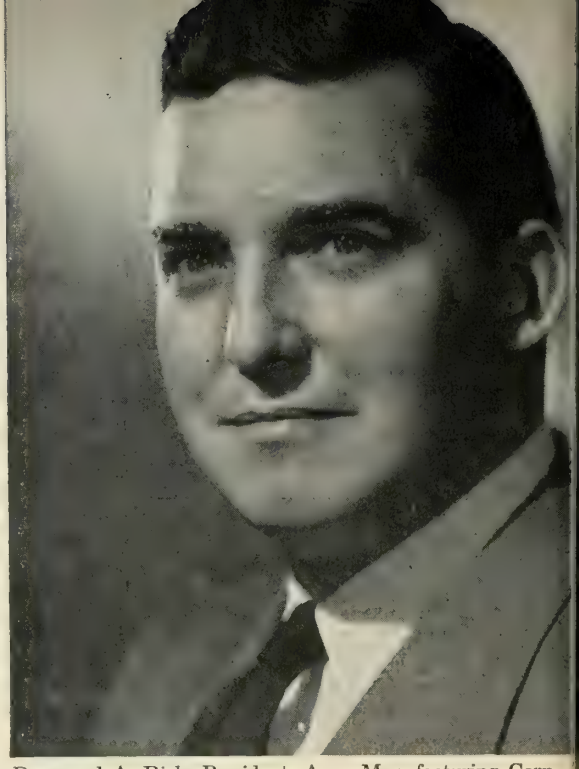
ARMY SIGNAL ENGINEERING LABORATORY nearby has developed a special type solar cell for possible use in satellite power packages. The device has previously been used in research rocket telemetry.

WASHINGTON HAS RECEIVED more evidence of industrial cooperation among NATO members. Compagnie Francaise Thomson-Houston, a French electronics firm, and Decca Radar, Ltd., of Britain, have signed a contract to share equally in providing surveillance radar antennas for NATO air defense.



ASTRONAUTICS CIRCLES IN WASHINGTON are pleased at the news that Lockheed has produced laboratory speeds of 100,000 miles per hour. Shock waves are produced in the company's Palo Alto R&D center by a hydromagnetic shock tube using high-voltage discharges which are boosted to tremendous speeds by magnetic fields. The device's shock waves produce temperatures in excess of 100,000°C, and better shock tubes are in the design stage. Much of the data obtained from the devices are expected to be valuable in the study of space travel.

TO MAKE THINGS BETTER FOR AMERICA—



Avco Manufacturing Corporation is a builder of quality products for the commercial economy and high-performance military systems for national defense. Aircraft engines, electronics systems, farm implements, kitchen components and the nose cone for the Air Force Titan intercontinental ballistic missile are being produced by Avco *today*.

The foundation for Avco tomorrow is being laid at our Research and Advanced Development Division. We know that the technology of the future will be built on scientific research being done now. Amazing new materials and new means for creating useful power hold out the promise of great advances in transportation, in agriculture, in consumer products, in nearly every aspect of our future economy. New scientific knowledge and its imaginative application can turn these promises into reality. Work at the Research and Advanced Development Division has already shown what rapid strides can be taken in a short time.

The division is composed of outstanding scientists and engineers who work in an environment that fosters creative investigation. It is the "breakthrough" division of a progressive manufacturing organization. Avco management recognizes the role of the scientist in modern technology. Avco's determination to make things better for America places the resources of a large, diversified, aggressive company firmly behind the Research and Advanced Development Division.

– Raymond A. Rich
President, Avco Manufacturing Corporation

Raymond A. Rich, President, Avco Manufacturing Corp.

Pictured above is our new Research and Development Center now und construction in Wilmington, Massachusetts. Scheduled for completion early 1958, this ultramodern laboratory will house the scientific and te nical staff of the Avco Research and Advanced Development Divisi

Avco's new research division now offers unusual and exciting career opportunities for exceptionally qualified and forward-looking scientists and engineers in such fields as:

Science:
Aerodynamics • Electronics • Mathematics • Metallurgy
Physical Chemistry • Physics • Thermodynamics

Engineering:
Aeronautical • Applied Mechanics • Chemical • Electrical
Heat Transfer • Mechanical • Reliability • Flight Test

3000-Mile Anti-ICBM Radar Claimed

Line-of-Sight Radar Being Developed in Conjunction with Anti-Missile Missile

A radar capable of detecting intercontinental ballistic missiles (ICBMs) 3000 miles away is under development by the U.S. Though still in the development stage, Gen. Thomas D. White, AF Chief of Staff, announced that the radar will be available for operational use very soon.

The radar would warn civilian and military centers shortly after the enemy ICBMs were launched. Thus, appropriate defensive action could be taken almost immediately. Gen. White predicted that fear of such action would probably deter aggression, and marks an important victory in the military era of electronics.

It would also be an important "breakthrough" in the state of the art. No details as to the nature of the "breakthrough" were disclosed by the general or Air Force spokesmen, since the project is still highly shrouded in secrecy. However, it is logical to assume that the "breakthrough" occurred in the field of line-of-sight applications. Informed sources conjectured that the achievement was the one referred to in a recent Columbia University news conference. At the conference, according to one of the sources, the recent "breakthrough" was hailed as "probably the greatest single advance in radar" since 1939.

Development of the 3000-mile radar nevertheless raises many implications for tactical and strategic operations.

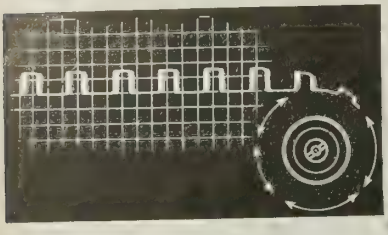
Prime contractors in the development of the radar are the Lincoln Laboratory, Radio Corporation of America, Sylvania Products, and General Electric. No information is available as to who contributed what to the radar.

Operating presumably on the line-of-sight principle, the new radar will be able to see only objects in or above a straight line tangent to the earth. Thus, though it will be able to detect ICBMs at long ranges (because of their relatively high, loping trajectory in the initial phase), it will be unable to detect short-range missiles and low-flying aircraft.

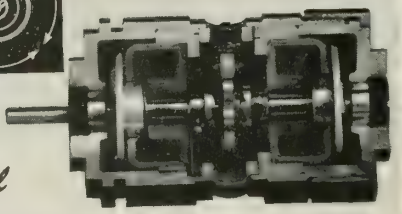
When employed against ICBMs, the radar will enable computers to determine not only trajectory and speed but also size and shape. As a result, it would be possible to determine the specific target in advance, the type of missile used and the location of the launcher. The amount of warning time that would be given for the average missile launched from the Soviet Union would range, it has been estimated by authorities, from 10 to 15 minutes.

Given that much time and knowledge of the trajectory and speed, the most immediate objective of course, would be destruction of the missile. This would imply the availability of an effective anti-missile missile. However, as far as is publicly known today, no such missile exists, although Gen. White in his announcement explicitly stated that one was being developed with utmost "urgency." He was probably referring to the Army *Nike-Zeus* and the more recent Air Force *Wizard* project.

Lacking an effective anti-missile missile, there is a possibility that the military might accept full-effort retaliation as the only recourse. Thus the new radar might signal a total offense.



A missile battle, or even a missile war, might be fought without sufficient time to inform political leaders. Given an equally effective ICBM-detection radar in the hands of the enemy and effective anti-missiles in the hands of both enemy and friendly forces, both sides could conceivably detect and destroy each other's missiles in a matter of seconds or minutes. It would not particularly matter which side fired first. And, of course, if the action took place in the Arctic wastelands, it is quite possible that the civilian population might not know about it.



Telemetry Use For Manned Space Vehicle

Whenever electronic engineers gather to discuss their profession, the question inevitably arises about the future of telemetry when manned space ships come into use. In view of the continuing and increasing interest in the question, we feel it would be helpful to quote from the statement of Mr. Martin V. Kiebert, Jr., director of electronic development at Miami Shipbuilding Corp. Writing in SIGNAL for the eleventh convention of the Armed Forces Communications and Electronics Association, Mr. Kiebert said:

> Manned space craft will probably employ telemetering and remote-control functions (as aided by both carried and ground-based computer facilities) for the following functions:
>
> 1) Telemetry can be used to fix a landing position provided previous facilities have been so established.
> 2) Ground-based radar and computers will be available for landing on the earth; however, the lack of these facilities on the celestial bodies now makes it appear essential that the space craft carry its own radar and high - frequency - response computer system.
> 3) Telemetering may be required on the earth as an advisory means as to when and where landings may be

STEPPER MOTOR

PROVIDES

Bi-Directional

PROPORTIONAL SHAFT ROTATION FOR A GIVEN PULSED INPUT

MODEL SM-300-1

- Angular increment per pulse — 36°.
- Stepping rate — up to 15/second.
- Voltage requirement — 28 V. D.C.
- Duty cycle — $\left(\frac{\text{on time}}{\text{on time \& off time}}\right)$ 56% max.
- Weight — 8 oz.
- Shock — 15 G's for 11 milliseconds duration each way along three major axes.
- Reliability — shall not fail to convert more than one pulse in 1,000,000 into equivalent angular rotation.

OTHER MODELS AVAILABLE WITH VARIATIONS FROM THE ABOVE SM-300-1 SPECIFICATIONS.

The two rotary solenoids contained in each motor produce the incremental motion of the output shaft in either direction. Energizing either of these solenoids produces a combination of linear and rotational motion which moves a ratchet gear axially into engagement with its mating ratchet gear and thus imparts a constant amount of rotation to the output shaft. The detent roller assembly insures constant, reproducible angular shaft rotation increments in either direction and maintains the output-shaft position while the motor is at rest with the power off.

Stepper Motors are adaptable to routine jobs such as driving mechanical counters. They also find excellent use in positioning devices that will set up a controlling voltage and/or a phase shift such as potentiometers and autosyns. They are widely used as a positioner for guided missiles to adjust heading, fuel flow, altitude, and circuit sampling for telemetering purposes. In one adaptation as a heading controller, two Stepper Motors are used to position a differential autosyn in steps of either vernier degree or coarse degrees per input pulse, bi-directionally, through a suitable gear train.

Write for more details—available upon request.

made, and re-orientation of inertial references to the earth's coordinates.

4) The role of telemetering in the landing of extra-atmosphere space craft on celestial bodies. It appears that telemetry will serve as an extremely important element in the landing of space craft on previously unexplored celestial bodies as indicated. Knowledge of both the physical and chemical environment on a proposed celestial body will be essential for survival of both the craft and the crew.

Radioactive Cobalt Aids Missile Recovery

The Era Engineering Corp., Santa Monica, Calif., has announced a radioactive recovery technique to insure post-flight recovery of missile and rocket test vehicles.

Originated by Harold Hutchinson, company vice president and radiation expert, the simple and relatively inexpensive technique has been used successfully on Aerophysics Development Corp.'s Hypersonic Test Vehicle.

In a typical operation, the one-to-two-ounce radioactive source, contained in a one-inch long, 3/8-inch O. D. Allen screw, is removed from its lead shield ten minutes before launching, and placed in the test vehicle by means of a six-foot aluminum rod fitted with a magnetized Allen wrench at one end.

Although the impact point of a vehicle is seldom observed visually or by radar, it is usually known to be within a square of approximately ten miles to a side. This area is searched by flying parallel grid lines about 3000 feet apart in light aircraft or helicopters equipped with scintillometers until the vehicle's radioactive source is detected.

It normally requires three hours to search an area of this size using such a flight pattern, but the results of 40 tests using the radioactive technique produced an average location time of just 30 minutes.

Once the site is located and marked with flares a specially trained recovery crew transports the trailer-mounted lead shield to the impact point, removes the radioactive source with the aluminum rod and places it in the lead shield. The source may be removed from its shield and placed in the test vehicle, or vice versa, in from 30 seconds to one minute.

Under normal conditions, the crew receives negligible and often unmeasurable amounts of radiation. Even in cases where the vehicle broke up in flight, the dosage was not in excess of the daily allowable maximum.

Radioactive intensity is not affected by high shocks or G forces encountered in flight nor will the source itself affect

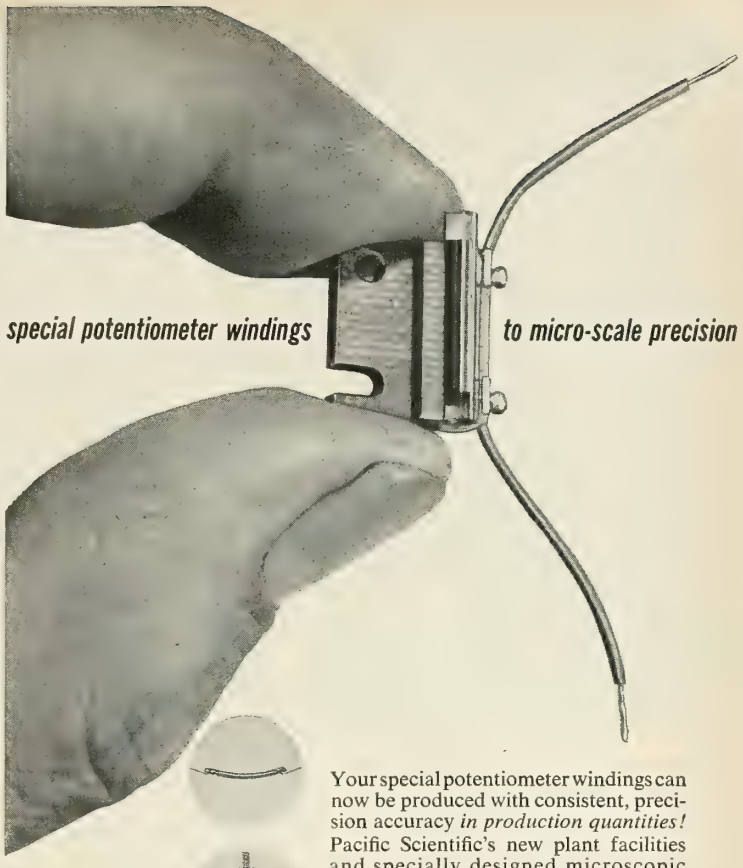
electronic equipment and for short periods has no affect on ordinary film.

The original radioactive source consisted of two Curies of Cobalt 60 with a half life of 5.2 years and an effective lifetime of 20 years. A new source has been recently introduced—four curies of Antimony 124 with a half life of 60 days and an effective lifetime of eight months. The latter was introduced to reduce the hazard if a vehicle impacted in a stable condition, buried itself and was never found.

The company points out that there are many other uses of this recovery technique such as camera pods, instrument packages, propulsion units and material specimens ejected from test vehicles during upper atmosphere studies.

Bomb casings that "dig in" after drop tests may be located by two modifications to the technique: the attenuation effect of the ground can be accommodated by using a more intense source and an isotope which emits high energy gamma rays can be used.

Era can also supply millicurie (1/1000 curie) sources for aircraft flight testing which may be used to locate valuable individual components in the event of pilot bailout or destruction of the aircraft. These small sources require little or no shielding to protect aircraft operating personnel.



The recovery system may be supplied either as a contract service, in which Era provides trained personnel and equipment, including the design and fabrication of source capsules to fit the user's needs, the procurement and storage of the source pellets and the installation and subsequent search and location.

If a user wishes to purchase the equipment and conduct his own operations, Era will furnish all necessary equipment, provide initial training to fit the user's applications, arrange for the supervisor's training course and assist in the application for Atomic Energy Commission authorization.

Sperry's Super Radar To Guide *Talos* SAM

Sperry Gyroscope Co. has developed a "super radar" which the Navy plans to use in the *Talos* surface-to-air missile. The radar unit is said to include many automatic functions and the ability to pick up targets many miles beyond the horizon.

Included in a long-secret class of super-radars developed for the Navy, the SPG-49 *Talos* uses an antenna that resembles a gigantic searchlight. The system is reported to be providing "exceptionally high performance for tenacious, stable guidance of supersonic missiles, whether fired singly or in

Your special potentiometer windings can now be produced with consistent, precision accuracy *in production quantities!* Pacific Scientific's new plant facilities and specially designed microscopic winding equipment can now provide extremely close linearity tolerances on your special designs whether standard or sub-miniature, and in unusual configurations. Elements are wound to your own specifications on glass, Formvar-covered copper or aluminum mandrels, and X-Y recorder inspection assures uniformity of quality.

Pacific's engineering department can also help solve your special problems . . . and complete environmental facilities are available to test to the most rigid military specifications.

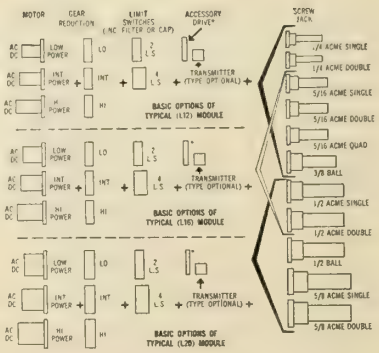
Simplified illustration of Airborne's new modular design concept shows how actuator can be assembled from various combinations of standardized, interchangeable parts. Components actually available appear in the diagram below.



New Airborne modular actuators give you greater design freedom, help eliminate specials

Airborne's new modular concept of linear actuator design is based on a system of standardized components. These components—motors, switches, jacks—are grouped in three broad operating capacity classifications: L12—up to 350 lb.; L16—up to 2500 lb.; and L20—up to 3500 lb. All components within each classification are interchangeable.

As a result, you are no longer limited to a line of, say, a dozen standard actuators whose design is relatively fixed. Instead, you can now select any one of several hundred possible combinations from over 40 standard Airborne actuator components. In 90% of cases, this will give you a linear actuator meeting your capacity and configuration requirements exactly. Thus you have greater design freedom without becoming involved in the extra costs and delays associated with specials.

In addition, while redesigning under the modular system, we have reduced the bulk and increased the capacity of many Airborne actuator components. You get more power in a smaller package, saving valuable weight and airframe space.

Write today for further information on Airborne's new modular actuator line.

Above, the complete line of Airborne modular actuator components.

salvos at individual or multiple targets."

Development of the system was the responsibility of Sperry's surface armament division and the company says that production contracts for the SPG-49 system currently total more than $47 million.

Autonetics Components Tested at 90,000 Feet

Autonetics, a division of North American Aviation, Inc., has successfully carried out functional and environmental testing of components at an altitude of 90,000 feet. The tests, conducted on electromechanical components for guidance and control systems, were performed in a metal-framed gondola carried aloft by a General Mills balloon from New Brighton, Minn.

The gondola was designed by Autonetics engineers, while General Mills provided the balloon and handled launching operations.

Two Advanced Transistors Developed by RCA

A germanium p-n-p alloy-type transistor embodying the "drift" principle and a junction transistor of the germanium p-n-p type have been developed by RCA's semiconductor division.

The compact design of the former opens new applications in military and commercial equipment where space is limited. It operates at frequencies extending from the standard AM band well up into the short-wave bands. It may also be used as a mixer-oscillator and has a high input circuit efficiency, excellent operating stability, good automatic-gain-control capabilities and a good signal-to-noise ratio.

The junction transistor is designed for use in switching circuits of compact, medium-speed military and industrial electronic computers. It has characteristics permitting the design of electronic computers having exceptional stability over wide temperature ranges.

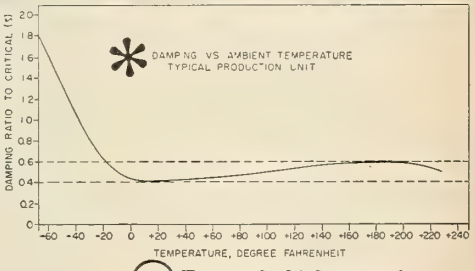
Transistorized System to Measure Liquid Levels

A transistorized electronic system for measuring the level of liquid in any of 100 remotely located storage tanks, with accuracy of performance, reliability and self-checking features has been developed by Texas Instruments Incorporated.

Called the DATA-GAGE, the system was designed and developed to control liquid materials stored in large tanks.

Du Mont Establishes Forward Scatter Link

The successful operation of a complete "forward scatter" communications link in frequencies above 2000 megacycles has been established by Du Mont. According to the company, the path length of the new link is 124 miles, and transmission and reception are at 2180 megacycles. The transmitter is located at Cedar Grove, N. J., the receiver at Somers, Conn., near the Massachusetts state line.



The equipment has been developed and designed for high reliability, ease of maintenance and operation. The design and systems concept allows application of the equipment to both line of sight and scatter communication multichannel links.

The transmitter dish of the system has an 18-foot diameter and is mounted on a 24-foot tower. It is connected by wave guides to a one-kilowatt transmitter utilizing an air-cooled Eimac klystron tube. The transmitter is capable of 72 voice channels with a band-width of 2.5mc.

The SUBMINIATURE PRECISION RATE GYRO

With Constant Damping Over A Wide Temperature Range*

Check these unusual, high standard specifications

1. Constant damping (0.5 ±0.1 critical from −20° F to +220° F)
2. Subminiature size (0.937" dia. x 2.0" long)
3. Outstanding reliability (exceeds requirements of MIL-E-5272A Specs)
4. High resolution
5. Extremely high natural frequencies (up to 43 cps for 1 radian/sec; lower if desired)
6. Variety of motor characteristics available (3φ, 2φ, or split 1φ; 26V or 6.3V; 400 cps)
7. Wide variety of sensing ranges (from 0.5 radians/sec to 20 radians/sec, full scale)
8. Light weight; 3.7 oz.

A unique feature of the transmitter is a magnetic-amplifier-regulated power supply for the klystron, which requires no tubes.

Reception at Somers utilizes two 10-foot dishes on 25-foot towers. The specially designed, highly sensitive 52-tube dual diversity receiver operates reliably on a signal strength of eight microvolts.

Manufacturers Favor Two Annual Trade Shows

The average electronics manufacturer received almost a 50 per cent increase in the number of requests to exhibit his products at trade shows during 1956, according to a survey just made by the Electronic Industries Association.

Cost per show increased from $1712 in 1955 to $1916 in 1956 for the average manufacturer. For parts, tube and semiconductor manufacturers, however, the cost was below the industry average for both years.

Regarding industry attitude toward the increasing number of shows, replies indicated only 13 per cent favor more than four shows a year, and more members favor two shows per year than any other number.

Magnetohydrodynamics: Latest Combined Science

The recent outstanding research work of 11 top U.S. and British physicists and astronomers in the new field of magnetohydrodynamics—combining the sciences of fluid flow and electromagnets—has now been compiled in a volume edited by Dr. Rolf K. M. Landshoff, consulting scientist of the Lockheed Missile Systems Division.

The book, MAGNETOHYDRODYNAMICS, just published by Stanford University Press, grew out of the talks and discussions at a year-end Lockheed-sponsored symposium attended by 200 leading scientists at the company's missile division laboratories in Palo Alto, Calif.

Magnetohydrodynamics, a new branch of physical science, is a study of how magnetic fields influence and are influenced by ionized gases which are brought about at extremely high temperatures.

The foreword to the new book is by Dr. Louis N. Ridenour, assistant general manager for research and development, Lockheed Missile Systems Division. He also presented the welcoming address at the symposium.

This Army Signal Corps DIANA moon radar has been used recently to bounce signals off the moon in efforts to develop a technique for the testing of VANGUARD and other satellite tracking stations. The unit may be used in calibration of MARK II stations.

astrionics

By Henry P. Steier

THERE IS SPECULATION THAT SUPER-RADARS located in the Near East might be spotting flights of Russian IRBMs and ICBMs! Be that as it may, there *has* been a flurry of news on new radar techniques tried by the military. One of these was use of the moon as a reflector for 151-megacycle signals from Army Signal Corp's giant DIANA radar to test satellite tracking stations. Then came Columbia University's announcement of Omnirange Digital Radar for long-range missile detection. ORDIR is said to have a 2500-mile capability for measuring range and velocity with great accuracy. Another report told of Naval Research Laboratory's moon radar antenna made by scooping out earth to form a parabolic reflector over 200 feet in diameter and lining the hole with iron mesh. Navy says it has used the moon as relay station for voice signals.

AIR FORCE IS TRYING ITS OWN APPROACH to calibration of satellite tracking antennas. Cambridge Research Center, ARDC has designed a receiver with time-integrating circuits that allow very low levels of satellite signals to be detected. This in turn should add accuracy to angle information at the instant of satellite transit. It might also allow the antenna to be calibrated by means of radio stars and also be suitable for navigation by radio astronomy.

MOST SENSITIVE SHORT WAVE RECEIVER and farthest reaching transmitter is the new 250-foot diameter steerable radio telescope of the University of Manchester in Great Britain. Beam angle of the telescope will be about one degree at a wavelength of one meter and power gain will be over 16,000. At the wavelength of the spectral line at 21 centimeters, beam angle will be only a few minutes of arc. New detailed maps of radio sources in the sky plotted with the new instrument will add significant new data for use in radio celestial navigation as well as aid studies of the moon, radio echos from meteors and solar-terrestrial relationships.

DURING HIS RECENT TALK AT WESCON on the AF ballistic missile program, Maj. Gen. Bernard A. Schriever put the accent on accelerometer technology to illustrate fields where enterprising electronics firms can make their mark. He said, "Since the interest in mouse traps has begun to wane, the world would probably beat a path to the door of someone who built a really outstanding accelerometer. Most particularly if he could do it for a reasonable price." This column previously noted price of accelerometers as $5000-$10,000 per pound (m/r July 1957).

WORK ON MOVEMENT OF IONS IN SOLUTION UNDERTAKEN BY U.S. Navy researchers may pave the way to devices that replace vacuum tubes and transistors when high sensitivity and low power consumption are vital. The new electrochemical control devices generate current by movement of ions between electrodes in an iodine solution. Current is varied or sustained by stimulation caused by temperature, pressure, light, sound or acceleration. A promising use would be as an integrator in inertial systems. Several hundred pounds of electronics might be replaced by an electrochemical integrator weighing a few ounces.

ARMY IS PLACING MOUNTING EMPHASIS ON ITS RECONNAISSANCE needs for nuclear-age war. Missiles and drones, heavily equipped with new electronic surveillance gear, will probably appear in increasing numbers to form a whole new family of vehicles suiting new Army concepts. These are controllability over greater depth and breadth of area, utilization by higher echelons, increased transportability of input and output systems. Army needs for the new airborne vehicles ought to kick off many electronics-airframe company tie-ins during 1958.

electronics reliability

A sticky art becomes a sensible science as first tools of the trade are developed

By G. G. Brown and R. J. Dennis

Inland Testing Laboratories
Cook Technological Center

THE RELIABILITY PROBLEM has been stated and restated many times. Most engineers concerned with missiles or military electronics have devoted some time to pondering a solution. However, one encouraging sign in the swirl of component reliability confusion is that engineers today are aware that a problem exists, and the terms and phrases of reliability and statistics, failure rate, mean-time-to-failure, confidence limits, etc., are a necessary part of their vernacular. This in itself is progress.

Even though familiarity of the concepts exists, there are still shortcomings. Important aspects of the art are relatively unknown or are being neglected. The tools of the trade are at hand, but who should be using them and how are they to be used? The true value of any tool is in its application and utilization.

To achieve the extreme reliability of complex electronic systems under obtuse environmental conditions, comprehensive component criteria must be established and put to day-to-day use. These criteria (Table I) are the basic tools of the reliability art. It then remains to exemplify how and by whom they should be utilized.

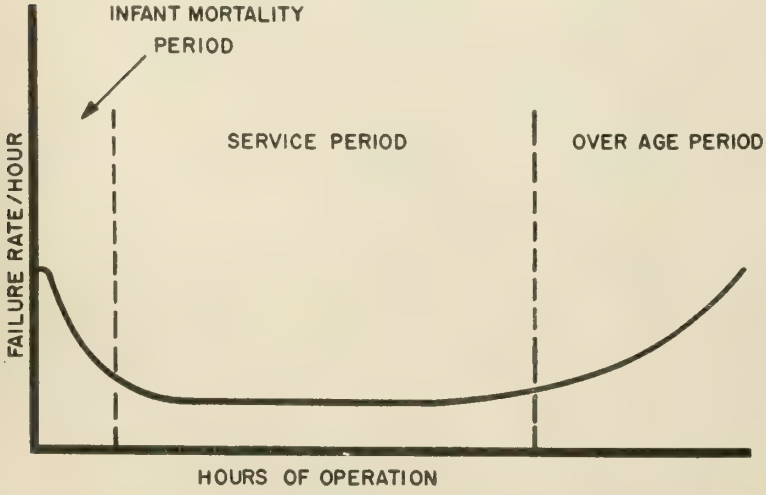

Figure 1. Component failure rate vs. operating time.

Failure Rate Curves

An example of the familiar three-part failure rate curve showing early, random and wearout failures is depicted in Fig. 1. Failure rate per hour is the ordinate and time the abscissa, with the three intervals being defined as the infant mortality screening period, service period and over-age period.

For simplicity, only catastrophic failures are shown. A more useful presentation would include a family of curves as shown in Fig. 2. The catastrophic failure curve is repeated and others added, showing cumulative catastrophic and out-of-tolerance failures for progressively decreasing tolerance limits. These curves take into account the fact that malfunction may occur under conditions that are less stringent than absolute component destruction.

Environmental stress as well as primary circuit stress has a considerable effect on failure rate curves. Failure rate as a function of circuit stress can be combined with the failure rate as a function of environmental stress. This serves to define a surface in a three-dimensional system. An example of such a three-dimensional presentation is illustrated in Fig. 3 where temperature has been added as a third parameter. The infant mortality period is shortened, the useful service period is reduced and failure rate in general becomes progressively higher as temperature increases to extremes.

Parameter Drift Curves

There are many ways by which

component drift may be graphically portrayed. To name a few: the change from the nominal or initial value could be plotted vs. time, circuit stress or environmental stress; the number of components drifting beyond given tolerance limits could be plotted against time; or the percentage of a total component population vs. per cent change in the measured parameter at a particular time.

Fig. 4 illustrates the per cent change in the resistance of two different nominal values of composition resistors during their operational life. A plus or minus 10 per cent design tolerance has been superimposed on the graph and shows that the resistance of the highest nominal value has drifted above this design limit after 8000 hours of operating time. The curves also indicate that the resistance change is relatively independent of nominal value.

The resistors as received were all within plus or minus 5 per cent of their nominal values. Consequently, they could have been ordered as a nominal value at least five per cent lower and still have been within the design specification limits. This would have permitted considerably longer equipment operation before the components drifted above the upper specification limit as shown by curves R_{2a} and R_{2b}.

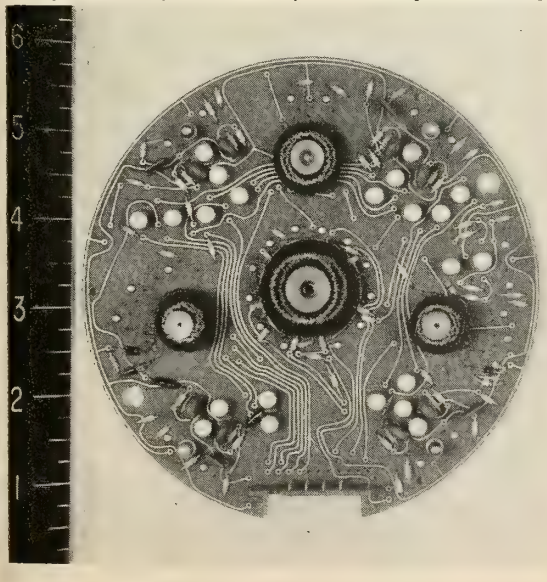
Fig. 5 incorporates the results of parameter drift measurements over a period of 10,000 hours and compares the findings for two test groups of components, each of which is subjected to a different condition of electrical loading (other environmental conditions being the same). The two degrees of electrical loading, one group at 100 per cent of rated and the other at 50 per cent, illustrate the effect of derating on component life.

An initial distribution, derived from measurements made on individual components as received from the manufacturer and prior to environmental exposure, is shown in the first position on the left in the series of histograms in Fig. 5. This distribution shows the per cent deviation of the measured parameter from the nominal component value.

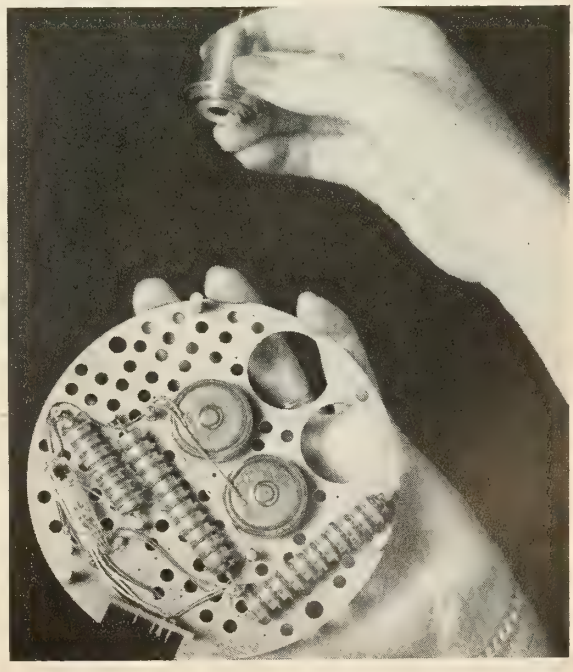
Succeeding histograms, shown for 2000 hour intervals, depict subsequent changes in the component parameter based on the actual initial value of each component. A mean value is computed for each of the aforementioned frequency distributions. Its position is indicated by the point of intersection between the interconnecting dashed line and the ordinate scale for individual histograms.

The path described by the dashed line progressively defines the mean change in parameter as it varies with the period of component exposure to a specific environment. This method of data presentation for parameter measurements enables the user to exercise his preference in considering the performance of the components as individual units or as a group.

Comparison of the two series of curves exemplifies the advantages to be gained by 50 per cent derating of this particular type of component. As an example, consider a circuit in which a change greater than 10 per cent in the component parameter is critical and would cause malfunction of the equipment. At 6000 hours, eight per cent of the units operating at 100 per cent of rated capacity could be expected to be outside this limit (shaded area), whereas all of the derated components are satisfactory.



A critical change in the derated units occurred between 8000 and 10,000 hours of operation when two per cent of the units experienced an 11 per cent change in parameter. Thus, it is readily discernible that a gain in operational life of at least 2000 hours has been realized by derating the components.



Failure Analysis Data

One of the most valuable items at our disposal is the component which fails under known conditions. This is our third basic tool toward the attainment of improved reliability. A study of the basic molecular properties of failing components can be used to determine the mechanics of failure.

Initial studies of component failure indicate that it is possible to get information on the physical structure of a component that could then be applied to 100 per cent incoming inspection of this type of unit. Based on this knowledge, X-ray, electron microscope, spectrographic, or X-ray defraction tech-

Examples of some of the circuitry and electronic components with which missile telemetry and guidance engineers are concerned: Below shows a multi-channel telemetry wafer from the instrument package that will be placed in an orbit in the VANGUARD satellite. To the right is the "eye" and circuitry for measuring ultra-violet light.

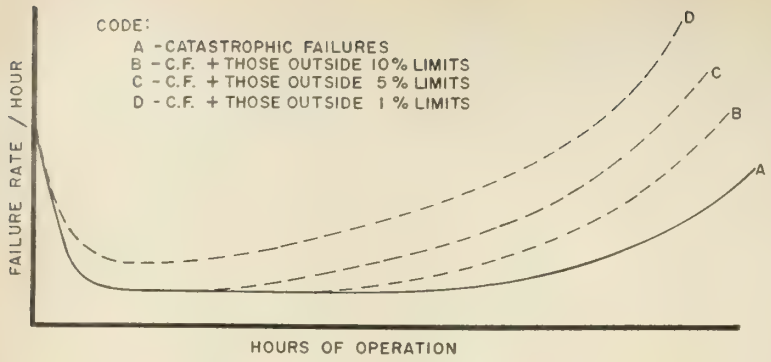


Figure 2. Component failure rate per hour.

niques could be used to screen components which would be potential failures from the total production lot.

Component Screening

Screening of component parts may be done on either a partial or 100 per cent sampling basis. An example of partial sampling is the application of destructive accelerated test techniques to a portion of incoming components. Of much greater value, however, are nondestructive techniques that may be applied to all components that are to be used in the equipment.

Two good examples of 100 per cent sampling are physical inspection and marginal testing techniques. If it is to be used to improve reliability, physical inspection presupposes knowledge of a property or properties of a particular component type which would serve as an indicator of potential failure. For this reason, it cannot be universally applied to all components until extensive studies of the failure mechanism of each individual type have been made. On the other hand, marginal testing techniques are currently used in the computer field for almost all electronic components and have met with great success in this area.

Marginal testing can be defined as operation under more severe conditions than are normally present, but that are still within the individual component's rating. An example of such a test would be operation of diodes with −50 volts reverse voltage applied and 20 milliamperes forward current, where normal operation is at −2 volts reverse voltage and 1 milliampere forward current. The −50 volts and 20 milliamperes are within the diode ratings, so the components should not be overstressed.

What benefits are to be gained by the use of component screening in actual practice? The information presented in Table II demonstrates how component reliability could be substantially improved by screening 90 per cent of the potential failures that would otherwise have been used in the equipment. It is based on the exponential failure law:

$$P_s = e^{-N\lambda T}$$

where

P_s = Probability of survival
λ = Failure rate per unit of time
N = Number of components of a specific style
T = Desired period of failure-free operation

This law is applicable to equipment which has a constant failure rate and where the probability of survival, computed during the life span of the device, remains unchanged. Under these conditions, the probability of survival (P_s) will vary exponentially when evaluated for different periods of failure-free operation (T).

Table I

Tools of the Trade

1) Failure Rate Curves or Reliability Indices
2) Characteristic or Parameter Drift Curves
3) Failure Analysis Data
4) Component Screening Techniques
5) Trade-off or Compensation Techniques

The benefits of screening can best be demonstrated by considering a piece of electronic equipment composed of five different types of components, each type having one of the failure rates that are shown in Table II. The probability of survival for this equipment would then be equal to the product of the probabilities of survival for the several different styles of components which make up the unit.

$$P_s \text{ (group)} = P_{s1} \times P_{s2} \times P_{s3} \times \cdots\cdots \times P_{sn}$$

From this relationship, the calculated probability of the equipment surviving for 10 hours, if initial component screening was not employed, would be 0.51, and approximately 50 per cent of the units could be expected to fail during any 10-hour operating period. On the other hand, if preproduction component part screening was conducted, the probability of equipment survival would be 0.935, thus obtaining an increase of more than 40 per cent in survival probability by utilizing screening techniques.

Trade-Off Techniques

The word *trade-off* usually brings to mind the idea that something irreplaceable is lost, and therefore some doubt is cast on the benefits which can be derived by utilizing this technique. But the gain may outweigh the loss. A good example is the use of negative feedback in amplifier design. It is true that negative feedback has one basic disadvantage—it reduces the over-all voltage gain, but its many advantages such as improved frequency response, increased signal-to-noise ratio, improved stability and reduced distortion more than compensate for this loss.

Some examples of trade-off or compensation techniques which may be applied to reliability are: (1) Derating or load compensation, where the component is operated at a reduced load condition to increase service life; (2) environmental compensation, where

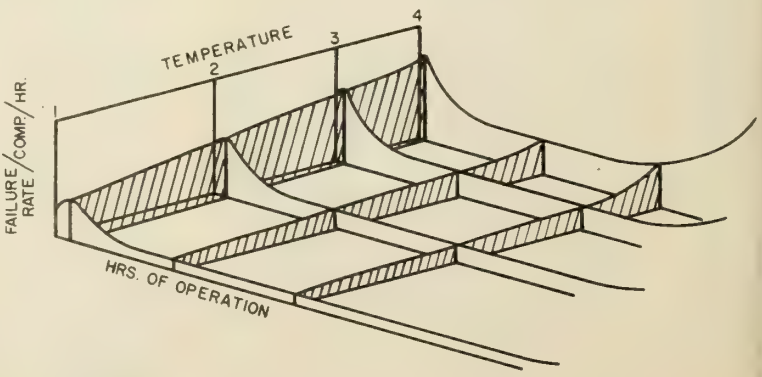

Figure 3. Effect on component failure rate by increase in temperature.

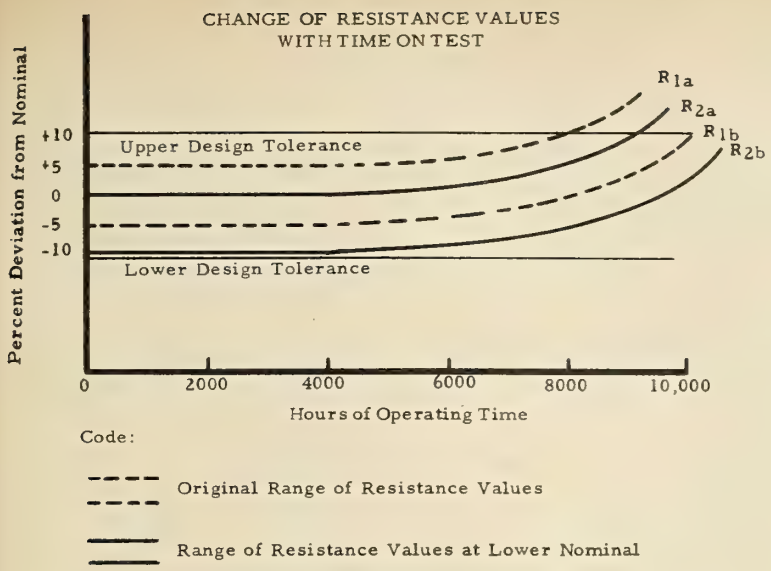

Figure 4. Change of resistance values with time on test.

weight and size are sacrificed to provide insulation or cooling to reduce the components' operating temperature; (3) redundancy, where substitute or parallel parts come into use upon failure of the primary circuits; and (4) compensation for drift characteristics in which components are chosen with opposite drift characteristics. Judicious use of these techniques can greatly improve the over-all system reliability.

After exploring the use of tools and techniques, consider again the question raised at the beginning: "Who should be using them and how are they to be used?" The obvious answer is the design engineers, component application engineers, and quality control engineers. However, the techniques which have been presented can also be utilized by purchasing department personnel, test engineers and field service engineers. Each of these individuals or groups can gain invaluable information from the reliability data and curves that have been brought up, and thus contribute to an increase in equipment reliability.

Use by Design Engineers

During the equipment design stage, many decisions must be made by the design engineer that would be substantiated by component capability data. Component reliability indices or failure rate curves provide information in the initial design stages to establish the feasibility of the preliminary design; environmental stress failure rate curves pinpoint the critical areas where trade-off techniques would be effective; and component derating and characteristic drift curves provide guidance for the application of these techniques. For example, if the circuit designer has knowledge of parameter drift with time

Table II

Improvement of Reliability by Screening

Per Cent Failure Rate/1000 Hours	Probability of Component Group Survival for 10 Hours*	
	No Screening	With Screening
0.1	0.99	0.999
0.5	0.95	0.995
1.0	0.90	0.99
2.0	0.82	0.98

*Figures based on a quantity of 1000 components and 90% screening of potential failures.

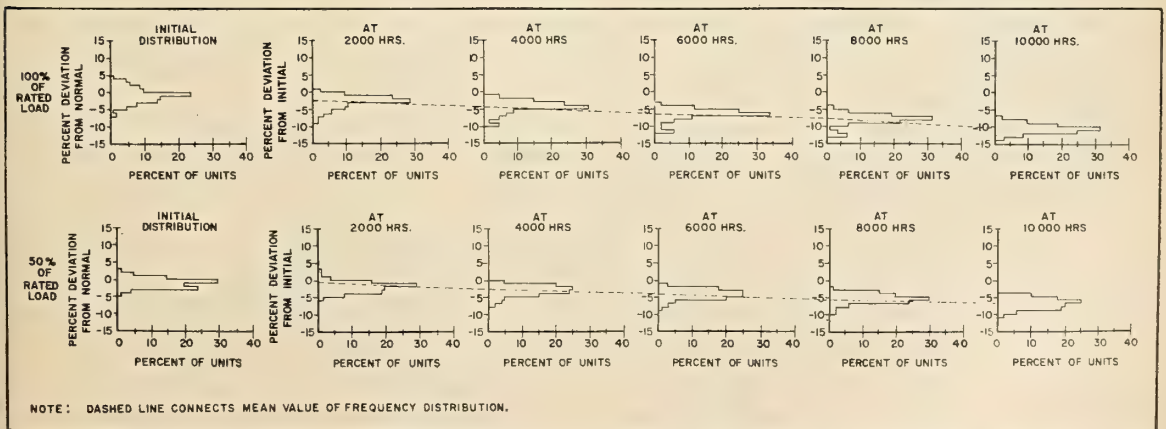
for component types under various conditions, it is possible to select two or more components with compensating drift. An example of such an application to the design of an RC timing circuit is shown in Fig. 6.

A composition resistor used in the circuit increases in value with operating time. A capacitor could therefore be chosen which had a negative drift characteristic, thereby providing little or no change in the circuit-time constant during the operational life.

Parts-Application Engineers

Parts-application engineers are responsible for determining a component's suitability for a particular application and serve in a consultant capacity to the design engineers. They should have at their disposal component failure rate, derating, and characteristic drift information. Many uses will not require the most reliable components available, and these engineers select the most economical components for a particular application based on failure rate data.

Characteristic drift curves will assure optimum selection of nominal values; if a component characteristic drifts in an upward direction during its operational life, as previously illustrated in Fig. 4, then one would want to select a nominal value somewhat



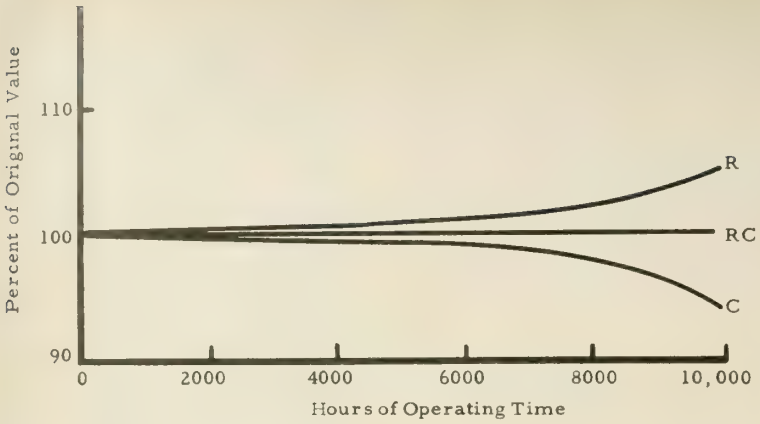


Figure 5. Per cent deviation in component characteristic for operation at 100 per cent and 50 per cent of rated load.

Code:

R - Resistance

C - Capacitance

Figure 6. Drift trade-off in R-C circuit.

lower than when relatively little drift is anticipated.

Control and Test Engineers

Quality control and test engineers can utilize the wealth of information in failure rate and characteristic drift curves, failure analysis data and screening techniques for design of test procedures and to substantiate test results. This information would indicate which tests are likely to be most effective for a particular component type and provide confidence in the test results from a small sample when correlated with the accumulated reliability data. The shape and duration of the infant mortality period of the failure rate curves are important factors in the selection of production tests, for it is quite conceivable that these tests could decrease rather than increase the equipment reliability if the components were inadvertently overstressed.

In conjunction with the purchasing department and application engineers, quality control and test personnel could apply their combined knowledge to the design of procurement and acceptance specifications to assure that the components which are ordered and received for production use meet the required standard of reliability.

Field Service Engineers

Preventive maintenance is a necessary adjunct to the present complexity of electronic systems, and requires a vast pool of highly trained personnel to assure continued equipment operation. Many of these maintenance programs consist of a systematic removal and replacement of equipment components before their useful life has been achieved.

This may not be good practice for two reasons: the first and most obvious is the expense involved for labor and materials; and the second and more important is the danger that the replacement part is not as reliable as the original, or that the replacement technique, such as soldering, has introduced another factor of unreliability.

By applying the knowledge that can be obtained from failure rate curves, preventive maintenance programs could be streamlined or realistically redesigned. Utilization of marginal testing techniques could also be an important factor in these programs to determine when a component needs to be replaced.

The road to reliability lies in the proper engineering application of component parts. These are the basic building blocks of our electronic systems; but before they can be intelligently applied, we must know their strong points and weaknesses, their failure and shortcomings.

Where can reliability information be obtained? Valid, but limited, component capability data is available in reports such as those prepared by ARINC, Vitro, BuShips, etc., and in some cases in component manufacturers' literature. But the scope of this endeavor must be greatly broadened if the degree of reliability necessary for today's complex systems is to be achieved. A concerted attack must be made on the "reliability barrier" by exchange of information among manufacturers and by systematic preparation of handbooks such as those available in the mechanical and structural engineering fields.

The task ahead is formidable, but by no means insurmountable. To attain our goal—elimination of the reliability barrier—industry and government agencies must sponsor the preparation of electronic component handbooks. Furthermore, the entire team, from designer to field service engineer, must become well-versed in the proper utilization of component capability data. ★

ENGINEERS

. . . cross new frontiers in system electronics at THE GARRETT CORPORATION

Increased activity in the design and production of system electronics has created openings for engineers in the following areas:

ELECTRONIC AND AIR DATA SYSTEMS Required are men of project engineering capabilities. Also required are development and design engineers with specialized experience in servo-mechanisms, circuit and analog computer design utilizing vacuum tubes, transistors, and magnetic amplifiers.

SERVO-MECHANISMS AND ELECTRO-MAGNETICS Complete working knowledge of electro-magnetic theory and familiarity with materials and methods employed in the design of magnetic amplifiers is required.

FLIGHT INSTRUMENTS AND TRANSDUCER DEVELOPMENT Requires engineers capable of analyzing performance during preliminary design and able to prepare proposals and reports.

FLIGHT INSTRUMENTS DESIGN Requires engineers skilled with the drafting and design of light mechanisms for production in which low friction, freedom from vibration effects and compensation of thermo expansion are important.

HIGH FREQUENCY MOTORS, GENERATORS, CONTROLS Requires electrical design engineers with BSEE or equivalent interested in high frequency motors, generators and associated controls.

Send resume of education and experience today to:
Mr. G. D. Bradley

Electronic Cooling Package...by AiResearch

SPECIFICATIONS OF TYPICAL AIRESEARCH COOLING PACKAGE

Air Flow	60 CFM
Fan Air Inlet Pressure	18 PSIA
Fan Pressure Rise	1.2 inches water
Heat Exchanger Pressure Drop	1.0 inches water
Liquid	Water Methanol (70% Methanol)
Liquid Flow	0.4 GPM
Heat Rejection*	300 Watts
Fan Power	30 Watts, 110 V., single phase, 400 cycle
Package envelope dimensions	7 x 6 x 3 inches
Package wet weight	2.5 lbs.

*Assumes Class A (85°C.) electronic components, liquid inlet temperature to heat exchanger, 55°C. Includes heat from fan motor.

This high performance AiResearch package cools sealed and pressurized electronic equipment. The fan circulates air through the liquid cooled heat exchanger and over electronic components in a hermetically sealed module. Air cooled units are also available. Fan and heat exchanger are designed, built and packaged by AiResearch for matched performance. Package size is tailored to your individual cooling requirements.

The Garrett Corporation, through its AiResearch Manufacturing divisions, is an industry leader in components and cooling systems for aircraft, missiles and nuclear applications. This wide experience is now being offered to the electronics industry to provide a cooling package to meet any cooling requirement. Send us details of your problem or contact the nearest Airsupply or Aero Engineering office for further information.

ICBM and anti-missile missiles force reassessment of measurement technique

new missiles strain test art

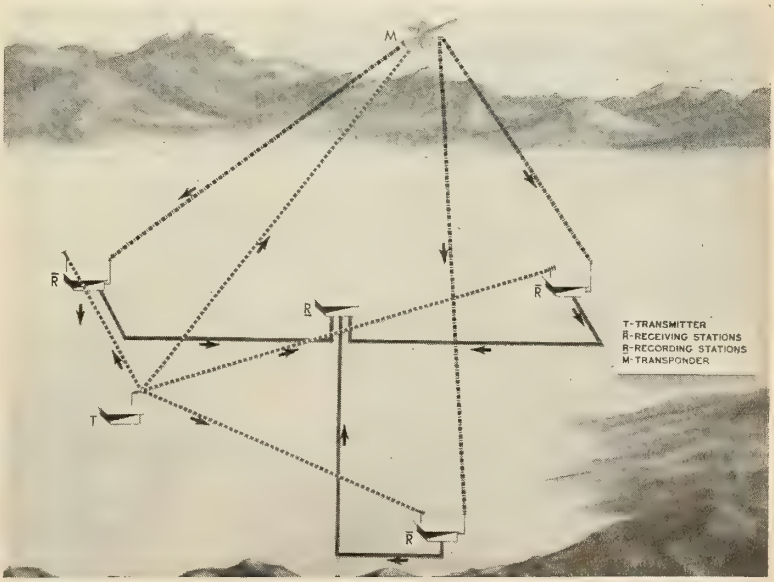
by Henry P. Steier

PERFORMANCE REQUIRED of present-day missiles has begun to strain the capabilities of available astrionics instrumentation to check performance. This condition will be aggravated when flight tests on ICBMs and anti-missile missiles get under way in the near future.

Much of the success of future missile programs depends on more rapid strides in the field of electronic trajectory-measurement systems for missile tests, according to a paper delivered at the Western Electronic Show and Convention by Vernon L. Miller, White Sands Proving Ground, N. M.

"The task of instrumenting the present and planned missiles presents some nearly insurmountable problems. The expense involved in missile tests and the shortage of range time precludes the firing of large numbers of missiles with a hit-or-miss evaluation technique. The least expensive and most expeditious course is to fully instrument a limited number of missiles. Some of the problems placed on the present systems are quite severe. It is these more severe requirements that present today's problems, and these are the problems which must be solved if missile development programs are to attain success while remaining within reasonable development times."

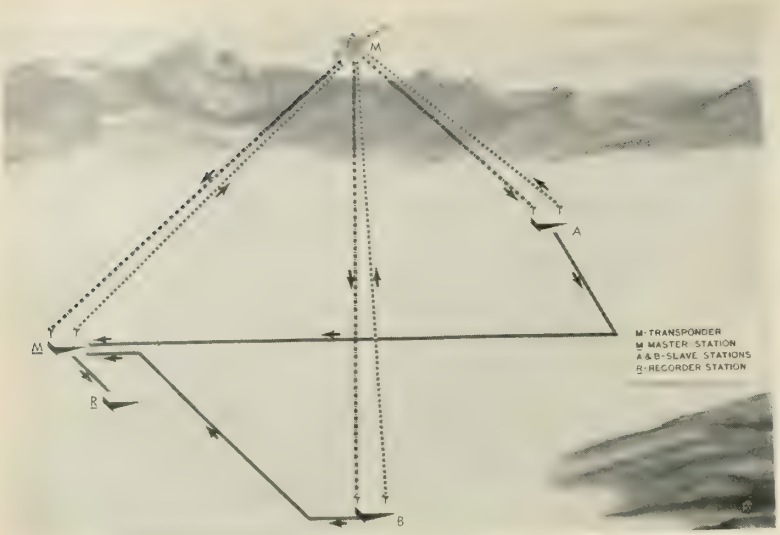
Typical Future Requirements



The precision with which the burnout conditions of an ICBM ballistic missile must be measured typifies measurement conditions facing designers.

If the missile has a 5000-mile range with a circular error probability (CEP) of one mile, a velocity measurement error of one meter per second or an angular measurement error of 0.01 degree is excessive to the performance design tolerance of the missile.

Such tolerances would give a measurement error greater than the specified CEP of the ICBM. Added to the close measurement required is the handicap of making the measurement hundreds of miles from the nearest instrumentation facility. Even with short-range missiles, the difficulty is present since these may have smaller specified CEPs.



Instrumentation of the anti-missile missile goes beyond ICBM requirements. Measurement of needed miss-distance data will be strained by the high closure rates. Miller says these will be in excess of Mach 10, and it will be "next to impossible to predict within 25 miles or more where the encounter will occur."

Add to this the safety problem. High maneuverability is needed in ad-

Electronic trajectory measuring system using Doppler effect. In missile, signal is doubled in frequency and sent to receiving stations for analysis at different positions.

← Circle No. 85 on Subscriber Service Card.

Phase measuring system. Stations send and receive a signal in sequence. Phase shift is proportional to change in path length. Station gets independent readings.

dition to high speed. Position data required during an anti-missile missile test flight must be not only highly precise but instantaneously available to prevent the anti-missile missile from going hundreds of miles off course and doing damage in event of guidance-system failure.

The high-altitude research rocket presents its own stringent problems. Necessary accuracy for position might be within one meter, and velocity within 0.1 meter per second while the vehicle is at 200 miles altitude.

Such measurements mean obtaining accurate data within three parts per million. On an angular basis it amounts to measurements within 0.6 seconds of arc.

Basic Techniques

At this time there are about 30 electronic trajectory systems in use or in development. A basic similarity between the systems is measurement of radio-signal propagation time. The measurement is done in different ways. These form different geometrical configurations of data-acquiring equipment stations.

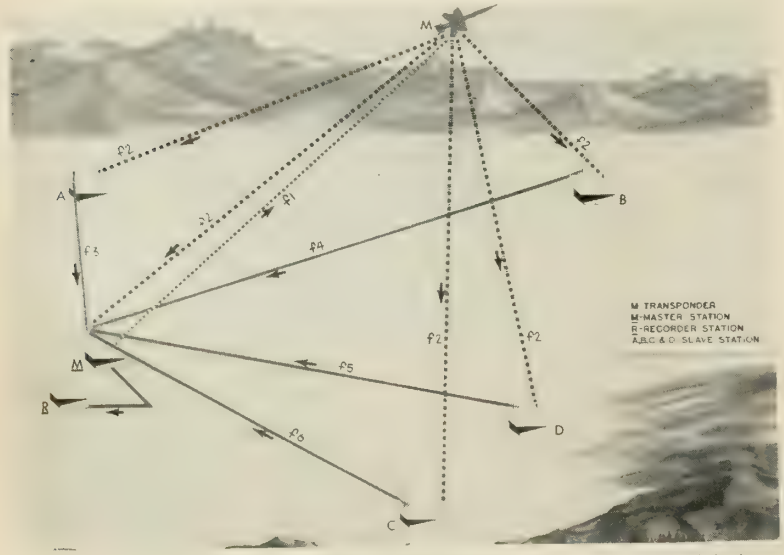
Combinations of measurement methods are selected for applicability to different tests depending upon parameter accuracy, degree of automation and logistic needs.

What the trajectory systems provide is a time history of the missile flight path. This is in the form of space-position data with velocity and acceleration derivatives.

These data are used for post-flight analysis of missile performance, or for control of missile while in flight. Latter applications might be for real-time trajectory measurement for flight-safety control, miss-distance measurement, navigation when missile data sites are shipborne or airborne, or real-time systems that are part of a control loop.

Measurement of propagation time is done in three ways: pulse time, frequency measurement, phase measurement. Systems in the vehicle may be passive or active-passive requiring no transponder, or active requiring a transponder. Another (hybrid) system requires no transponder but uses an rf signal generated in the missile to operate a telemetry transmitter.

Ground systems may be of multi-station type where stations are distributed over a test range to give the required geometry, or a single-station which yields all measurements to obtain trajectory data.



Although categories of trajectory systems based either on geometry or measurement techniques are not distinctive, they may be arbitrarily divided in four groups: Doppler phase measurement; pulse time measurement; interferometer.

Present Systems

Some factors to be considered before a trajectory measurement system is selected are:

- Can the missile accommodate a transponder and antennas?
- What is the trajectory? Accuracy and resolution of systems are different for different trajectories.
- What is stability and accuracy of data derivatives? A system may produce medium-accuracy position data and high-accuracy velocity data or the reverse of this.
- Cost balance between expensive single-station systems and lower cost available multistation systems.
- Data transmission costs for multistation systems.
- Is real-time data needed or will rapid data-reduction techniques suit the need?
- What are the frequency requirements? Spectrum availability, interference and propagation problems must be met.

Two of the most common Doppler systems are DOVAP and TRIDOP. Known as "elliptical" systems, they use the principle of detection and integration of Doppler frequency shift resulting from missile velocity.

Radar triangulation pulse time system. Pulse-modulated carrier is frequency shifted in missile. This signal is again shifted by slave stations and sent to master station.

A high-stability rf signal is sent to the missile from a ground reference transmitter. The signal is received by a transponder in the missile and a number of ground based receivers.

In the missile the signal is doubled in frequency and retransmitted to the ground receivers. Comparison of the original and doubled signal gives a Doppler "beat." By integrating this signal a loop range representing distance from transmitter to vehicle and back to the receivers is obtained.

The loop range is a non-directional quantity and describes ellipsoids of revolution with the transmitter and receivers as foci of the ellipsoids. By solving for the intersection of three or more ellipsoids, space position of the missile is determined. By successively differentiating the position data, velocities and acceleration at different points are obtained.

There are other Doppler systems such as PARHOP, which uses no transponder but depends on reflection of a continuous wave signal. SPHEREHOP eliminates the transmitter-to-missile link by using a very stable oscillator in the missile. Reflection Doppler uses a single station to derive velocity data only.

Among the phase measurement systems are ROMOTAR, SECOR, and DORAN. Station configuration for these can be similar to DOVAP's. Geometry of the system may be elliptical or spheroidal. With these a group of ranging frequencies modulate an rf carrier sent from a master station. The signal is received in the missile and at ground receivers. In the missile, the rf carrier is offset in frequency and retransmitted. The frequencies received from the missile by the ground receivers are different in phase from those received by the master station.

Phase shift is proportional to changes in path length throughout the trajectory. Using four or five modulating frequencies, high precision, non-ambiguous readings may be obtained over long ranges.

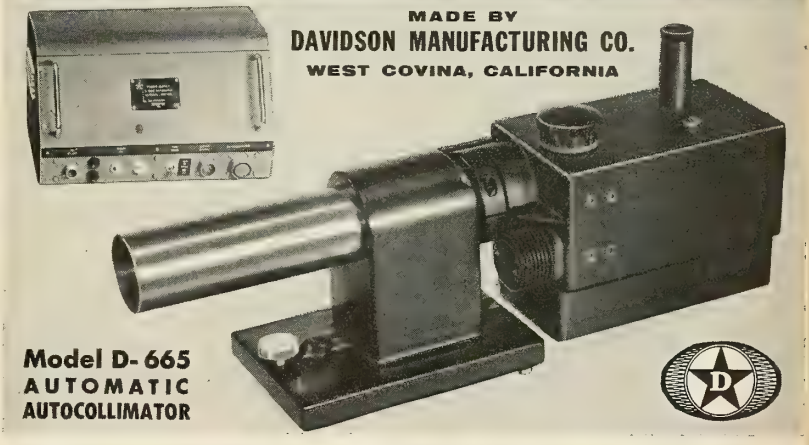
Another of the phase-measurement systems uses a transmitter and receiver at each ground station. Controlled sequencing of transmissions is used and each transmitter interrogates the missile in turn. Each station obtains a range measurement and missile position is determined from the system of spheroidal loop range data obtained.

Pulse time systems are basically applications of radar technique. They are based on transit time of a pulse from a ground transmitter and return. One of these is the radar triangulation MIRAN system.

With MIRAN a pulse-modulated carrier is sent to a missile. The missile receives it, shifts the frequency and retransmits the signal to slave receiving stations on the ground.

The slave stations offset the received frequency and beam the signal back to a master station. At the master station the times for transit of the pulse from the missile to each of the slave stations is measured. Missile position is obtained by solutions similar to previously mentioned systems.

Some of the electronic interferometer systems are MINITRACK, COTAR and EMA. MINITRACK will be used to track the satellite launched from the Project *Vanguard* vehicle. Such systems perform angular measurements by comparing phase of a signal received from a missile at two antennas mounted on a short baseline.



The phase difference is related to the direction cosine of the angle. To obtain high precision and ambiguity resolution, multiple antennas are used on short and long baselines. Also, by crossing baselines two direction cosines are found from which azimuth and elevation angles can be obtained.

If such a facility is combined with a means of range measurement of the Doppler or phase measurement type, the system becomes a single-station system. Sometimes two or more angle measurement stations are set up on a long baseline to permit triangulation for obtaining position, velocity and acceleration data.

The EMA system is not a trajectory measurements system but gives

OPTICAL
measurement of angles
AUTOMATICALLY

MADE BY
DAVIDSON MANUFACTURING CO.
WEST COVINA, CALIFORNIA

Model D-665
AUTOMATIC
AUTOCOLLIMATOR

Astounding advances recently made by science and industry have created a need for detection of extremely small angular errors of variations for purposes of measurement, alignment or control.

Davidson has developed this Model D-665 Electronic Autocollimator to make available to industry for the first time a truly fast, accurate and sensitive angular measuring instrument.

Due in part to inherent sensitivity of completely transistorized electronics, and in part to elimination of human errors which characterize use of standard autocollimators, the Model D-665 offers you a much higher increase in sensitivity and greatly decreased response time than you can find in other instruments.

Angular readings appear automatically on a calibrated dial, one revolution of which equals 10 seconds of arc.

On the same shaft as the dial, a potentiometer is mounted, across which operator may put up to 125 volts. A voltage proportional to the measured angle is then obtained between the slider and center tap.

Two jacks are provided, across which appear either a positive or negative voltage, depending upon which direction the reflector is misaligned. They will be useful primarily in problems of alignment, when the dial is held motionless.

Ability to quickly detect exceedingly small angular changes and present them in convenient electrical form makes a Davidson D-665 Automatic Autocollimator the obvious answer for a wide variety of applications, many of which were impossible before this time.

Circle No. 90 on Subscriber Service Card.

low-precision information so optical instruments may receive the vehicle being tested.

Future Systems

There are other systems available which, because of security, cannot be discussed. Others are under development. However, to get the utmost out of any system and to select one that will do a particular job, considerable system analysis is required before it goes into use.

According to Miller the trend in the past few years has been to specialization in error analysis of trajectory systems. This work is aimed at verifying measurement precision. These tests must often be dynamic, involving actual missile flights.

At this time the study of errors is directed to simplification of analysis by obtaining a mathematical method for describing the geometry of various systems. A mathematical approach will show which systems of geometry are best for exploitation.

After that, precision figures could be obtained for every conceivable technique. This would result in a tabulation of statistical figures for application to system selection.

This information would enable rapid selection of a particular geometric configuration to satisfy a given set of parameters established by the missile in question and reveal what must be learned about it.

Other problem areas that must be included in the new analytic tool that will become available are effects of ionospheric refraction, flame attenuation of electromagnetic radiation, ionization shields around high speed missiles and effects of atmospheric noise.

Interferometer system similar to MINITRACK, using two stations to measure phase difference at multiple antennas. Two-station system gives position, velocity, acceleration.

Another trend in this field is consideration of measurement system requirements at the time a missile is conceived. Specific provisions are being made in designs to include necessary instrumentation as part of the system design.

Miller predicts that we will ultimately have measurement systems in which trajectory, telemetry and real-time control are a single integrated system. ★

New high-speed polar relay

Completely reliable high-speed switching or keying in low-power or dry-circuit applications.

BILLIONS OF OPERATIONS: Designed for use in such equipment as air-to-ground telemetering, analog and digital computers, aircraft or missile control, and carrier-current switching, Bristol's® Syncroverter® relay is available to meet a wide variety of requirements, including the typical data given below. Write for complete information. The Bristol Company, 173 Bristol Road, Waterbury 20, Conn. 6.41

Covered by patents

TYPICAL CHARACTERISTICS

Temperature range: —55°C to 100°C. . . . **Operating shock:** 30G; 11 milliseconds duration. . . . **Vibration (10-55 cps, see below, mounting):** 10G. . . . **Contact ratings:** up to 35v, 45 microamperes. . . . **Stray contact capacitance:** less than 15 mmfd. . . . **Pull-in time (including bounce):** as low as 200 microseconds. . . . **Drop-out time:** 300 microseconds. . . . **Life:** Billions of operations. . . . **Mounting:** Octal tube socket; others available, including types for vibration to 2000 cps.

Special dust-free labs required in the development of air-bearing gyros

air-lubricated gyros

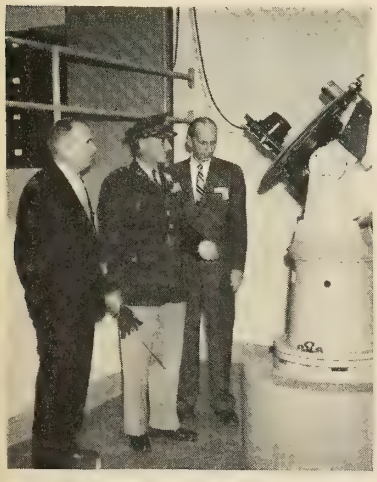
By Norman L. Baker

THE DEVELOPMENT of the guided missile has opened many new fields of engineering. New approaches to the engineering field have led to the rapid growth of new techniques. This applies particularly to the technology associated with ballistic-missile guidance, which is spearheaded by the Missile Development Division of Ford Instrument Co.

This group is currently engaged in work on two missile programs for the Army Ballistic Missile Agency at Redstone Arsenal. The first of these programs involves the *Redstone* missile and the other, the *Jupiter* missile.

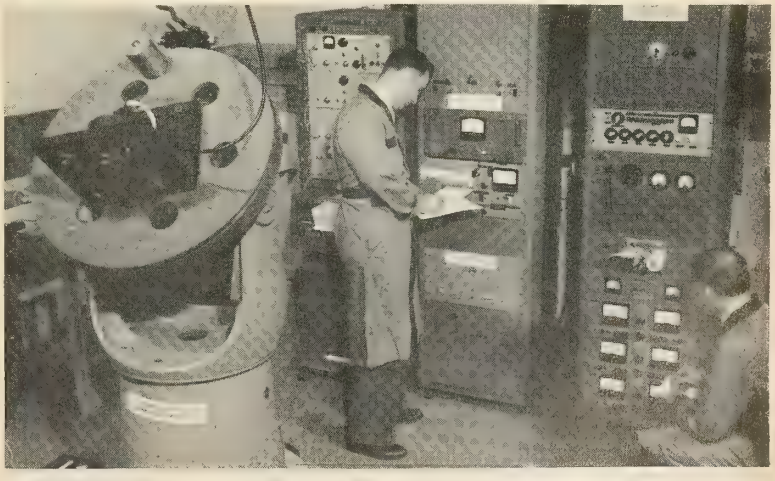
In nearly five years of engineering and manufacturing effort, a highly successful product-improvement program on missile guidance and control components has been achieved, in particular on the Redstone Arsenal-developed air-bearing stabilizing gyros and air-bearing gyro accelerometers. These air-bearing devices are major components of the stabilized platform used as the nucleus of the navigation system of the *Redstone* missile.

The air-bearing gyro and air-bearing gyro accelerometer were developed by Redstone Arsenal and adapted for production by the FICo, the only company in the U. S. that manufactures such a gyro.



At the present time, work on the *Redstone* missile program includes an evaluation and improvement program aimed at determining the extent to which the guidance and control system components will withstand the rigors of military storage, handling and firing. Components are subjected to the most severe climatic and environmental conditions they will face during storage, handling and firing by the Army's own personnel. Invariably, these environmental tests demonstrate weaknesses in design which can only be detected by semidestructive environmental testing.

Early in 1956 FICo launched the second of its ballistic missile programs. The character of the *Jupiter* engineering effort now in progress differs markedly from the current *Redstone* missile work. While the *Redstone* project has progressed to the point where existing designs are continually improved and reimproved, the *Jupiter* work involves the formulation of the first designs of experimental missile hardware. However, much of the theory underlying *Redstone* guidance, and much of the experience gained in developing guidance and control equipment for the *Redstone*, is directly applicable to the *Jupiter* missile work



A modern gyro-test lab was set up to evaluate and measure the accuracy of the ultrasensitive air-bearing gyroscopes used in the *Redstone* and *Jupiter* guidance systems. Experience has shown that even the smallest dust particle could create an unbelievable amount of friction torque in the presence of ultraprecision gyroscopes. With this uppermost in the minds of the planners, the lab was designed to be one of the cleanest and most dustproof in existence.

The completely enclosed laboratory is windowless and has a minimum of horizontal surfaces. Extra plaster was applied to areas between ceiling and walls to round off what normally would have become right-angled dust-collecting spaces. All wires are hidden within the walls and receptacles and fixtures are flush with the walls. Floors, ceiling and walls are smooth and clean. A specially-treated dust-absorbent mat covers the area between the vestibule and the outside door.

In the vestibule are lockers for changing clothes. Employes working in the gyro lab must remove their shoes before entering through the heavy, win-

Larry Brown, FICo, ABM9 Gen. Medaris and Raymond Jahn, Pres. FICo, visit gyro lab.

Engineers examine air-bearing gyro drift data that has been recorded by drift-rate measurement apparatus. Equipment will measure angular drift rates of one revolution in 40 years.

Engineer installs an air-bearing gyro on sensitive equatorial test stand in FICo test lab.

dowless double doors opening into the main work area. They must wear special, lint-free white coats.

Sheet linoleum was selected for floor covering, since tile and many other materials would have been broken up by dust-collecting crevices. A dustproof public-address system is housed in the ceiling for convenient interlab communication. This eliminates any unnecessary traffic through the lab.

Eating, drinking and smoking in the work area are taboo. No "unnecessary" tools or equipment may be brought into the lab, mainly to keep out additional potential dust carriers. Consideration is being given to the drilling of a periscope-type device through the outside wall so the night watchman can inspect the area without danger of carrying dust inside the lab.

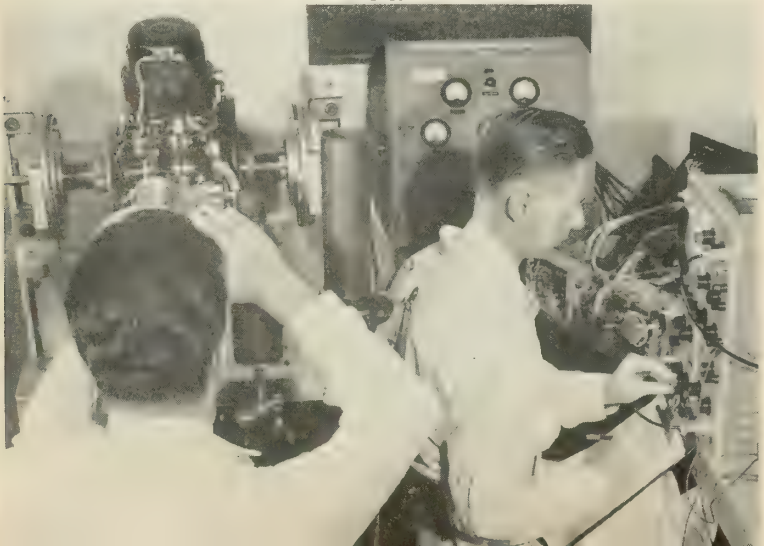
Daily all surfaces, such as desk and bench tops, are vacuum-cleaned, using a brush attachment. Plastic waste baskets of the dustproof, washable type are used and are emptied outside. Glass surfaces are cleaned with a moistened cellulose sponge rather than with a dust cloth or broom. All floors are cleaned with cellulose mops.

All walls and ceiling areas of both main laboratory and vestibule are vacuum-cleaned. They are also cleaned with a cellulose sponge using warm water and a mild detergent. Every effort is made to prevent the water from dripping. The floor is waxed with a cellulose-sponge attachment using a special dust-resistant mixture.

Porters wear white coats, white gloves and moccasins over their shoes when working in this area. But no gloves are worn during any washing procedure. Equipment belonging to the lab porters is thoroughly cleaned after use before re-storing in special lockers. Periodically the inside of the duct work for the air conditioning and heating systems are vacuum-cleaned.

Outside experts were called in to further insure that the area be free of dust. The finest available separately controlled air conditioning and heating plants were installed in a room directly below the lab. The air conditioning features a special-type filter often used in Atomic Energy Commission work. It is believed to be the most completely dust-free filter yet made.

An air compressor was purchased to provide the gyro lab with clean, dry, filtered air free of contamination and oil vapors. This is the same type of air compressor used to supply air for hospitals. A special air dryer has also been installed.



Temperature and humidity controls were built into the walls to provide complete control of temperature and humidity for the extremely sensitive gyroscopes being tested.

The lab was located in an area of the plant where building vibrations from any cause were minimized. Simple tests with a pool of mercury and a vibration meter helped determine the most vibration-free site. The area also had to be soundproofed to reduce the noise coming from high-speed rotating machinery used to test the gyros.

The Coast and Geodetic Survey, which specializes in precision mapping of the U. S., was called in to establish a line between two bench marks. From that line the engineers were able to orient a rotating test stand so its axis was parallel to the earth's axis.

FICo expects this lab to play an increasingly vital role in the current era of guided missiles and the not-too-far-off era of space travel. ★

Measurement of drift rate of the air-bearing gyros in the REDSTONE's guidance system.

thermocouple application for ballistic missiles

Temperature measurements are accomplished by thermocouples in Redstone and in Jupiter

By Charles T. N. Paludan
Army Ballistic Missile Agency

THE MOST RELIABLE temperature measurements that can be made on a ballistic missile, from a mechanical standpoint, involve the use of thermocouples. A thermocouple measuring junction can easily be located at practically any point within or on the missile. This is not always true in the case of resistance thermometers, thermistors, gas, vapor pressure or bimetallic thermometers.

In many cases a thermocouple installation may be exceedingly rugged. At the present state of the art the insulation resistance problem gives the thermocouple a decided advantage over resistance-type measurements at high temperatures.

Three primary problems are associated with thermocouple measurements: (1) low output, (2) lead resistance and resistance change, and (3) the reference junction temperature.

The low output problem can be solved by means of a stable, high-gain DC amplifier of the magnetic, chopper, or transistor type. As most thermocouple materials have a high resistivity and a high temperature coefficient of resistance, large errors are possible if long leads and severe environmental temperatures are involved.

This error could be minimized by avoiding long leads of thermocouple material, changing over to low-resistance copper wires for the major portion of the distance. This could be done by placing the reference junction near the measuring junction.

The reference junction temperature must be determined in order to evaluate the output of a thermocouple system in terms of measuring junction temperature. This is commonly done in the laboratory by immersing the reference junction in an ice bath or, for less precise work, by determining the reference junction temperature by means of a mercury-in-glass thermometer.

Industrial and missile applications, involving the use of meters or recorders, make an automatic or semiautomatic correction for ambient temperature changes by means of a bimetallic device, a thermistor, a resistance thermometer, or a moving vane. Slide-wire potentiometers are often equipped with similar devices.

Another method is to maintain a fixed, higher-than-ambient temperature within a small oven. A much simplified but far less elegant method would be to imbed the reference junction in some material of high heat capacity, measure the temperature with a mercury-in-glass thermometer, and assume no change for a given length of time.

Oven devices have been used extensively and are available commercially from a number of manufacturers. One such device, developed for the Army Ordnance Corps by members of the Chrysler Corporation's missile branch, has been used for a number of temperature measurements in the *Redstone* missile (Fig. 4).

This device, although successful, did not eliminate the problems of long thermocouple leads, the need for thermocouple material connectors, and the inability to read temperatures below the oven's set temperature. Furthermore, the oven acted as a heat source which was sometimes troublesome when it was operated near temperature-sensitive equipment.

In order to prove that all temperature-measuring equipment was func-

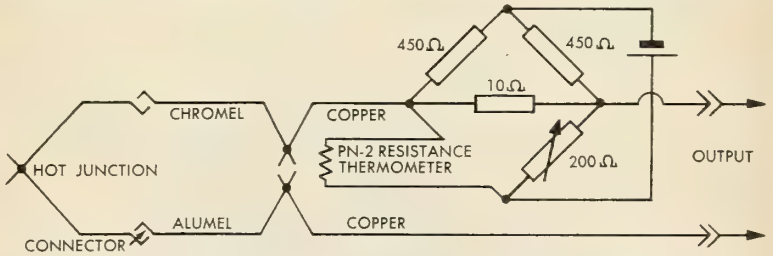


Fig. 1—Circuit diagram of first reference junction system for the REDSTONE missile. The ambient-temperature-sensing thermometer dictates proper correction into the system.

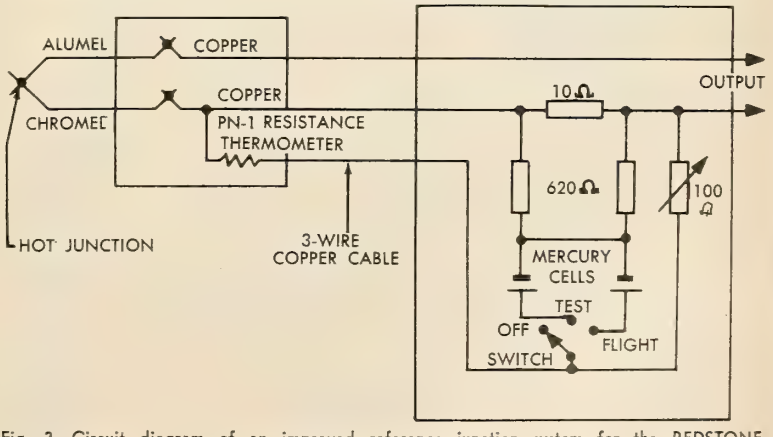

Fig. 2—Circuit diagram of an improved reference junction system for the REDSTONE. Dependability of the system is largely a function of the stability of the mercury cell.

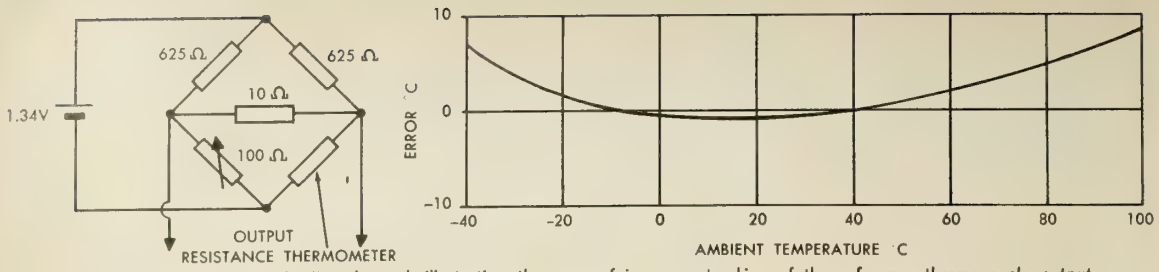

Fig. 3—Circuit diagram of "zone box" and graph illustrating the error of improper tracking of the reference thermocouple output.

tioning properly before a missile launching, it was necessary to read the ambient temperature which was usually on the order of 25°C. Many of the measuring points were inaccessible for external heating.

An actual ice bath reference would be impractical for missile use because of the difficulty in servicing it. Furthermore, it would not eliminate the extension lead problem of the scattered measuring points. A series thermistor compensator would be difficult to devise because the impedance of the amplifier system would vary for different ranges of measurement. A series thermistor device would still give zero output at ambient temperature, an undesirable condition.

Basically, the reference junction problem is one of knowing the reference junction temperature. As this knowledge is useful only as a correction, it would be sufficient if the correction were made directly in the measuring system.

If the reference junction is to be at ambient temperature with no resort to ice or oven, and is to be located near the measuring junction, the ambient temperature must be sensed at that point. The ambient-temperature-sensing organ would then dictate the proper correction into the system. As the required correction is electrical, a resistance-changing sensing organ is needed. Inexpensive resistance thermometers are available which will serve the purpose.

Figs. 1 and 2 are circuit diagrams and essential parts of a system meeting the requirements just outlined. Fig 1 depicts a system which has been used for several hundred measurements in the *Redstone* missile. Fig. 2 is an improved version for use in the *Redstone*.

As can be seen in the circuit diagrams, the resistance thermometer senses the reference junction temperature, operates into a deflection-type wheatstone bridge which draws power from a mercury cell, and applies a correction across a ten-ohm load resistor which is in series with the overall thermocouple circuit. The error introduced by the series ten-ohm resistor will be negligible if the impedance of the amplifier system is sufficiently high. At any rate, it can be calibrated out.

The dependability of the system is largely a function of the stability of the mercury cell. It is desirable to use a fresh cell for the missile's flight, because check-out procedures at the launching site may have exhausted the energy of the original cell.

In most cases the measuring junction is in direct contact with some metallic part of the missile. This makes the junctions electrically common. For this reason a separate compensating system and mercury cell are required for each measurement.

The original equipment shown in Fig. 5 required mercury cell servicing at each installation point. In some cases this would be an advantage; however, the complexity of a large missile system such as *Redstone* or *Jupiter* makes the task of battery replacement rather formidable. For that reason the new system (Fig. 2), with its centralized batteries was evolved. In either case the individual cell lifetime would be several weeks.

Utilizing an adjustment potentiometer, the reference setting may be varied so as to give artificial reference temperatures at levels other than 0° C. In that way it is possible to make thermocouple temperature measurements with elevated or depressed temperature levels of zero electrical output. For example, a measurement might have a span from −50°C to +500°C, in which case the thermocouple com-

Unsurpassed for accuracy and dependability, Whittaker Gyros are able to shrug off the effects of shock, acceleration, vibration, heat or cold.

THE REASON? For all the foregoing conditions, Whittaker Gyros have been *100% tested!* Rigid quality control has resulted in continued customer satisfaction since 1946.

And because Whittaker uses nickel alloys such as a monel for frames and gimbals, added strength is gained with little increase in weight.

Whittaker engineers and technicians have worked together as a team for more than a decade. This background and experience insures meeting exact specifications the *first* time.

Whittaker Gyro

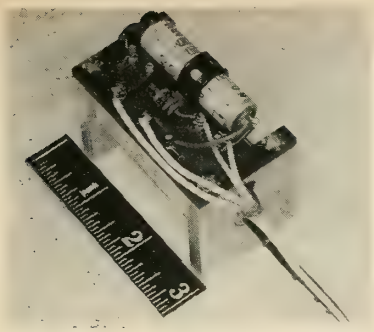

Fig. 4—Oven device for temperature check.

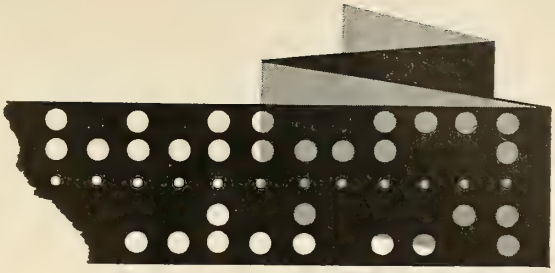
Fig. 5—REDSTONE reference junction system.



pensator system would have zero millivolts output at −50°C.

The accuracy of the system presented here depends on the ability of the resistance thermometer-bridge system output to track the output of the actual reference junction thermocouple. As the load resistor of the bridge is in series with the output of the system, it must be kept small—about ten ohms.

The voltage supply to the bridge is fixed by the potential of a single mercury cell. Series cells are ruled out for reasons of reliability. In order to obtain sufficient output from the bridge, the ratio of the high to low resistance arms of the bridge is somewhat small with the result that the bridge output is unlinear. Therefore, the compensator circuit does not track the reference thermocouple output perfectly. However, the tracking is sufficiently close for most practical purposes over a considerable span of ambient temperature. Fig. 3 illustrates the error resulting from improper tracking.

The system described has been given the name "zone box." The name was suggested by the fact that the unit includes a zone of equal temperature for the reference junction thermocouple and the resistance thermometer.

Development work on the zone box was done in the RF, Telemetering and Measuring Section of the Guidance and Control Laboratory, Army Ballistic Missile Agency, Redstone Arsenal. ★

computers

Northrop needs computing analysts, qualified either by experience or education, to work in their ever-expanding Computer Center at Hawthorne, in Southern California. If you are qualified, there is an interesting position as well as a bright future for you at Northrop.

Applied mathematicians and engineers are needed as computing analysts for assignment to Northrop's analogue computing facility, as well as their enlarged digital electronic computer department which provides unparalleled service in the practical solution of complex engineering problems.

Your assignments will be fresh and stimulating, and you will have frequent opportunities to advance in your field. Besides an excellent salary, you will receive company-paid benefits that are unexcelled in the entire aircraft industry. Your colleagues will be the brilliant engineers who developed the USAF-Snark SM-62 intercontinental guided missile and the new USAF-Northrop T-38 supersonic twin-jet trainer. These men are congenial and helpful, and will respect your ability and individuality just as Northrop expects them to do. And you and your family will fully enjoy Southern California's many attractions and its delightful all-year climate.

If you qualify for any phase of computer research, design, or application, we invite you to contact the Manager of Engineering Industrial Relations, Northrop Division, Northrop Aircraft, Inc., ORegon 8-9111, Ext. 1893, or write to: 1041 East Broadway, Dept. 4600 R, Hawthorne, Calif.

BUILDERS OF THE FIRST INTERCONTINENTAL GUIDED MISSILE

5-A-143

Long Range Telemetering Transmitter

The demand for extra radiating power near the terminal phase of missile flights has led to the development of a small transistorized 200-watt transmitter with an extended range.

It is in the terminal phase of flight that many unpredictable problems occur, and until now this has been the very region in which background noise has blacked out the weakening telemetered signal. Stepping up transmission power will override background noise and extend transmission range considerably beyond line-of-sight limits imposed by present transmission equipment.

Transistorized to the practical limits of the state of the art, the new 200-watt PM transmitter was developed by the apparatus division of Texas Instruments Inc. It increases substantially the effective range of FM FM telemetering. The new equipment is complete in a single unit and requires no amplification of the output. It is small and lighter than currently available 50-watt transmitters for similar duty, occupying only 67 cubic inches.

The new units transmit in the 215-235 mc range with frequency stability of plus or minus 0.01 per cent up to 71°C. Higher frequencies are possible with only minor modifications. The basic unit can also be modified to operate at power outputs as low as 25 watts. Operation at 200 watts requires 12 cfm external cooling air.

Thermal control

Integral "heat sink" provisions are ideally suited to missile requirements, stretching out the transmitter's operation during periods of rapid build-up—for example, during re-entry into the atmosphere. High-temperature silicon transistors are used in the oscillator, phase modulator, video amplifier, and frequency doubler circuits. The output stage utilizes a stacked ceramic tetrode with considerable excess capacity, and tubes are also used as drivers and multipliers.

Texas Instruments is also supplying components for the instrumentation package of the *Far Side* high-altitude test program now underway.

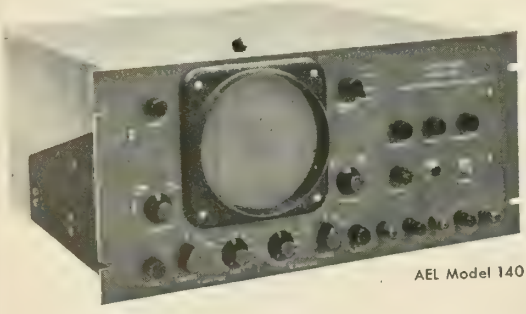
Plug-in Telemetry Units Explored by Seeburg

Telemetry systems with removable circuits that may be used in varying combinations to provide telemetering equipment for any missile test program are being developed by J. P. Seeburg division of Fort Pitt Industries, Inc.

Seeburg, developing the basic "building-block" components with its own funds, feels that the advantages of such a flexible telemetry system are almost unlimited. The individual plug-in circuits would also allow changing of functions within a missile's telemetry.

Radio Spectrum Study Approved by EIA Board

A cooperative long-range study of the radio spectrum, covering both military and civilian uses of frequencies, was approved in principle by the board of directors of the Electronic Industries Association at the conclusion of a three-day EIA conference in Los Angeles.



The proposal for the study emphasized that the radio spectrum is one of the most valuable national resources and that its full value can be realized only by means of frequency allocations based on comprehensive technical information.

Big Antennas Replaceable With Smaller Units

Two scientists of Bendix Aviation Corp.'s systems division have announced a technique whereby extremely large and complicated antenna structures can be replaced by much smaller and simpler structures.

The scientists, Dr. Winston E. Kock and Dr. Jack L. Stone, described an example where the beam of a parabolic dish 10 feet in diameter was duplicated by three small wide-band receivers arranged in an equilateral triangle, six feet on a side.

The technique is applicable to sonar underwater sound systems, radio astronomy and other forms of radio and radar.

AEL Model 140

Display Oscilloscope

A display unit for use as a dynamic indicator with ANALOG COMPUTERS, CURVE and FUNCTION GENERATORS, etc. The "140" is designed with very low values of hum, noise and drift specifically to enable quantitative measurements. No internal sweeps are provided.

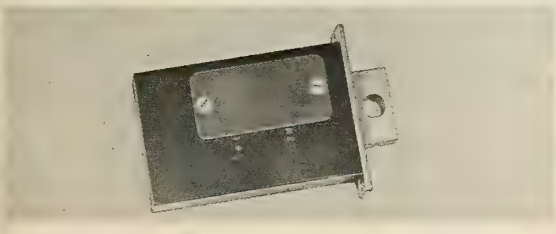
New Universal Temperature Measuring System

Rugged and reliable – extends use of thermocouples, eliminates icebath and oven references



Simplified system accommodates all three gauge types. Magnetic-amplifier "heart" makes possible low-span thermocouple measurements up to 2000°C. Developed for a major missile program, system is fully flight-tested. Offers industrial uses, too.

Use of thermocouples as sensing elements boosts measurement level from 900°C to a new maximum of 2000°C. Characteristic ruggedness of thermocouples also increases system reliability. Thermistors or resistance thermometers may also be used as system requires.

Compact, inexpensive "zone box" (part no. 91-101-0) does away with icebaths and ovens by simulating exact reference temperatures electrically. Box mounts near thermocouple, thus eliminating long leads. It withstands extreme environments without losing accuracy. Since each thermocouple feeds into its own zone box, referencing is decentralized, system reliability and flexibility are further increased.

Zone box adapter (part no. 91-102-0) permits easy, precise adjustment of thermocouple reference to point desired. Adapter suitable for operation into low- or high-impedance instrumentation. Both adapter and zone box are manufactured by Magnetic Research Corporation to ABMA specifications.

Micromag MM 423 low-level dc magnetic amplifier is the virtually indestructible heart of the system. It is the stability of this unit that makes possible the use of thermocouples under severe operating conditions. Amplifier drift is less than .1% over 2000 hours. Voltage gain of 500 simplifies small-span measurements with any of the three gauge types. Unit is temperature compensated for high gain stability. Used with or without zone box and adapter, the Micromag ups reliability of temperature and strain measuring systems.

SPECIFICATIONS OF MICROMAG* MM 423 LOW-LEVEL MAGNETIC DC AMPLIFIER

Voltage Gain:	500
Input Resistance:	200 ohms
Drift:	Less than .1% over 2000 hours
Output:	0-5 VDC into 100 kilo-ohm load
Response Time:	80 milliseconds
Compensated Temp. Range:	0 to 60°C (can be extended to 85° upon request)
Environment:	—55° to 105°C
Power Source:	105-125 VAC, 400 CPS
Vibration, etc.:	Designed to meet MIL-E-5272 specs.
Volume:	Less than 7 cubic inches
Weight:	11 ounces

MM 424 Micromag Low-Level Magnetic DC Ampifier Same model as above. In addition, it provides its own DC voltage regulated to .1% to replace mercury batteries in Zone Box system or power bridge type measuring devices.

MMO 528 Micromag Low-Level Magnetic DC Amplifier Same as Model MM 423 above, but powered from unregulated 28 VDC system.

Write or telephone for technical information on MRC temperature-measuring systems and components. Our Engineering Department will be glad to discuss your special needs.

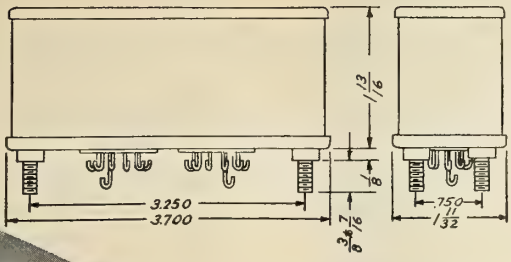
KG SERIES RELAY



The new KG magnetic latch relay was designed by P&B engineers at the insistence of leading aircraft and missile manufacturers and their suppliers of control systems. A permanent magnet which locks the armature into position is the secret of the KG's dramatically high resistance to shock and vibration.

In addition to withstanding 30g vibration from 6 to 2000 cps, tests show the contacts will open for no more than 80 microseconds during 100g shock.

Armature transfer from one set of th 6PDT contacts to another can be made approximately 12 milliseconds with only 2 watts at nominal voltage. The KG is rate for ambient temperatures from −65°C t +125°C.

The KG, together with other relays in th P&B "Star Series", has vastly increased th realm of relay reliability for critical applic tions demanding positive action of all com ponents. Write or wire today for comple technical data.

POTTER & BRUMFIELD, INC., PRINCETON, INDIANA—SUBSIDIARY OF AMERICAN MACHINE & FOUNDRY COMPAN

STAR SERIES

KG RELAY

DESIGNATION: KG23D8H

GENERAL: Insulating Materials: Teflon, glass and ceramic.
Insulation Resistance: 100 megohms min.
Breakdown Voltage: 500 V. RMS.
Shock: 100g where contact openings less than 80 microseconds may be permitted.
Vibration: 30g 5 to 2000 cycles.
Ambient Temperature: —65°C to +125°C.
Weight: 13 ozs.
Pull-in-Speed: 12 MS using 310 ohm coil at 24 V. DC. (25°C).
Terminals: Two 11 pin multiple solder headers with hook ends for 3 #20/AWG wires.
Enclosures: Hermetically sealed only.
Dimensions: 1-11/32 x 3.700 x 1-13/16 (See drawing for width, etc.)
CONTACTS: Arrangements: 6 pole double throw.
Load: Dry circuit to 3 amps, 115 V. AC, resistive. 5 amps, 28 V. DC, resistive.
COIL: Power: 2.0 watts at Nominal Voltage.
Duty: Either coil may be left energized without damage to the relay.
Insulation: Teflon tape.
MOUNTINGS: Four ⅜ inch #8-32 studs on 3¼ x ¾ inch centers.

COIL DATA:(EACH COIL)

Voltage:	6 V. DC	12 V. DC	24 V. DC	48 V. DC	110 V. DC
Resistance: ±10% @ 25°C	14 ohms	55 ohms	310 ohms	835 ohms	5500 ohms

industry briefs

Northrop Creates Nortronics Division

Northrop Aircraft, Inc., has created a new division, to be called Nortronics, which will handle the company's operations in the design, development and manufacture of electronic, electro-mechanical and opto-mechanical products and components.

The establishment of the new line operating division will enable the company to collect its work in these fields under a central detailed management. In creating Nortronics, the company elected Dr. William F. Balhaus a vice president of Northrop Aircraft, Inc., and assigned him duties as general manager of the Nortronics Division.

Babcock Opens Facility To Consolidate Plants

Babcock Radio Engineering, Inc., has opened a new facility at Costa Mesa, Calif. The 25,000-sq. ft. in plant area will allow consolidation of all the company's divisions in a central location.

Babcock is producing drone guidance and electronic ground support equipment for Beech and Radioplane drones and also for several leading missile programs.

Micronics Gets R&D Contracts

Three research and development contracts covering guided missile components have been awarded to the Micronics division of Elgin National Watch Co. The new contracts total approximately $500,000 and have been assigned to the division's West Coast R&D laboratories at Burbank.

Atomichron Contract Awarded to National

National Co., Inc., communications equipment and atomic clock manufacturer, has received a $609,525 contract from the Army Signal Supply Agency for development of military-type atomichrons. The device is used for super-accurate timing involving missile guidance.

Era Engineering Gets Development Contract

Era Engineering, Inc. has signed a contract with Douglas Aircraft Co. for development of an in-flight instrument to measure thickness of a material sample. The material erosion rate instrument is transistorized and withstands high acceleration loads.

complete electronic and mechanical assemblies

Encompassed in the scope of Erco's manufacturing operations are standard and custom-designed electronic and mechanical assemblies.

Long experience in the sheet metal and electronic industries has made Erco expert in both fields of endeavor. Illustrated above are two custom-built racks complete with electronic assembly ready for insertion into a trailerized* computer. These units are indicative of the precision electronic assembly and intricate metal working carried on at Erco.

You'll find that it is economical to consult Erco for the design and fabrication of complete electronic and mechanical assemblies. Erco offers you two major advantages as an electronic and mechanical subcontractor — advanced engineering experience and talent that has solved thousands of assembly problems and — one-quarter million square feet of manufacturing facilities concentrated under one roof.

Send Erco an outline of your problems in these fields or write today Dept. MS, Riverdale, Md., for more details. They are given in the brochure "Erco — Production Facilities."

*Erco also built the trailer.

glossarifery

As in other arts and sciences, the field of instrumentation and automation, in growing, has developed its own vocabulary. As a public service, and in an effort to promote communication with the outside world, we set forth below definitions of the most commonly used terms.

AIRFRAME: Ambiguous terminology. May mean either a frame constructed around a body of air, or a body of air surrounding something.

ALCLAD: Entirely clothed.

BASE METAL: A term used by makers of aluminum products in referring to stainless steel and vice versa.

BLUEPRINT: A melancholy reproduction.

BREEDER REACTOR: Two rabbits of opposite sex.

BINDING ENERGY: Energy required to tie up a package.

CHAIN REACTION: Longitudinal waves in a light chain when one end is vibrated.

CHAPERONE: Force action on a couple to maintain it in a state of equilibrium.

CHARACTERISTIC CURVES: Easiest way to distinguish between a steward and a stewardess.

CHIEF ENGINEER: A person totally devoid of all engineering knowledge who married the boss' daughter.

CLOUD CHAMBER: A bedroom with clouds.

COSMIC RAY: A ray of powder, rouge and lipstick.

CYCLOTRON: Electron on a bicycle.

ELECTRON: A man up for election.

ENGINEER: One who is educated in the art of developing new and different ways of making the same mistakes.

FAHRENHEIT: A system of measuring vertical height above the earth's surface. One Fahren equals 0.53959 nautical miles.

FISSION: Drowning worms on the end of a stick.

FITTING FACTOR: A process used in structural analysis whereby a factor is manipulated so as to fit a particular requirement.

FRESHMAN ENGINEER: A young man who knows why a strapless gown is held up but doesn't yet know how.

HYDROGEN: An alcoholic beverage consisting of water and gin.

ISOTOPE: Ski area covered with ice.

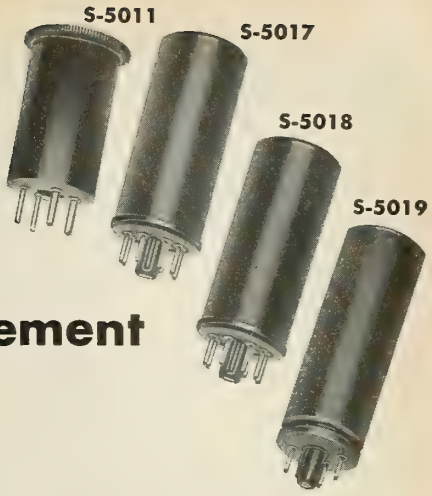
K-ELECTRON CAPTURE: Russian electron in captivity.

MESON: My son (colloquial).
NUCLEI: A recent lie.
OHMETER: One who eats ohms.
OXIDE: The hide of an ox.
PILE: Big heap.
PHOTON: A man who takes pictures.
PLANCK'S CONSTANT: The amount lumber is reduced from given dimensions when purchased at a sawmill.
POSITION: A man who is always right.
QUANTUM: A large sum of Wamptum.
RADIATION: Johnnie Ray's cousin.
REACTOR: An actor who takes part when an old play is produced.
REYNOLD'S NUMBER: 92-71941.
RADIOACTIVITY: A function with the use of a radio.
ROENTGEN UNIT: Unit price of a gun when rented.
SLIDE RULE: A baseball regulation.
TELEVISION: An improvement over radio. Now you cannot only hear static, you can see it, too.
THEORY OF RELATIVITY: A scheme for getting rid of your mother-in-law.
WOMEN'S TEARS: The first successful fluid drive.

Reprinted from ISA (Cleveland Section) Bulletin, Vol. 8, No. 1, Sept. 57.

RELIABILITY DEPARTMENT HEAD

To assume responsibility of organizing and establishing a department which will conduct reliability evaluation studies of advanced liquid propulsion systems.



Previous rocket experience desirable but not necessary. Should have thorough grounding in techniques of reliability analysis coupled with supervisory ability.

Located near Sacramento, California, the area offers a combination of excellent climate and recreational facilities.

Full Wave SILICON Tube Replacement RECTIFIERS

Where dependability and ruggedness are a "must," Full Wave Silicon Tube Replacement Rectifiers will solve your problems. One of the four standard types described below will meet the requirements of your application.

S-5011
1N1150

Maximum Rating:
Peak Inverse Voltage per Section ..... 1600 Volts Max.
Peak Rectifier Current per Section ..... 8000 MA Max.
DC Output Current ..... 750 MA Max.
Ambient Temperature ..... 100°C Max.

Dimensions:
A—1-1/2" O.D. B—2-1/4" C—2-27/32"
Four Pin Base
Replacement for Types 80, 82, 83, 83V, 5Z3

S-5017
1N1237

Maximum Rating:
Peak Inverse Voltage per Section ..... 1600 Volts Max.
Peak Rectifier Current per Section ..... 8000 MA Max.
DC Output Current ..... 750 MA Max.
Ambient Temperature ..... 100°C Max.

Dimensions:
A—1-3/16" O.D. B—2-19/32" C—3-5/32"
Octal base
Replacement for Types 0Z4, 5X4, 5Y4, 6AX5, 6X5

S-5018
1N1238

Maximum Ratings:
Peak Inverse Voltage per Section ..... 1600 Volts Max.
Peak Rectifier Current per Section ..... 8000 MA Max.
DC Output Current ..... 750 MA Max.
Ambient Temperature ..... 100°C Max.

Dimensions:
A—1-3/16" O.D. B—2-19/32" C—3-5/32"
Octal base
Replacement for Types 5AU4, 5AW4, 5AZ4, 5T4, 5U4, 5V4, 5W4, 5Y3, 5Z4

S-5019
1N1239

Maximum Ratings:
Peak Inverse Voltage per Section ..... 2800 Volts Max.
Peak Rectifier Current per Section ..... 5000 MA Max.
DC Output Current ..... 500 MA Max.
Ambient Temperature ..... 100°C Max.

Dimensions:
A—1-5/16" O.D. B—3-3/4" C—4-5/16"
Octal Base
Replacement for Type 5R4

Send for data sheets on any of the above types.

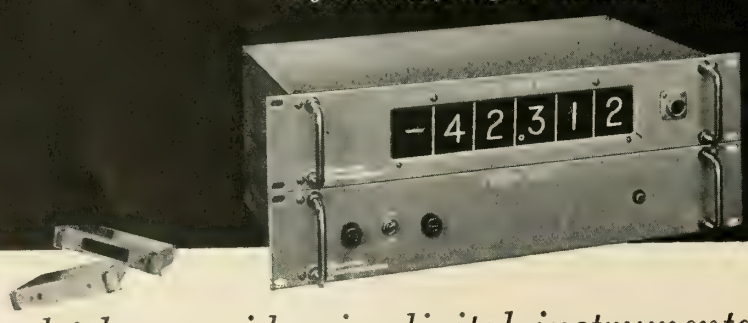
Precision instruments for automatically measuring DC, AC-DC, Ohms and DC-AC ratios constructed from basic modules.

For example:



Combine the Universal Power Module

with the DC Switch Module

to get an 0.01% Digital Voltmeter

a completely new idea in digital instrumentation!

Now from five basic E-I modules, almost any combination of instruments can be assembled for precision, digital measurement of DC, AC-DC, Ohms and AC-DC Ratios. The basic E-I modules never become obsolete. As needs change, simply regroup or add new modules. This new modular concept provides maximum versatility and enables equipment to be kept current at minimum cost and engineering.

New engineering specification and other features have been incorporated into the basic modules from the experience of over 2,500 digital instruments in the field. Where applicable, all circuits have been fully transistorized to provide increased reliability, low power consumption, low heat dissipation and to eliminate radio noise and line transients.

New catalog sheets *give the complete story of this newest advance in digital instrumentation and complete specifications on all modules. Write for your set today.*

ELECTRO INSTRUMENTS INC. 3794 Rosecrans, San Diego, California

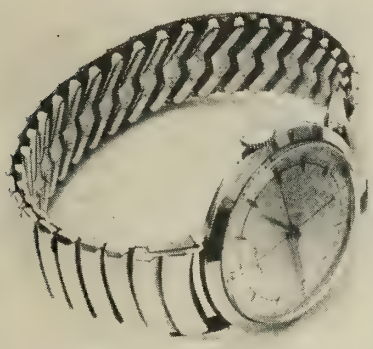
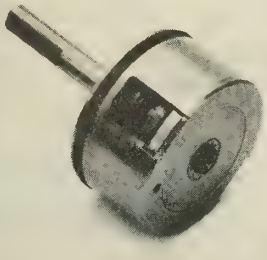
NEW MISSILE PRODUCTS

MINIATURE PUMP CARTRIDGE



Miniature vane pump cartridges with a delivery capacity of 1.04 gpm at 1000 psi and 10,000 rpm are in production at Vickers, Inc. The unit weighs 2.5 oz. and has an output of 0.6 hp. Overall diameter is slightly less than 1 1/8".

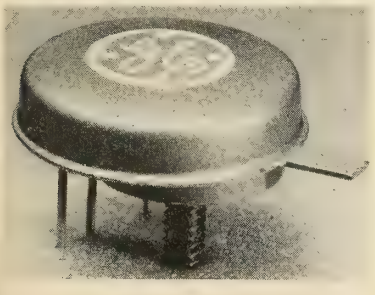


The pump may be supplied separately for incorporation into the user's housing either singly or stacked on a common shaft, or the manufacturer will furnish suitable housings. It can be manifolded with servo valves, miniature piston hydraulic motors and FHP electric motors.

The cartridge features hydraulic balance to eliminate pressure-induced bearing loads and the company feels that the performance figures currently cited will be extended. Shown with the cartridge is a standard wrist watch for comparison of size.

A minimum change in performance during the pump's life is expected by the company because optimum running clearances are automatically maintained by vanes and pressure plates that are self-compensating for wear. The cartridge incorporates many desirable features of the firm's larger models and overall construction is somewhat similar.

The unit is applicable for such operations as small radar or computer drives, electronic cooling, fuel pumps, missile skin cooling, flow dividers or pressure lubrication.

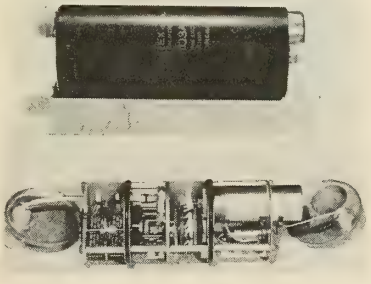


Circle No. 212 on Subscriber Service Card.

SILICON POWER TRANSISTOR

General Electric Co. has produced an 85-watt silicon power transistor said to have the highest power rating of any high-temperature transistor in the industry. The device will dissipate 85-watts at 25°C mounting base temperature and has a nominal collector saturation resistance of 2 ohms.

The component, designated the 2N-451, is produced by the vapor-diffusion process and is hermetically sealed in an all-welded case designed for mounting on an external heat sink.



Circle No. 210 on Subscriber Service Card.

BINARY TIME CODE GENERATOR

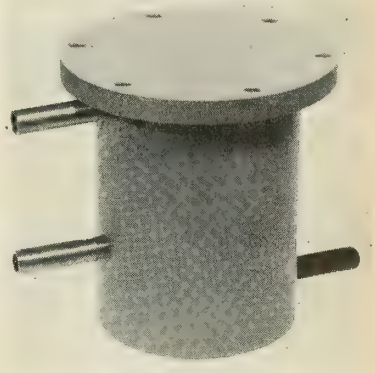
Giannini DATEX Model DC-103 produces a serial output of one synchronizing pulse followed by eight bits of binary coded DC timing signals per second. Total number of signals is 128.

Shock mounted, the unit withstands temperatures from —65°F to 170°F; linear acceleration of 75g along major axis; shock of 30g on any axis and vibration of 15g. It is completely enclosed in a hermetically sealed container and electrical connections are made through hermetically sealed plugs.

Circle No. 205 on Subscriber Service Card.

MIRROR GALVANOMETER

Hilger & Watts Ltd., of England, is producing a self-contained mirror galvanometer offering sensitivity as high as 2000 millimeters per microampere. The Hilger "Galvoscale," being handled in this country by Jarrell-Ash Co., features a brightly lit, built-in scale, fully legible under ordinary room illumination.



The magnified scale image moves below a stationary index line within a viewing hood and eliminates the visual effort, as well as the darkened room, required by other types of mirror galvanometer employing a traveling light spot and a stationary scale.

The instrument occupies table space of 12" x 21", but its scale length is equivalent to an optical lever nearly seven feet long. Both linear and logarithmic scales are available. Built-in shockproofing eliminates the need for special mountings.

Circle No. 209 on Subscriber Service Card.

ULTRASONIC TRANSDUCER

A high-efficiency ultrasonic transducer incorporating the most recent developments in magnetostriction transducer design has been developed by Massa Laboratories. The new device is said to be virtually indestructible and can operate continuously with 400 watts of power input with a conversion efficiency of 40%.

A sound pressure of 1 million dynes/cm² results in the vicinity of the transducer when radiating into open water with 100 electrical watts input to the structure. Cavitation is evident at this power level throughout about 80° total angle.

The polished stainless steel diaphragm has a radiating face 2 3/4" in diameter. Specifications: operating frequency—26 kc; impedance—150+j100 ohms; over-all dimensions—4 3/8" dia. x 4 7/8" long (6-ft. waterproof cable attached); water cooled, 5 gph for 30°F rise at 400 watts continuous input power; weight 6 lbs.

Circle No. 206 on Subscriber Service Card.

TELEMETERING SWITCH

A multichannel sampling switch designed for telemetering at altitudes up to 200,000 feet and at temperature from 125°C to —65°C has been developed by Applied Science Corp. of Princeton. It is available with from one to five

poles and with up to 60 contacts per pole at sampling speeds ranging from 0.5 to 30 RPS.

Various motor drives are offered and the speed regulation is ±3%. The switch withstands shocks of 150G bi-directional, 100G continuous acceleration bi-directional and a vibration of from 20 to 2000 cycles at 20G for ½ hour.

Circle No. 208 on Subscriber Service Card.

SUBMINIATURE COMPONENTS

New subminiature fixed glass capacitors are currently being produced by Corning Glass Works. Termed Corning WL capacitors, the radial lead units are being designed for printed circuit boards. Production is expected to begin in the near future.

No clamps are required because the high temperature soldered leads allow the capacitor to be connected directly to the breadboard. Both types of the component measure less than 0.1" thick, making them well suited for vertical mounting in small, high-rated circuits.

The units have a fixed temperature coefficient, high insulation resistance, low dielectric absorption and ability to operate under high humidity and temperature conditions. The capacitors are rated at full voltage at 85°C, and withstand temperatures up to 250°C for short time loads of low voltage applications.

Circle No. 200 on Subscriber Service Card

PRECISION RESISTORS

Epoxy-encapsulated wire-wound precision resistors, vacuum impregnated and vacuum cast to eliminate hot spots have been developed by Kelvin Electric Co. The series EP resistors utilize tension-free winding techniques which reduce resistance drift with age, and shorts or opens due to thermal shock. The operating range is from —65° to 125°C and temperature coefficient is ±.000020°C.

Two types are produced in the series. 3/16" in diameter x 3/8" long and 1/4" diameter x ½" long. Other types are available to handle up to two watts dissipation.

Circle No. 203 on Subscriber Service Card.

ATOMIC FREQUENCY STANDARD

The development of the Atomichron by National Co. has produced a frequency-producing instrument providing frequency stability of 5 parts on 10^{10} and frequency accuracy of 1 part on 10^{9}.

The instrument uses the atomic principle of frequency control by comparing the precise resonance of the atoms of cesium with the output of a crystal oscillator to obtain stability said to surpass any frequency generator in existence. The unit is also self-monitoring and requires minimum adjustment and maintenance.

Circle No. .218 on Subscriber Service Card.

PLUG VALVES

Circle Seal Products Co. has announced new sizes available in their line of plug valves. The valves feature deadtight shut-off and external leakage prevention through the use of "O" rings. In the open position, the valve is full-ported and allows straight-flow passage. Valves are available in pipe sizes ¼", ½", and ¾" in brass. The ¼" size is also available in stainless steel with an aluminum handle.

Circle No. 216 on Subscriber Service Card.

PORTABLE FORCE CALIBRATOR

This portable unit is designed for calibrating existing weight, force and thrust measuring systems and has direct reading, automatic balance and digital servo indicator features. Produced by Gilmore Industries, Inc., the model 170 is said to provide 0.1% accuracy of reading or 0.1% of lowest range, whichever is greater. National Bureau of Standards calibration can be supplied by the manufacturer.

The model 170 uses a continuous balance servo system in a portable case and the indicator is calibrated with a precision strain gage load cell for tension or compression measurements. The instrument requires no batteries or standardization circuit. Provision is made for range suppression to increase the resolution and accuracy of the system. The complete unit is 6 9/16" wide x 13½" high x 16" deep.

Circle No. 211 on Subscriber Service Card.

PACKING GLAND

Conax Corp. is introducing its micro packing gland measuring 21/32" long and 11/32" hex. The new gland may be used to seal tubes of any material because the soft sealant makes it indifferent to tube composition. Increased fatigue strength and resistance to vibration are assured by reduction of stress concentration at the point of seal.

Temperature ranges of the gland with teflon sealant are —90°F to 500°F and seal pressures from 0.005 microns up to 1000 psi. Using lava sealant, temperatures range from —300°F to 1850°F with pressures from 0.005 microns up to 3000 psi. Standard bore sizes of the glands are 1/16" and 3/32" with 1/16" IPS thread and non-standard bore sizes ranging from .030" to .096" available on request.

Circle No. 214 on Subscriber Service Card.

ALL-ELECTRONIC CHOPPER

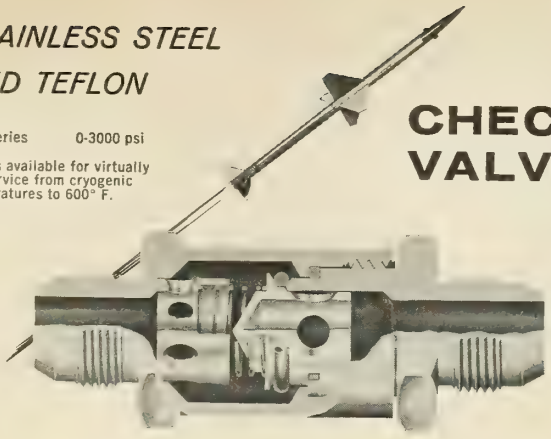
An all-electronic chopper containing no moving parts and having a minimum operating life of 5000 hours is available from the Kearfott Co. The unit converts usable DC into AC and vice versa.

Primary features include a zero phase shift, 180° dwell time, frequency range of 60 cps to 20 kc and an unlimited life when properly applied. Reference power is 6.3 V at 2 ma; load resistance is 1000 ohms to 1 megohm; load current 5 ma maximum; balance is —0°; and the ambient temperature range is —55°C to 125°C with no measurable output drift.

Circle No. 204 on Subscriber Service Card.

HIGH-TEMPERATURE ADHESIVE

The first successful adhesive system for stainless steel metal-to-metal bonds and honeycomb sandwich constructions capable of withstanding continuous exposure to temperatures up to 500°F have been developed by the Rubber and Asbestos Corp.



For stainless steel metal-to-metal bonds, the company produces Plymaster 1020, a tape of nominal 20-mil thickness. Testing the adhesive on type 302 stainless, 1" x 4" with a ½" overlap (steel thickness 0.050"), R & A Corp. established the following values: lap shear strengths of 1750 psi at room temperature; 1500 psi at 455°F after ten-minute soak; 1400 psi after conditioning 200 hours at 455°F and tested at that temperature; 800 psi after conditioning 400 hours at 455°F and

STAINLESS STEEL AND TEFLON

200 series 0-3000 psi

"Earliest History of Aeronautics"

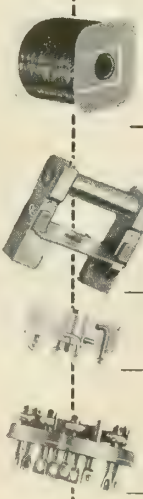
FLIGHT TEST 400 BC

Archytas and his wooden pigeon

Historians and archeologists have recorded legends and mythology dealing with flight as far back as 3500 B.C. However, it is not until 400 B.C. that history records the first actual flight experiment distinctly removed from pure mythology.

Archytas, brilliant Greek philosopher, scientist, mathematician and general, is credited with constructing a wooden, self-powered flying dove. While this historic episode has been discussed and investigated for twenty centuries, a logical scientific explanation is still lacking. Theories offered to explain the alleged flight have been many—a lighter-than-air wood unknown to us today, the use of a gas within the model, and even a mechanical device which may have been the forerunner of combustion engines. Most researchers think of Archytas' accomplishment as "possible but incredible."

Aeronautical Testing, 1957 A.D.



Today's aeronautical engineers and scientists make use of facilities such as Archytas never dreamed of... facilities like Aerotest Laboratories, a single source of complete aircraft and missile equipment testing—functional and environmental—in accordance with all military and commercial specs.

INTEGRATING RATE GYRO

A light-weight integrating rate gyro with self-contained temperature control has been designed by General Electric. The gyro's temperature control operates on the heat-of-fusion principle and is designed to maintain a temperature of 80°C with a tolerance of 1/3 degree or it can be altered to maintain other temperatures with the same low tolerance.

The complete unit, designated the KR-8, is 3" long, 2" in diameter and weighs only 1¼ lbs. It has shown a maximum wander of 6/10 degree for a period of more than four hours. The device's minimum life is 1000 hours.

Circle No. 202 on Subscriber Service Card.

SERVO-AMPLIFIER

A miniaturized, transistorized servo-amplifier for missiles application has been designed and is in production by Kearfott Co. The small, lightweight unit delivers a maximum power of 6 watts, is shock and vibration resistant and is a plug-in type component. Signal frequency is 400 CPS ± 20 CPS and the maximum signal input voltage is 30 volts. The unit's gain stability is rated at ±3db (—55°C to 71°C) and the entire device is completely potted.

Circle No. 215 on Subscriber Service Card.

MOTOR-TACH GENERATOR

A high temperature miniature motor-tach generator with low output to null ratio has been developed by John Oster Manufacturing Co. Type 10-MTG-6229-15 operates continuously in an ambient temperature range from —55°C to 125°C. Length is 2.131", null voltage .012, linearity 5% to 4,000 rpm, output voltage .3 per 1,000 rpm and excitation 18 v 400 cycles. Variations of voltage and shaft can be furnished to specification.

Circle No. 219 on Subscriber Service Card.

SILICON RECTIFIER STACKS

A new series of 170°C silicon rectifier stacks has been added to GE's line of semiconductor rectifiers. The units are rated up to 18 amperes per stack, and stacks may be paralleled for even higher currents. The standard stack is available with RMS input voltage ratings up to 3360 volts, and this may be increased by connecting in series. Operating temperatures range from —65°C to 170°C, with a maximum storage rating of 175°C.

people

Dean A. Harvey has been named director of contracts administration for the Associated Missile Products Corp.

Arthur H. Jones has joined Avco Mfg. Corp. as vice president, defense planning. He formerly was gen. mgr. of Motorola's military electronics center.

Norman L. Winter has been named manager of Sperry's Countermeasures group.

Dr. Charles H. Lutz has joined Hamilton Standard electronics department as chief of advanced design. **Dr. Lutz** was formerly with Arma Division of American Bosch Arma Corp.

Roy E. Wendahl, Hughes Aircraft Co. vice president and gen. mgr. of Tucson operations, has been named to the newly created post of vice president of sales. He will make his offices at the company's Culver City executive offices.

Wallace G. Wade has been appointed head of the Janco laboratory. He was previously with the standards laboratory of the Los Angeles department of Water and Power.

Dr. Raymond L. Garman has been elected to the post of chairman of the board of General Precision Laboratory, Inc. He will continue as technical director in charge of research and development. **James W. Murray** was elected president and chief executive officer, continuing as general manager.

Chester C. Utz has been named executive engineer of Chrysler Corp.'s defense operations division.

Lieut. Gen. Patrick W. Timberlake, (USAF, Ret'd) has been elected corporate vice president of Northrop Aircraft, Inc. He previously was commander of allied air forces in southern Europe.

Gladyn H. Putt has been named executive assistant to **L. Eugene Root,** vice president of Lockheed Aircraft Corp. and general manager of its missile systems division.

Philip D. Terry has joined Western Gear Corp. as regional marketing mgr. of aircraft & missile products for the eastern states.

G. J. Rauschenbach has been named director of sales for the Martin Co., moving from the company's Baltimore division to the Denver Division. He formerly was assigned sales management duties on all advanced design missile projects at the Baltimore facility.

HARVEY

JONES

Geoffrey Parsons, Jr., former director of information for NATO, has been elected vice president for Europe of Northrop International.

Dexter Rosen has been appointed administration department manager for Bell Aircraft Corp.'s guided missiles div.

James W. Walker has been named to handle Rocketdyne's export programs, formerly handled by North American Aviation's corporate export office.

Martin Boe, of North American Aviation, Inc., has been appointed to the post of air-to-surface missile engineering manager and **Sanford Falbaum** has been named ASM asst. engineering manager for the company. North American has also appointed **Dale D. Myers** project manager on the AF long range bombardment ASM development program.

Dr. Ernst A. Steinhoff will direct the Air Force missiles department at Aerophysics Development Corp. Since 1950, he has been technical director of Holloman air development center.

Dr. Thomas H. Johnson, Atomic Energy Commission research director, has been appointed manager of Raytheon Mfg. Co. research division. He resigned from the AEC, effective October 1.

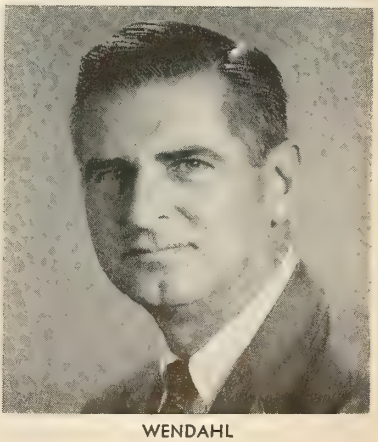
Cornell Aeronautical Laboratory, Inc. has been reorganized into six new divisions. Division heads are: **William F. Milliken,** full scale division; **Dr. Franklin K. Moore,** aerodynamic division; **Harold A. Cheilek,** engineering sciences division; **Robert H. Shatz,** systems research division; **Robert S. Kelso,** experimental facilities division; and **Dr. Seville Chapman,** physics division.

Brig. Gen. Robert E. Galer (USMC, Ret'd), former director of the guided missiles division of the Navy's Bureau of Aeronautics, has joined Temco Aircraft Corp. as mgr. of engineering programs.

John P. Broderick has joined the applications engineering department of Yardney Electric Corp.

Capt. Otis R. Hill has been appointed USAF Development Field Representative for a new San Francisco Bay area ARDC office.

Richard Driskell has been named engineering production manager of Humphrey Inc., directing control of the company's production of rate and free gyros, linear and angular accelerometers and other control instruments.



Four research managers have been named by the Government and Industrial division of Philco Corp. New managers and their phase of work are: **J. Forrest Bigelow,** radar and radio systems; **F. J. Bingely,** audio-video data systems; **C. P. Woodward,** missiles and advanced tactical systems, and **Ralph Deutsch,** fundamental

the new, completely revised
FALL-WINTER 1957-1958 EDITION

World Aviation Directory

Over 1,050 pages in one compact,
5" x 7½" ready reference volume.

Order copies now of this latest one-and-only World Aviation Directory of its kind. Lists over 31,272 key personnel (and job titles), companies, products, services, organizations. Complete information including addresses, phone numbers. All data are clearly classified and cross-indexed for fast reference through one handy source.

CONTENTS: Buyers Guide. Air Transportation Section. Manufacturing (aircraft, guided missiles, helicopters, power plant, propeller). Manufacturers and Distributors of Equipment. Special Aviation Services, including consultants. U. S. Terminal Airports. Aviation Publications, House Organs. Government Section. Foreign Section. Indexes of companies, personnel.

Edition limited. Order now. All orders must be sent in at one time to get discount price.

techniques. All previously with Philco.

Bernard B. Daien has been appointed chief engineer at Transistor Devices, Inc.

Josiah E. Smith, aerodynamicist, has joined the guided missile research division of Ramo-Woolridge Corp. in Los Angeles.

Dr. J. Howard Brown, Morton S. Kircher, and **Dr. Jack S. Newcomer** have been named as research managers in Hooker Electrochemical Co.'s realignment of its R & D staff.

Dr. James T. Grey, Jr. has been named scientific advisor to the Air Force's Directorate of Research and Development. Grey is head of the chemistry section of Cornell Aeronautical Laboratory, Inc., and will be on leave of absence while carrying out the new assignment.

Col. Arnold T. Johnson has been designated deputy commander of the ARDC's Arnold Engineering Development Center at Tullahoma, Tenn. Prior to assignment to AEDC, Johnson was chief of the USAF section, Military Assistance Advisory Group, Saigon, Viet-Nam. The AEDC is the wind tunnel test center for the Air Force.

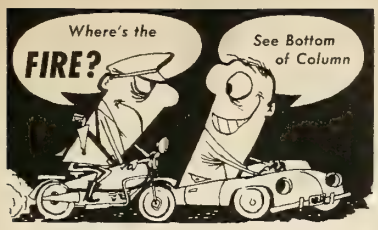
Robert G. Schmidt has been appointed project manager for the new $4-million plant of Callery Chemical Co. at Lawrence, Kansas. **Stanley J. Demski** is newly appointed construction manager for the plant, which will produce boron specialty chemicals.

Arthur J. Warner of Harlow, Essex, England, has been named director of research for Mycalex Corp. and associated companies. He will assume responsibility for materials and product development in the field of electronic components, glass-bonded mica, ceramoplastic insulation and synthetic mica.

Edward Rubin has been appointed assistant to the president of Wyle Laboratories, El Segundo, Calif., qualification and testing organization. He was previously manager of powerplant administration at Marquardt Aircraft Co.

Abraham Fuchs has been named head of the analytical department of CDC Control Services, Inc., producers of high-performance servo-mechanisms.

Richard W. Griffiths has been appointed director of sales for the components division of Litton Industries.



Dr. Arthur C. Ruge has been named director of research development of the electronics and instrumentation division, Baldwin-Lima-Hamilton Corp. Working under Ruge will be **Robert P. Lathrop,** newly-appointed manager of research and development for the division.

Harry McPherson has been chosen to head Temco Aircraft Corp.'s testing program for its missile weapons system. McPherson was previously technical design test coordinator for Convair in Fort Worth.

Sterling C. Spielman has been appointed director of engineering for Philco's Government and Industrial division, assuming full responsibility for all design and development activities. He will be assisted by **Frank D. Peltier,** named director for engineering planning.

Leonard Brewer has been assigned as project director for rocket engines in the solid propellant R & D department. Brewer was formerly with Thiokol Chemical Corp. in Huntsville, Ala.

Col. Carl W. Armbrust has been named executive officer in the Directorate of Procurement and Production, Air Materiel Command. Armbrust formerly served as chief of the airframe, missiles and engine section of AMC's Industrial Resources division.

Dr. Bernard Greifer has joined Atlantic Research Corp. as a member of the kinetics and combustion group. He was formerly with the U. S. Bureau of Mines. At Atlantic, he will conduct research in gaseous and solid combustion processes.

Col. Paul F. Nay, former director of aeronautics at ARDC headquarters, has been assigned to ARDC's field office in Los Angeles.

Lionel H. Orpin has been named director of plans and programs of Stromberg-Carlson division of General Dynamics Corp. He was formerly with the Convair division.

Dr. Oskar Mattiat has joined the Aerophysics Development Corp.'s engineering staff. He formerly was head of the special devices group at the Clevity Research Center in Cleveland, and also directed the electric wave filter section. Aerophysics also appointed **Dr. Robert B. Costello** as assistant manager of the materials department. He previously served as project engineer for Corning Glass Works.

J. F. Harrigan has been named manager of the Dayton liaison office jointly maintained by Reaction Motors, Inc. and Olin Mathieson Chemical Corp. He will be responsible for representing the two companies with the Air Force and area contractors. Before his appointment, he was with Lear, Inc. as contracts manager.

Dr. Lloyd H. Wilson has been appointed manager of the reentry body department of the Missile Systems Division of Lockheed Aircraft Corp. Also named as a manager was **Dr. Wayland C. Griffith,** of the flight sciences division in the research and development branch.

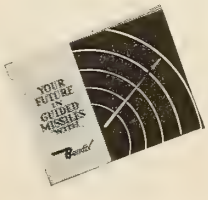
A POSTAGE STAMP CAN CHANGE YOUR WHOLE FUTURE

Sometimes little things can be mighty important. For example, a three-cent stamp can put in your hands a complete account of opportunities in the guided missile field.

The guided missiles business is the business of the future, and your future can be brighter with Bendix—the prime contractor for the important and successful Talos Missile.



Here at Bendix you will be associated with many of the world's foremost missile engineers. The work necessarily covers the broadest possible technical assignments with practically unlimited opportunity for advancement.

The thirty-six-page booklet, "Your Future in Guided Missiles", contains exactly the type of information every ambitious engineer should have.

It gives a detailed background of the function of the various engineering groups such as systems analysis, guidance, telemetering, steering intelligence, evaluation engineering, missile testing, environmental testing, test equipment design, reliability, ram-jet propulsion and hydraulics, and other important operations.

Mail this coupon today. It can bring you a brighter tomorrow.

Bendix—prime contractor for the TALOS MISSILE

Bendix Products Division—Missiles
412 I, Bendix Drive, South Bend, Indiana
Gentlemen: I would like more information concerning opportunities in guided missiles. Please send me the booklet "Your Future In Guided Missiles".

For additional information about any product or service advertised or mentioned in the editorial pages of this issue of Missiles and Rockets:

Use the attached prepaid reply cards. Circle numbers shown on the reply card that correspond with numbers appearing beneath items described. If no circle number accompanies the article or advertisement, give page number (and advertiser's name) on line provided at bottom of the card.

Your requests for information will be forwarded promptly to the companies concerned.

NEW PRODUCT BRIEFS

OXY ADHESIVES. When cooled to 0°F, epoxy synthetic glue holds some ht metals together with enough ength to withstand a force of 8000 . psi. The synthetic adhesive does not come brittle with sudden and ex- me changes in temperature and in- eases in strength as the temperature ops. National Bureau of Standards.
cle No. 251 on Subscriber Service Card.

OXY-SATURATED INSULATION. Two w types of epoxy-saturated electrical ulation for class B applications are ailable. The asbestos-base products said to have unique electrical and rmal properties. The material is avail- le in rolls, tape or sheet form. Johns- anville Corp.
cle No. 252 on Subscriber Service Card.

XIDE SCALE REMOVER. A process removing oxide scale from titanium s been developed by Temco Aircraft rp. The electrolytic process removes scale without the use of acids or nd labor.
cle No. 253 on Subscriber Service Card.

LICONE RESIN. This material for nding low-pressure structural laminates parts to glass cloth the qualities us- ly associated with polyesters. It was veloped for the vacuum-molding of mplex structural parts, provides high ength at elevated temperatures, has dielectric losses and is available in mmercial quantities. Dow Corning rp.
cle No. 254 on Subscriber Service Card.

ANSISTORIZED CONVERTER. A nsistorized 30 amp constant conver- featuring current stabilization, selec- n of current levels in 50 ma steps m ½ to 30 amps, and numerous test- applications and other features have en developed by North Hills Electric . Inc.
le No. 255 on Subscriber Service Card.

ULTI-FUNCTIONAL INSTRUMENT. med "Voca," this instrument com- es a precision differential null type entiometric voltmeter and calibrator AC, DC and VTVM. Used for pro- tion line testing, calibration of mul- eters, vacuum tube voltmeters and illoscopes, circuit test and design other applications. Demolab Corp.
e No. 256 on Subscriber Service Card.

CISION TRIANGLES. Layout trian- of consistent precision, designed to lace metal triangles in many appli- ons, have been produced by the gorukov Mfg. Co.
e No. 260 on Subscriber Service Card.

TUBE CLAMPS. A line of "Kool Klamps" designed to provide adequate cooling and easy tube changing as well as to retain miniature tubes under extreme vibration and shock is available. The new clamp features an ejector pin to facilitate removing tubes in restricted chassis areas.
Circle No. 257 on Subscriber Service Card.

COAXIAL TERMINATORS. Stoddart Aircraft Radio Co. is producing a coaxial terminator of 9/16" diameter with precise resistance values from DC to 1000 mc. VSWR on the unit is less than 1.20 to 1000 mc, characteristic impedance is 50 ohms and the peak voltage is 100 volts. The component is available with either type BNC or TNC male or female connectors.
Circle No. 258 on Subscriber Service Card.

CONSUMABLE WELD INSERTS. Use of EB weld inserts permits welding from one side of metal and eliminates need for back-up rings in welding of tanks for missiles. Tensile strength of 200,000 psi is developed in the weld metal by heat treatment. Arcos Corp.
Circle No. 259 on Subscriber Service Card.

COAXIAL PUSH-BUTTON DISCONNECT. RF coaxial connectors with a built-in push button disconnect switch eliminate the necessity of removing the cable from an assembly. Available with type "N" and "HN" hermetically sealed receptacles. Don-Lan Electronics Co.
Circle No. 261 on Subscriber Service Card.

RESOLVER. High-accuracy and impedance size 15 resolver features tuned impedance of 10,000 ohms and accuracy of ±0.1% from —55°C to 85°C with amplifier. Norden-Ketay Corp.
Circle No. 262 on Subscriber Service Card.

PROXIMITY SWITCH. Manufactured to detect ferro-magnetic objects without coming in contact with the object. The unit has no moving parts and may be mounted on a surface extending only 3¼" from the material which operates it. Excitation is 100-125 V, 60 cps, 2 watts (nominal). Minneapolis-Honeywell.
Circle No. 263 on Subscriber Service Card.

RATIOMETER. Servonics, Inc., has introduced a new Unity Ratiometer featuring fast accurate readout, continuous balance, automatic polarity indicator and complete self-containment.

The device has unlimited application with DC analog computers and is equipped with an output shaft extension.
Circle No. 264 on Subscriber Service Card.

MISSILE LITERATURE

TRANSISTOR MANUAL. The second edition of a transistor manual containing basic information on transistors and their use in electronic circuits has been published by GE. Included in the 112-page manual are data on semiconductor theory, construction techniques, explanation of symbols, specifications (with drawings) of all transistors currently registered with the Electronic Industries Association, and other pertinent data. General Electric Co.

Circle No. 150 on Subscriber Service Card.

AERODYNAMICS RESEARCH. Three reports of aerodynamics research for USAF, two of them on wind tunnel tests and the third on ignition and combustion, have been released to industry. OTS, Dept. of Commerce.

Circle No. 151 on Subscriber Service Card.

TRANSITOR SERVO AMPLIFIER. Four-page brochure giving performance characteristics of miniaturized units. Covers models of the 60 and 400 cps TRAMPS. M. Ten Bosch, Inc.

Circle No. 152 on Subscriber Service Card.

TIME-RATE INDICATOR. Applications of a 10 mc time-rate indicator for measuring frequency, counting pulses per unit time, measuring interval between pulses, and other similar operations are discussed in bulletin 501A-B, published by Laboratory for Electronics, Inc.

Circle No. 153 on Subscriber Service Card.

COMPANY INFORMATION. Information on the various aviation divisions of Kelsey-Hayes Co. is listed in a 32-page booklet just released. Products and services available are listed in the free booklet. Kelsey-Hayes Co.

Circle No. 154 on Subscriber Service Card.

PIEZOELECTRIC CRYSTALS. A revised edition of the Air Force's "Handbook of Piezoelectric Crystals for Radio Equipment Designers" has been released. Prepared as a guide for designers of military electronic devices, the manual contains a comprehensive examination of piezoelectric control of radio frequencies. It includes background material, circuit theory, components data and other information. The 702-page manual is sold for $7.00 through OTS, Dept. of Commerce.

Circle No. 155 on Subscriber Service Card.

OPTICAL TOOLING. The basic principles of optical tooling are described in a 56-page manual which includes photographs and drawings. Major instruments and accessories used in optical tooling are covered, and drawings show the optical principles used in applying the equipment. The application of optical principles permits tolerances as close as thousandths of an inch to be held at distances from a few inches to as much as a mile. Keuffel & Esser Co.

Circle No. 156 on Subscriber Service Card.

HYDRAULIC SYSTEM TESTER. A universal hydraulic accessories test machine is the subject of this brochure, which describes the machine's operations on valves, actuators, regulators, plumbing, tube and hose lines, manifolds, and other accessories. The machine simulates actual flight conditions and is said to test hydraulic components to the most rigid specifications. Greer Hydraulics, Inc.

Circle No. 157 on Subscriber Service Card.

CLOSED CIRCUIT TELEVISION. Indus trial closed circuit television systems and accessories are described in a catalog recently published. It contains data on remotely controlled pan-tilt, iris-focus and other camera accessories, specia "ruggedized" equipment for operation under adverse environmental condition of noise, heat, shock, and temperatur and humidity extremes. KIN TEL Divi sion, Cohu Electronics, Inc.

Circle No. 159 on Subscriber Service Card

MAGNETIC AMPLIFIERS. Two report of research for the Armed Forces o standard and two-core magnetic ampli fiers are available through OTS, De partment of Commerce.

Circle No. 160 on Subscriber Service Card

METALLURGY STUDIES. The impac properties of boron-treated steels ca be disrupted by titanium introduced i boron addition agents, according to on of two new reports now available to in dustry. The other deals with a revie of work on development of a substitut material for a cobalt-based alloy. OTS Department of Commerce.

Circle No. 161 on Subscriber Service Card

TRANSISTOR ANALYZER. Four-pag bulletin describes model BCT-300 tran sistor curve tracer and includes bloc diagram showing the variety and func tions of the unit, as well as specifica tions. Norden-Ketay.

Circle No. 162 on Subscriber Service Card

NEUTRON SHIELDING. A folder o boral for neutron shielding, showing th material's composition, uses and shield ing properties, is available fro Brooks & Perkins, Inc.

Circle No. 163 on Subscriber Service Card

ROCKET DESIGN. Discussion of theo and practical application of rocket e gine design are among subjects covere in a new issue of "Thiokol Facts," house organ. Other articles include se lant applications and test equipmen Thiokol Chemical Corp.

Circle No. 164 on Subscriber Service Card

METAL FASTENERS. An eight-pag guide for design and assembly socket-head cap screws has been pu lished, giving physical characteristic thread lengths, torque tension data a other information useful in efficient a plication of the fasteners. Strong, Ca lisle and Hammond.

Circle No. 165 on Subscriber Service Card

PLASTIC TUBULAR CAPACITOR. E gineering bulletin describing type B plastic tubular capacitor for printed c cuits has been published and is ava able from Pyramid Electric Co.

Circle No. 166 on Subscriber Service Card

RUBBER PRODUCTS. Illustrated catal showing facilities for manufacturing ru ber parts to customer order. Empha is placed on special molded rubb parts, silicone rubber parts, rubb bonded-to-metal parts and other de on rubber synthetics. Williams-Bowm Rubber Co.

Circle No. 167 on Subscriber Service Card

CERAMIC RESEARCH. A 20-page b chure picturing and describing their f cilities for exploratory and developm tal work in industrial ceramic techn ogy has been published by Gladdi McBean & Co.

Circle No. 158 on Subscriber Service Card

HOT COMPONENTS

for the powerplant industry

The Aircraft Division of Rheem is currently delivering production quantities of high temperature non-rotating components for many of the most recent jet engines. Rheem's production capabilities are now being applied to the requirements of the powerplant industry... on the specialized problems associated with the fabrication and assembly of heat resistant materials.

Rheem's experience and facilities are available for application to new challenges in air breathing and rocket powerplant production.

Our Marketing Department will answer your inquiry promptly.

View of Rheem Downey facility showing the area now devoted to jet engine production

RHEEM MANUFACTURING CO./AIRCRAFT DIVISION

11711 woodruff avenue, downey, california

The research and development activity at Rheem is engaged in the conception, evaluation and design of • Drone and Small Missile Systems • Explosive and Ordnance Products • Propulsion System Analysis

Engineers: join the 600 Rheem engineers in challenging technical work. Send resume to Personnel Manager, Aircraft Div., Rheem Mfg. Co. All inquiries held strictly confidential.

rocket power from reasoning power

A *reasoning* mind—man has always found this his most useful weapon when venturing into unknown fields. Today's frontier—one of the greatest unknowns ever faced by man—lies in outer space.

RMI, America's *first* rocket family, is uniquely qualified to help our country conquer the new frontier. For this project will require more powerful and more efficient rocket propulsion systems than any yet designed. And RMI's experience in the rocket power field extends back over 15 years . . . years in which RMI scientists and engineers pooled their reasoning power and knowledge to develop entirely new methods of propulsion and to produce rocket powerplants for dozens of military vehicles.

With this backlog of experience—and with an increasing staff of imaginative, reasoning engineers—RMI continues to blaze trails in many fields of rocket power: supersonic manned aircraft . . . versatile helicopters . . . catapults and test sleds . . . and missiles for defense and space exploration.

Engineers, Scientists—Perhaps you, too, can work with America's *first* rocket family. You'll find the problems challenging, the rewards great.

Target Team

The U.S. Army's ground-to-air missiles require realistic training targets with speed, altitude capability and radar reflectivity that closely approximate the same characteristics of an invading enemy aircraft. In matching these specifications, however, cost becomes a major consideration.

By air launching a rocket target from a drone at high altitude, the cost of development and operation decreases and the training program gains efficiency. From these critical requirements grew Radioplane's concept for the RP-77DL and RP-76A target team.

Radioplane's turboprop drone, the RP-77DL, is ground launched carrying the rocket-powered RP-76A target. Upon reaching scheduled altitude the RP-76A blasts off to complete its target mission. The RP-77DL then returns to launch site under radio control to be readied for another team launching. Both the launch drone and the rocket target are recoverable by parachute.

First in the field of producing remotely controlled aerial targets, Radioplane continues this vital production while developing economical aerial target systems for tomorrow's missile training programs.

ASCOP C SERIES MONITOR SCOPE

QUICK CHECK-UP

For Flight Instrumentation . . . For Production Line Testing . . . For Industrial Process Monitoring

Inspect up to 86 Test Points . . . at a glance!

With the ASCOP "C" Series Monitor, missiles and airframes can now be tested on the production line or in flight. Costly instrumentation programs can be insured against incomplete results . . . guesswork is eliminated.

Industrial manufacturers can employ it to great advantage if their product involves multiple inspection on the assembly line. A quick look at the Monitor Scope tells if the product passes inspection. Up to 86 variables can be checked at a glance.

Where personal inspection is costly, difficult or dangerous the ASCOP Monitor Scope is invaluable. Employ it for continuous data inspection of mixtures, pressures, flows, temperatures and other vital information required in the nuclear, chemical, petroleum or related fields.

An option of 8 sampling speeds is available with a choice of any 5. Two types of displays are provided . . . "A" scan display for checking individual data pulses, and a vertical lines display showing a composite picture of all data channels. Provides excellent visual accuracy.

The ASCOP Monitor Scope is a rugged unit for field or laboratory use designed to operate well under extremes of vibration, acceleration, noise and other difficult environmental conditions.

Our competent staff of sales engineers is available to aid you in your application of this equipment.

PRODUCTION LINE

Speeds up tests and reduces errors on the production line. Checks 14 units in rapid sequence by the flick of a switch. Provides a "quick look" at up to 86 variables at one time for each unit. Limits can be marked on the tube face with a grease pencil or crayon.

RAMP CHECK-OUT

The ASCOP Monitor Scope is portable . . . can be mounted on a mobile dolly or in a van and moved to a launching site to give a missile, rocket or aircraft a complete pre-flight check.

IN-FLIGHT

Used in aircraft to provide the flight test engineer with vital data while a test flight is underway. Assures that data is being properly recorded in a magnetic tape data recording system. When used on the ground in conjunction with a radio telemetering system, provides complete in-flight missile monitoring.

"QUICK LOOK" EDITING

The ASCOP Monitor Scope is especially suited for "quick look" editing of large volumes of data during a test, or from magnetic tape playback prior to processing.

MINIATURE TWO PEN 5" RECORDING POTENTIOMETER

Transistor Amplifiers

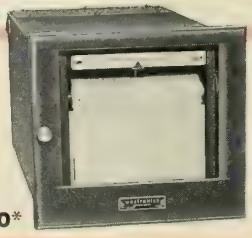
exclusive from...

westronics®
INCORPORATED

$1195.00*

THE ULTIMATE IN AN ACCURATE, READABLE, MINIATURE RECORDING POTENTIOMETER, WITH THESE ADVANCED FEATURES

- 5-inch strip chart record.
- Two pens, each traveling the full 5 inches.
- 1-second maximum balancing time.
- Table top or panel mounting.
- Panel space 9⅝" W x 8½" H
- Margin marker pens.
- Paper supply indicator front of recorder.
- Ball bearings in pen drive system.
- New concept in front set limit switches.
- 0.5% accuracy on both pens.
- Completely transistorized amplifiers, no vacuum tubes.
- MV or TC Calibration
- Minimum Span: 1 MV
- Standardization: Mercury cell.
- Simple sub-assembly type construction for easy maintenance. (Entire recorder rolls forward out of case.)



PLUS THESE OPTIONAL FEATURES:

- One front set SPDT switch and 3 SPDT back set switches each independently adjustable over the entire range on each pen.
- Transmitting slidewires.
- Selsyn motor chart drive.
- 3 speed quick change chart drive.
- Left and/or right margin marking pens.

WESTRONICS RECORDING POTENTIOMETERS FOR EVERY NEED

One Pen Miniature 5" Recording Potentiometer

- 5" strip chart record.
- Continuous Automatic Standardization with electron tube amplifiers.
- Requires only 9⅝" by 8½" panel space.
- Accuracy better than 0.5%.
- One second full scale pen travel.
- Weighs less than 25 pounds.

$490.00*

Two Pen 11" Recording Potentiometer

- 11" strip chart recorder (12" overall width).
- Completely transistorized amplifiers.
- Reduced maintenance.
- Small size.
- Immediate recording . . . no warm-up time.
- Optional synchronous motor or Selsyn motor chart drive.

$1495.00*

Complex Geometry of Impellers and Nozzles Cast in One Piece by Kolcast

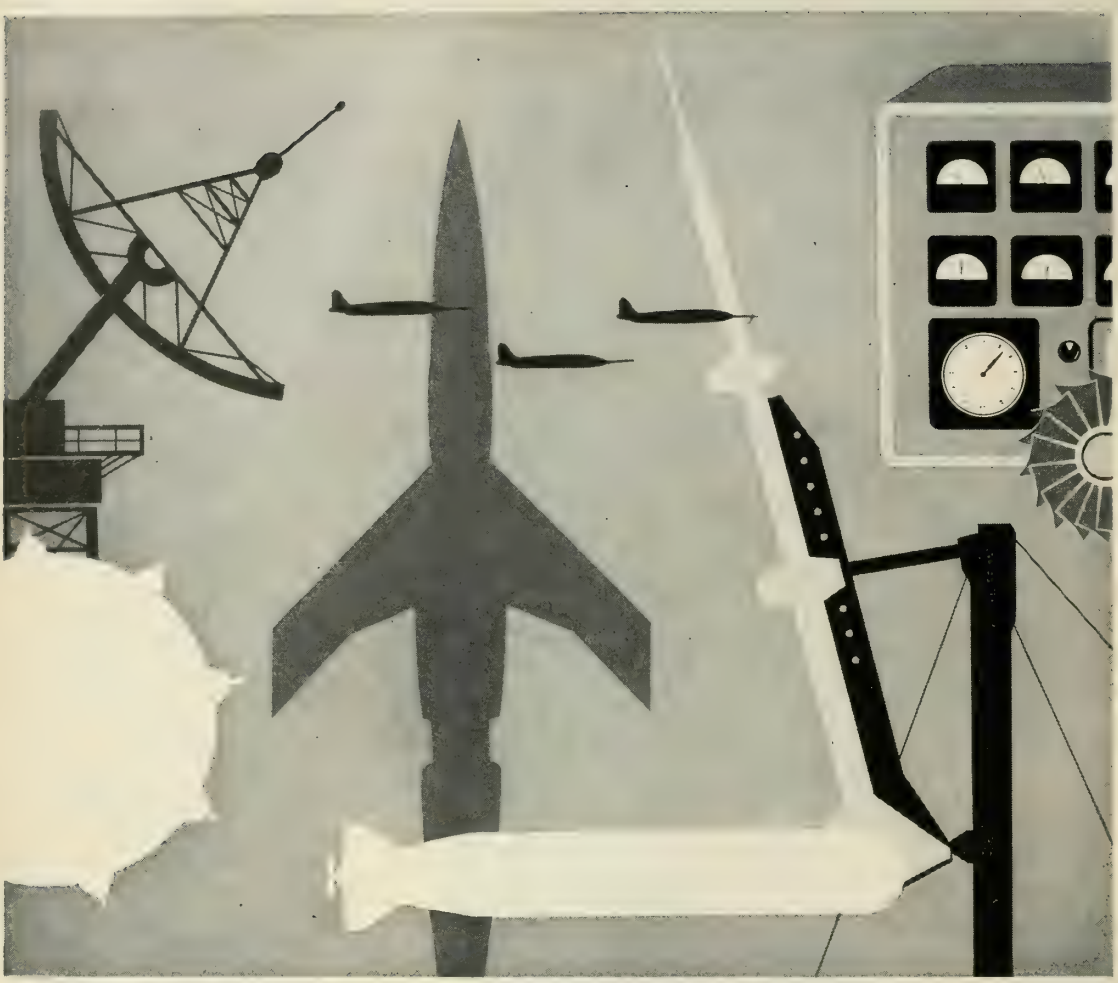
Gas turbine engine nozzle cast in Hastelloy C by the Kolcast process.

Design any complex curve you require into your missile-engine turbine parts . . . we can cast it in the alloy of your choice exactly as you draw it on paper.

The Kolcast process of casting with permeable inorganic ceramic molds removes all limitations from the production of even the most complex mathematical designs. Castings are one-piece for uniform metallurgy. They are free from welded seams, fastened segments, or stress concentrations.

Parts produced by Kolcast can be as small as a cigar, as large as a washing machine . . . can weigh ounces, or as much as 500 pounds. Material selection includes super-alloys, as well as all the popular, high-temperature steels.

Kolcast parts can be cast with finishes and contours so accurate that they require little or no machining for final assembly. You save time and high-rate labor, eliminate costly scrap and high-burden machine tools.



A Kolcast sales engineer will call at your convenience to help you and your engineers design parts that require no production compromises. Meanwhile, write for Booklet MR-11.

Throughout the Pattern of Modern Defense...

AMF has experience you can use

• Most defense problems fit into AMF's "big picture"... a picture drawn from AMF's tremendous backlog of experience in defense work. Wherever you are, there's probably an AMF defense component or integrated system... a product of AMF experience... operating near you. • Guided missiles ride on AMF equipment to AMF launching sites ... to be loaded, fueled and fired by AMF-built equipment. Under the sea, AMF-built weapons wait for unfriendly submarines on the prowl. Along our borders, AMF radarscopes search the sky for "stranger" aircraft. • There is little room for failure where the job is the nation's defense. And the nation looks to companies like AMF to design, test and produce a variety of defense products. With a wide range of experience in the most sensitive fields of defense work, AMF may well be the answer to your problems... in defense or industry.

If it can be put on paper...

Above you see a solid propellant rocket core mold being completed after taper milling and contour turning by a Diversey craftsman. Diversey produces so many tough and intricate missile components similar to the above that no wonder everyone calls them the most versatile missile metal machinists in the USA. Diversey does outstanding work in the machining of missile components because they have the largest facilities, the finest machinists and top flight engineering.

If it can be put on paper, Diversey can put it into metal.

HYDROSPINNING NOW AVAILABLE

A new Hydrospinning Division has been formed at Diversey which uses the latest and largest equipment to produce intricate missile parts.

An Open Letter to President Dwight D. Eisenhower

Mr. President:

This is the age of science. This is the era of intellectual, uninhibited thinking. Tomorrow is here. And you, as the leader of the greatest nation on earth, must see to it that this nation will be out in front as mankind advances into the space age.

Until recently many of your top-level officials have considered space flight trivial and irrelevant. Space travel was something for science fiction writers and comic strip authors. Even within the Air Force, officials and officers were not to mention or discuss space flight. Our government's top policy makers refused to heed the scientists and engineers who predicted many years ago that tomorrow's war would be fought with space weapons, and that the nation which controlled space would control world peace and the destiny of mankind. These top officials, we hope, soon will begin to see the light. Mr. President, you must lead the way.

Overnight the American people have learned that in spite of their material wealth, in spite of wrap-around windshield automobiles and chrome-plated washing machines, in spite of superhighways and supermarkets and our high standard of living—the world is questioning our leadership of world power.

We have been shown that the current World War III is a battle of the minds. The nation that demonstrates its technical superiority effectively and dramatically to the rest of the world will profoundly influence the minds of men. The American public is beginning to understand this. The extent that our government policy makers understand it can determine our destiny.

In the eyes of some billion-and-a-half people, Russia now is becoming such a leader, and it will take an immense effort to overtake her. The mere stepping-up of our missile program and sorting-out of our inter-service missile rivalry problems won't do the trick. Pooling our scientific know-how with our allies won't do it either. The problem is more basic.

It begins with the materialistic attitude toward modern day living and our indifferent attitude toward science. Lack of scientists? Of course! Scientists are individualists, and individualism is on the wane in this country. Must we remain at the point where it takes an Admiral Rickover to get things done?

Many of this country's outstanding scientists were born in Europe. Many of them came here to become citizens of this great country because they thought they could accomplish more in an atmosphere where one supposedly has intellectual freedom and a greater understanding of mankind's progress and of things to come. How disappointed these scientists must be today!

More than ever, Mr. President, we now need leadership. We are looking to you for this. We need uninhibited thinking at Cabinet level. We need a scientist at Cabinet level, a Secretary of Science. We also need a space flight program. We must consolidate and pool our scientific talent, possibly through a National Advisory Committee for Astronautics or an Astronautics Commission, with a definite schedule and timetable for the conquest of space. We must take the initiative to become first in satellite science. We must put man into space; we must put man on the moon and on our two nearest planets. The United States must show the way. If she does not, Russia will.

We must do all this within 20 years or less and we must start the planning for such a program immediately, for two reasons: 1) Such a program will yield tremendous scientific victories which will benefit our entire human race in numerous ways. 2) Such a program will restore supremacy to the free world and in particular to the United States. This, Mr. President, will mean for us a total

victory of democracy over slavery. Scientists and military planners must advance hand-in-hand to achieve this.

In order to accomplish this we must start at the basic research level. Instead of cutting funds for research and development, we must increase them. Research is the key to scientific and military achievement.

You now have the opportunity to reorganize our missile defense system and to start a space flight program. For the time being it is not so much a matter of granting more money for defense as a matter of organizing the expenditures and our scientific talent.

Obviously, we must spend more money in the future on a space flight program. John Q. Public understands the grave and alarming mess we are in, whether your Cabinet members do or not. He doesn't like to, but he will pay higher taxes if he can be assured that this nation will regain its Number One position in the world.

Actually, we have a lot of money in the bank for a space flight program. And we have the talent. *Jupiter* and *Thor* are duplicate programs initiated to perform duplicate functions. Seemingly one must go, but both have cost many millions of dollars; both have drawn heavily on available technical manpower.

The superficial solution is to decide that the full cost of one program and one missile team must inevitably be wasted—be lost to the country—a "necessary price" paid in the crash development of modern weapons.

This, Mr. President, is not so. There is a sound solution. If *Thor* proves to be the best weapon of the two IRBMs, do not cancel out the *Jupiter* team and money as a total loss, but shift the team and its hardware to America's inevitable space flight program. Special configurations of the *Jupiter*—or the *Thor*—are capable of putting up satellites of 1000 pounds weight. We could achieve this within months. Either missile represents a valuable piece of hardware for practically any preliminary space flight project. With this approach we can catch up with the Russians two to three years sooner —without slowing our military program—than if we repeat the approach we used in developing the *Vanguard* "me too" satellite.

The same technique can be used with our *Atlas* and *Titan* ICBMs. The missile not selected as a weapon must enter our future arsenal of space flight vehicles. So must the scientific team behind that missile.

Employing this approach, we will save the taxpayers millions, possibly billions, of dollars. The decision to pursue this goal and employ this technique must be made now.

Of course, we will have all kinds of investigations as soon as Congress convenes. And this is right. Senators and Congressmen need no urging to do something about our present confused situation; spontaneously they vow "something will be done about it" as soon as Congress convenes.

In all probability, Congress will throw some light on the confused background of our missile and satellite program. Incidentally, we hope Congress will also make public the names of the members of the nine-man committee that turned down the offer to use military hardware to launch the first U.S. satellite. It may be a waste of time to discuss at this time what we could have done and did not do. Nevertheless, for the record this is important. If nothing else, it will help sort out the incompetent from the capable, and it might give us a pointer as to where we will find the best-qualified scientists and leaders to conduct the kind of future space flight program this country so desperately needs.

We are not so sure that the U.S. is employing the best-qualified people at this stage of the game. Many missile industry people have questioned us about the capabilities of some of our current "space flight experts" (people who seem to have become space-minded overnight) and why we have not employed our true space flight scientists in the current IGY satellite program. We have no ready answer for them.

Yes, in the eyes of the world, the American satellite program now has become a "me too" project.

We urge you, Mr. President, to look at space flight as any other American institution, because sound, business-like competition would have put us out in front. The approach that has provided us with more washing machines and paved highways than the rest of the world also could have kept us the strongest nation in the world. No other approach will help us regain the ground that we have lost to Russia. No other approach will help us win the battle for the minds of men.

Those of us who talked with members of the Russian delegation at the space flight meeting in Barcelona recently heard these scientists all openly confirm the fact that Russia has a full-fledged space flight program. And you know, Mr. President, we don't have one!

The Russians have a definite timetable for their bigger satellites, for their different kinds of moon rockets and flights to the planets and manned, military space vehicles. In view of their technological advances in recent years—which they have proven beyond doubt—we can no longer afford to doubt any of their scientific claims.

Cost is of no importance to Russia. The Russian people might be starving; there may be a shortage of bread, soap, gasoline, clothing in the Soviet Union; but the world doesn't worry about this when the Russians send satellites and moon rockets aloft. Because this proves to the world that the Russians possess the ability to smash the Western World by missile bombardment.

Let us not fool ourselves, Mr. President; it takes more than power to put up a satellite. For years our missile engineers have tried to solve the structural problems created by high accelerations, tossing and stress in a missile, and for years they have tried to solve the guidance problems. Without solving these problems, you cannot launch a satellite. The Russians have solved them. We are still working feverishly to do so.

We must strip away this complacent feeling that we have held—that what the Russians can do, we can do better. This is probably true (for we undoubtedly have the better scientists). But in this race—and it is a race—the prize goes to the first achiever. The prize, of course, is world leadership.

The obvious lag in missile and satellite development could be fatal. It is not enough to say that for the present we have military superiority, which is doubtful anyway. We must demonstrate to the world our ability to exceed Russia in the scientific field and thus insure that free men will never become victims of communism through fear or default.

These potential new weapons are not toys. The nation that first controls space will control the world. The choice is democracy or slavery.

Let's get away from the attitude that the Russians "probably" haven't solved this problem or that problem. The launchings of their first *Sputniks* and space rockets are much, much more than "neat scientific tricks." You know it. The American people know it. And the American people expect you to do something about it.

You don't have to be a scientist, Mr. President, to solve this problem. You must be a leader.

Second World Metallurgical Congress and 39th National Metal Exposition, International Amphitheater, Chicago, Ill., Nov. 2-8.

Institute on Electronics Management Meeting, Automatic Data Processing System, American University, Washington, D. C., Nov. 4-8.

Joint Military-Industry Guided Missile Reliability Symposium (security clearance required), Naval Air Missile Test Center, Pt. Mugu, Calif., Nov. 5-7.

IAS Weapons System Management Meeting, Statler-Hilton Hotel, Dallas, Texas, Nov. 7-8.

IRE, Instrumentation Conference and Exhibit, Atlanta, Georgia, Nov. 11-13.

Vickers Aircraft Hydraulics Conference, Park Shelton Hotel, Detroit, Mich., Nov. 12-13.

National Aviation Trades Assn., 18th Annual Convention Hotel Adolphus, Dallas, Nov. 13-15.

National Plastics 8th Exposition, International Amphitheatre, Chicago, Ill., Nov. 17-21.

International Air Transport Assn., Technical Conference, Miami, Fla., Nov. 18-29.

Aviation Distributors and Manufacturers Assn., 30th Meeting, Sheraton Cadillac Hotel, Detroit, Mich., Nov. 20-22.

DECEMBER

ASME Annual Meeting, Hotel Statler, New York, Dec. 1-6.

American Rocket Society Annual Meeting, Hotel Statler, New York, N. Y., Dec. 2-6.

High Temperature Strain Gauges, Symposium, Aeronautical Structure Laboratory, Naval Air Materiel Center, Philadelphia, Pa., Dec. 4-5.

ARS 1957 Eastern Regional Student Conference sponsored by the Polytechnic of Brooklyn Chapter, Hotel Statler, New York, N. Y., Dec. 6-7.

Gas Turbine Development Meeting, Speaker; Rear Adm. S. B. Spangler, USN, Air Development & Materiel Center, at Engineers Club, Philadelphia, Pa., Dec. 18.

JANUARY

IAS 26th Annual Meeting, Sheraton-Astor Hotel, New York City, N. Y., Jan. 27-31.

American Astronautical Society, Fourth Annual Meeting, New York City, N. Y., Jan. 29-31.

Seventh Annual Instrument Short Course, sponsored by Southern California Meter Association and Los Angeles Harbor Junior College, Wilmington, Calif., Jan. 30-31.

MARCH

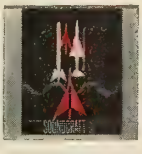
Nuclear Congress, International Amphitheatre, Chicago, Ill., Mar. 16-22.

Aviation Division Conference, American Society of Mechanical Engineers, Statler-Hilton Hotel, Dallas, Tex., Mar. 17-21.

Atomic Industry Trade Show (in conjunction with the 1958 Nuclear Congress) International Amphitheatre, Chicago, Ill., Mar. 17-21.

One tape can't serve all recording needs in magnetic instrumentation

There are differences between pulse and carrier recording . . . therefore the tapes used in these systems must have different characteristics. Only in Soundcraft Instrumentation Tapes are these distinct and separate properties engineered into the oxide formulation. Soundcraft then adds two original processes — Uni-Level Coating and Micropolishing — to achieve the surface perfection found exclusively in the most advanced tapes of our time:



Soundcraft Type A Tape for Digital Recording

Soundcraft Type B Tape for Telemetering

Get the Soundcraft Tape that's made for your application . . . get error-free recording!

RCCH oxide formulation gives "Type A" higher signal output and greater retentivity plus unique surface hardness for controlled tape wear rather than uncontrolled equipment wear.

The special FM formulation in "Type B" is a highly refined form of gamma Fe_2O_3 oxide with high temperature binders, lubricants and anti-static agents to assure uniform speed and tape-to-head-contact — preventing flutter.

HONEYWELL DEVELOPS TOMORROW'S RADAR FUZING

Honeywell, major producer of radar fuzes since 1951, is deeply involved in the research and development of new fuzes for the weapons of the future.

In creating these new and advanced radar fuzes, Honeywell Ordnance engineers have placed maximum emphasis on performance, simplicity and lowest possible production costs. Seeking ever-more reliable performance, they have developed unique new circuitry for immunity to countermeasures.

Developing successful electronic controls since the late 1930's—Honeywell engineers have made the first application of electronics to autopilots, potentiometers and temperature controls. This has led to Honeywell's successful development and production of a wide range of military electronic control systems—including computers, stabilized platforms, fire control systems and sonar systems.

New and expanded facilities, outstanding engineering talents and proven performance in the exacting field of radar fuzing make Honeywell Ordnance well suited for all phases of fuze development—from feasibility studies to high volume production.

For further details, phone, wire or write to Honeywell Ordnance Division, Dept. MI-11-261, Hopkins, Minnesota.

Honeywell Diversified Systems Span the Field

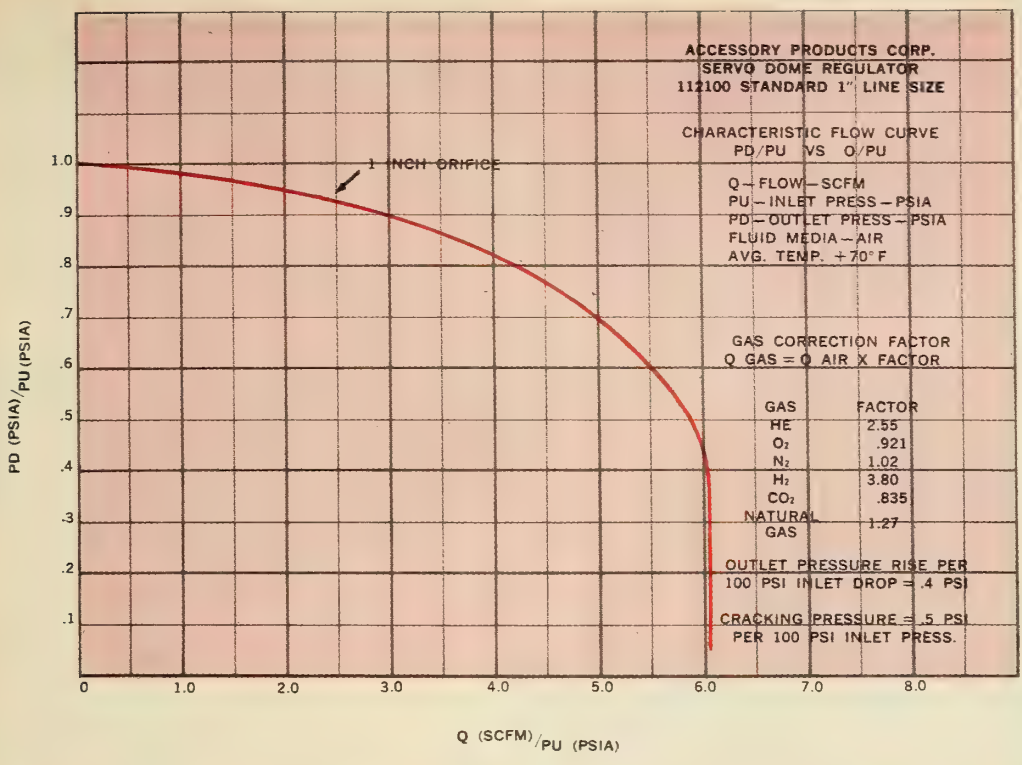
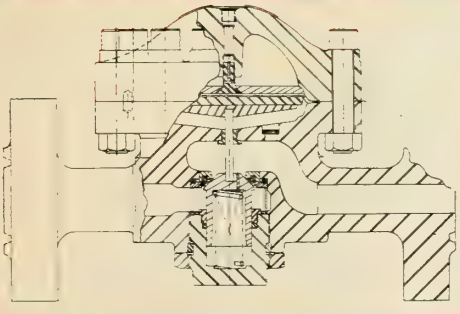
new design achievement by APCO

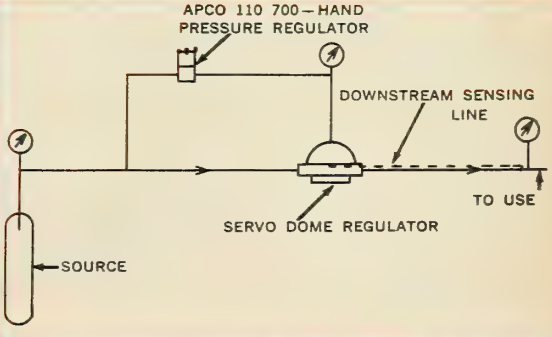
...THE SERVO-DOME PRESSURE REGULATOR



in stainless steel, aluminum, alloy steel, or bronze



Reduction of initial air, gas or liquid pressures to optimum delivered pressure, and/or flow and continuous control thereafter...with extreme accuracy and operational versatility ... is now possible with APCO's new Servo-Dome Pressure Regulator.



Check these outstanding performance features:

- ***Line sizes and orifice sizes from ¼" to 3", e.g. 3" line—3" orifice!***
- ***Inlet pressures from 0 to 6000 psi!***
- Outlet pressures from 0 to 5500 psi!
- Positive shut-off—zero leakage!
- Balanced poppet feature provides:
  - Longevity of seat life from low seat load!
  - Low diaphragm ΔP at any given pressure conditions!
  - Cracking pressures minimized!
  - Dampened downstream surge due to inlet decay!
  - Equivalent orifices to line sizes!
- Precision control accuracy and instantaneous response!
- Direct acting—eliminates pilot controls!
- Smooth, vibration-free movement!
- Wide range of fluid media: air, gases and liquids!
- Extremely high flows, i.e., 1" unit at 6000 inlet, 1000 outlet provides a flow of 0 to 36,000 scfm!
- Temperature range: —65°F to +250°F!
- End connection available in flanged, pipe, tube or custom!
- Downstream control is internal or downstream sensing!
- Dome loading is external or self-contained!
- Burst pressure four times rated pressure!
- Buna N and nylon diaphragm is optional!
- Extremely maintenance-free!
- Internal parts easily accessible while installed—allowing simple maintenance!
- ***Available for 30-45 day delivery in any material or line size!***

When pressure control problems confront your engineering skill, be sure of dependable performance and maximum control accuracy by specifying APCO's new Servo-Dome Pressure Regulator. We solicit your inquiry.

100-VOLT TRANSISTOR...

New high power type available

Typical Characteristics at 25° C	DT100
Maximum Collector Current	13 amps
Collector Voltage, Emitter Open	100 volts
Saturation Voltage (12 amps)	0.7 volts
Power Dissipation	55 watts
Thermal Gradient from Junction to Mounting Base	1.2° °C/watt
Nominal Base Current I_B (V_{EC} = —2 volts, I_C = —1.2 amp.)	-19 ma
Distortion (Class A_1, 10 watts)	5%

DELCO HIGH POWER TRANSISTORS

The electronics industry asked for a transistor to handle higher voltage—and here it is—Delco Radio's DT100 with maximum collector diode voltage of 100 volts. This is the highest yet, and it paves the way for a wide range of new applications. The new DT100 is an alloy junction germanium PNP transistor—normalized to retain its performance characteristics regardless of age. You can depend on the uniformity, reliability and high current handling capacity of the DT100, just as you have in the past on all of Delco Radio's High Power transistors. Write today for complete engineering data.

SPEED YOUR MISSILE

Precision Welded Stainless Steel,

FROM THE LEADING PRODUCER

Here's how you can stretch your present overloaded engineering and production facilities on missile projects . . .

Use the experienced designers at the Jet Division to develop structures, tanks, and other air-frame parts of your missile . . .

Use the complete facilities of our sheet-metal shop, welding shop, and machine shop to make these missile components . . .

Let our experienced tool designers and skilled press operators produce precision forgings in steel, titanium, and high alloys for the hardware on your missile. These forgings are so accurate in dimension and contour that most finish machining can be eliminated.

Let us send a trained sales engineer to discuss your missile components requirements.

WRITE FOR BOOKLET MR-557

letters

Engineer Has Gripe

To the Editor:

May I pose a question to the rocket and missile industry: How can it be honestly stated that every effort is being bent to achieve the greatest progress in as short a time as possible?

Six years ago I contacted about 15 different companies in the airframe, engine and components fields about free radical applications for propulsion. The few replies I received fell into two basic catagories: 1) new idea, disclosure (give-away), 2) completely uninterested.

In May 1957, I sent out a brochure to 35 companies comprising the major airframe engine and research companies, outlining my approach to free radicals in rocket propulsion. The even fewer replies were the same as in the first case.

In the time between my first and second attempts to broach the field, I have designed, built and tested actual systems which could be flown and which are in existence today. I am now developing a more advanced system, and will test it in the near future.

Dr. Goddard, the man who founded RMI, and myself have one thing in common—we all had to use "backyard" methods.

Rocketry was of minor consequence in Dr. Goddard's day. Today the picture is very different. However, a person with a good idea still must resort to "backyard" methods because industry doesn't have the desire, initiative or vision to make any moves progresswise unless the government foots the bill right from the start.

Right now I wonder if and when I will be faced with challenging some company or corporation because of proprietary rights. All this is not a very good picture for anyone coming up with a valuable idea. I haven't found one company in any of the fields attendant to rocketry who would give me the opportunity to work on free radical propulsion, or even detail my work in order that they may judge for themselves. This includes the company I now work for, a rocket and missile prime contractor.

From my own experience over the past six years, I claim real progress and basic new ideas are government furnished, governmentally used and paid for by the government.

Gregory D. Noyes
8405 Loch Raven Blvd.
Towson 4, Md.

German Eye View

To the Editor:

With reference to a letter by Mr. Russell H. Jones, Jr., "A New Road to Controlled Fusion" (September), may I suggest tuning the cavities of the rocket engine shown for resonance frequency, finding critical absolute size limit and then shaping the whole thing for proper focusing of the shock waves, as shown in the old Hertz-Wiesner patent of Bergmann Ultraschall, 1954.

Perhaps the Russians are already using this principle in the powerplant of their *Sputnik* vehicle, since Hertz was in Russia at one time. What a blow for America's "baby satellites!" I would suggest scrapping the little balls and asking the Ivans how to do a proper job of "satellite throwing."

If you are interested in resonance combustion for fusion reactions in open-space combustion chambers, my partner, Mr. Bernard Olcott, 952 Fifth Ave., New York City, can show you how to boost specific impulse by 100% over what you will ever be able to do with chemical fuels in rocket engines. And all this can be done without the humbug of "sophistication" that the Western World fiddles with so unsuccessfully.

The Ivans know how to simplify things while still decreasing weight. They also know that nothing is happening in the U.S. despite all that security nonsense. This does no good, and actually holds back any real research work and prevents the poor American expert from getting any information from behind the Iron Curtain. America, in turn, knows nothing at all about what the Russians are doing because the Russians keep their mouths shut. They do a job without much fuss about "super-hyper-zip fuels." They just use simple swing laws and cheap fuels, probably solids or "frozen liquids."

Joseph Reder
Heidelberg, Germany

Suggestion Box

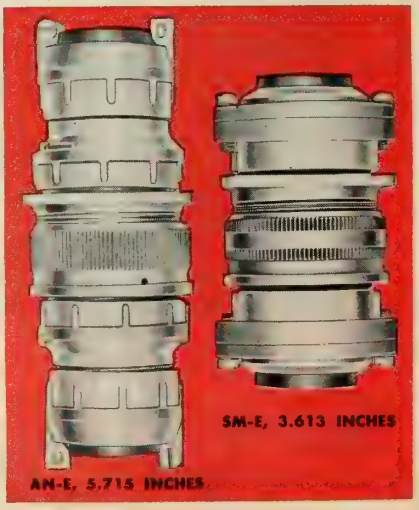
To the Editor:

Your column "Glossarifery" in the October issue is entertaining and light, though lacking technical information. Please continue it. It's enjoyable.

However, I am a trained technical, but non-professional man in the missiles and rockets field. I read and profit from

New Bendix SM-E Connector

(smaller, lighter than AN-E but equally dependable)



Here is the newest in the ever growing family of Bendix* environment resistant connectors. The new SM-E Series (Short "E") will provide the same performance as the standard AN-E connectors, but is shorter, lighter and more easily serviced. Not only does this connector conform to the vibration resistant requirements of the "E" connector in the MIL-C-5015C government specification, but it also provides effective moisture barriers both at the solder well ends and mating surfaces using the full range of wire sizes. Of particular interest to production and maintenance people is the back nut design, which provides a jacking action on the grommet during disassembly, thereby lifting it free of the solder wells. This feature when combined with the new Bendix "slippery rubber" grommets makes easy work of wire threading and grommet travel over the wire bundles.

Available in all standard AN shell sizes and tooled for most of the popular AN configurations.

Write for complete descriptive folder.

*TRADEMARK

Comparison based on size 40 mated assemblies. Space savings for smaller sizes are proportional.

EDISON'S RESISTANCE TEMPERATURE DETECTORS

wide range available for almost any type of use

MODEL 235N90-35
Designed for fast response and high resistance to the corrosive effects of rocket fuels used in guided missiles.
SPECIFICATIONS:
Stem-sensitive.
Useable temperature range —70° to +200°C.
Exponential time constant in agitated waterbath 0.8 second. Maximum hydrostatic pressure on stem: 750 psi at 100°C.
Basic resistance at 0°C = 90 ohms.
Hermetically sealed.

MODEL 242P
This Detector can be operated in live steam or high temperature atmospheres up to 1300°F.
SPECIFICATIONS:
Stem-sensitive.
Useable temperature range —70° to +750°C.
Maximum hydrostatic pressure on stem: 300 psi at 750°C.
Basic resistance at 0°C = 100 ohms.
Hermetically sealed.

MODEL 230N
A general purpose Detector for temperature measurement and control in industrial processes.
SPECIFICATIONS:
Stem-sensitive.
Basic resistance at 0°C = 120 ohms.
Hermetically sealed.

MODEL 166NC
Element is concentrated in tip for sensitivity to surface temperatures in motor bearings, etc.
SPECIFICATIONS:
Tip-sensitive.
Useable temperature range —70° to +300°C.
Basic resistance at 0°C = 120 ohms.

Rugged Edison RTD's are now available in 48 different types for use within indicating, recording, controlling and monitoring equipment. Adaptability of design and materials assures the construction of the best unit for each individual application.

Edison RTD's show marked advantages over conventional methods of resistance thermometry in any one of its many applications including: aircraft, missiles, missile fuels, pumps, motors, or anywhere temperature must be controlled and monitored. For one thing, they do not require signal amplification because they carry a potential of 1.5 volts sufficient to give an immediate indication on any type of instrumentation. For another, they give a time constant of less than ½ second because of their design (electrical bridge type) — a response time much faster than most industrial thermometer bulbs encountered.

The accuracy of metal RTD's is so great that the platinum RTD is the international standard between —190°C and +660°C. Edison RTD's tested years after manufacture show less than ± .05% change from the original calibration.

It will pay you to investigate the advantages of using Edison RTD's in your present or proposed temperature control work. Write for Brochure #3016.

McGRAW EDISON

your periodical. But—a lot of your jargon is above my head.

I offer here a sound suggestion: assist the technician in understanding the scientist.

How about setting aside a few pages each month for an honest to goodness glossary on missiles and rockets terminology. The real Noah Webster type.

I. G. Rooder

Convair Astronautics
San Diego, Calif.

Thank you for your suggestion which is under consideration.—Ed.

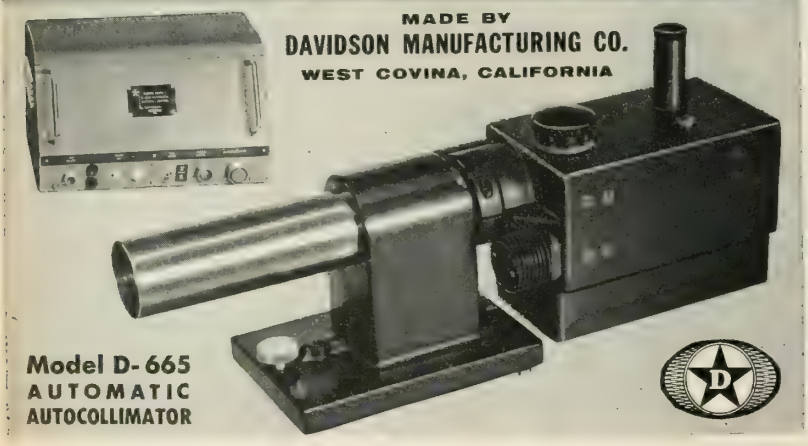
Asks Temperature Data

To the Editor:

In an early issue of MISSILES AND ROCKETS there appeared a chart of "Characteristics of the Earth's Atmosphere." One of the characteristics plotted is temperature, which shows a value of 1200°F beyond an altitude of 200 miles.

We are interested in learning how temperatures could be measured in such a rare atmosphere and what they really represent.

If you are unable to explain the method employed for measuring temperatures in outer space, perhaps you could give us the source of your information so that we could pursue this question further.



Erwin W. Tschudi

697 Thomas Ave.,
Baldwin, L. I., N. Y.

Temperature measurements have not been made at altitudes of 200 miles or above (pre-Sputnik). The values shown on the chart were obtained by extrapolation of known values at the lower altitudes.

One actual method of measuring temperatures at high altitude is by measuring the change in resistance in electric current through a wire.—Ed.

OPTICAL
measurement of angles
AUTOMATICALLY

MADE BY
DAVIDSON MANUFACTURING CO.
WEST COVINA, CALIFORNIA

Model D-665
AUTOMATIC
AUTOCOLLIMATOR

Astounding advances recently made by science and industry have created a need for detection of extremely small angular errors of variations for purposes of measurement, alignment or control.

Davidson has developed this Model D-665 Electronic Autocollimator to make available to industry for the first time a truly fast, accurate and sensitive angular measuring instrument.

Due in part to inherent sensitivity of completely transistorized electronics, and in part to elimination of human errors which characterize use of standard autocollimators, the Model D-665 offers you a much higher increase in sensitivity and greatly decreased response time than you can find in other instruments.

Angular readings appear automatically on a calibrated dial, one revolution of which equals 10 seconds of arc.

On the same shaft as the dial, a potentiometer is mounted, across which operator may put up to 125 volts. A voltage proportional to the measured angle is then obtained between the slider and center tap.

Two jacks are provided, across which appear either a positive or negative voltage, depending upon which direction the reflector is misaligned. They will be useful primarily in problems of alignment, when the dial is held motionless.

Ability to quickly detect exceedingly small angular changes and present them in convenient electrical form makes a Davidson D-665 Automatic Autocollimator the obvious answer for a wide variety of applications, many of which were impossible before this time.

CURRENTLY USED TO ESTABLISH AND HOLD AZIMUTH ALIGNMENT OF GYROSTABILIZED PLATFORMS

Wanted: "Angels" for Launching Bases

To the Editor:

This is a belated response to your proposal in "Missile Miscellany" in July that the American Rocket Society set up a missile launching base for "tomorrow's space-flight engineers, today's amateur missileer . . ." to "static test and fire their hardware."

I assume that this proposal was prompted by the letter from L. F. Megow, of the Rocket Research and Development Society, published in the same issue. Speaking as a member of an "amateur," nonprofessional society, may I suggest to the "manpower-hungry missile industry," that "would foot bill if ARS administered" that there is an organization that would probably jump at the chance. the American Astronautical Federation which has eight member societies.

So large and conservative an organization as that of the ARS must almost necessarily move slowly. Moreover, unless ARS attitude regarding amateurs has changed considerably from a few years ago, I feel rather pessimistic regarding any chance that the ARS would take up such a task in the near future.

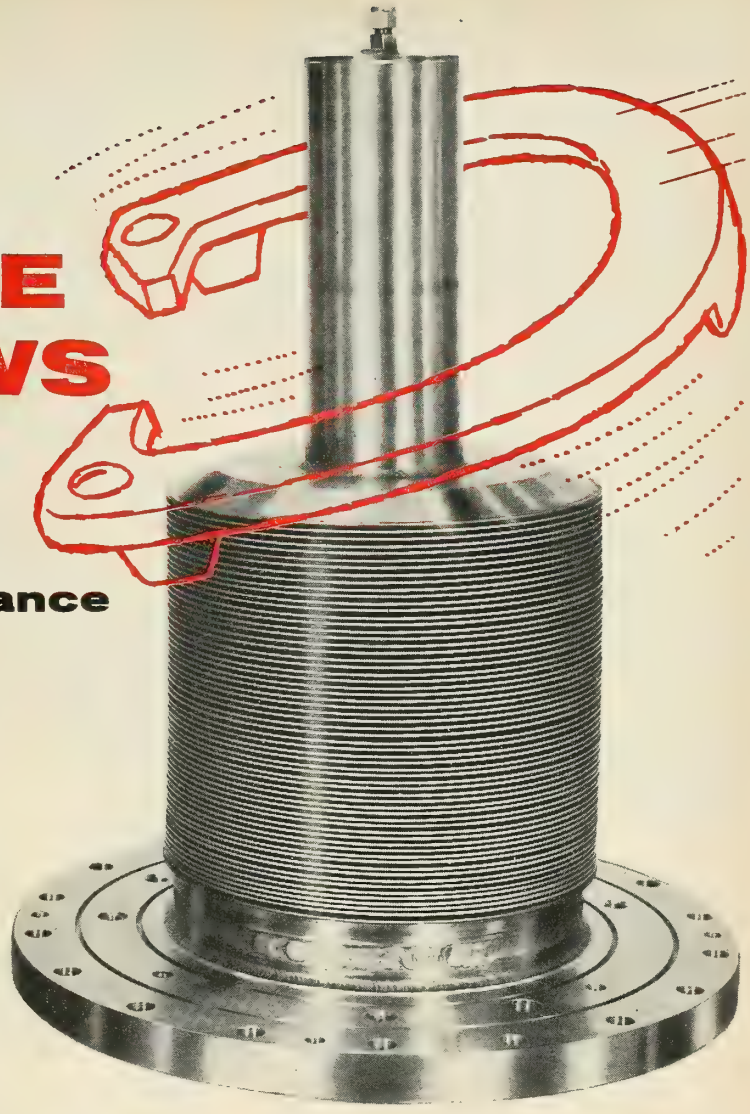
The AAF was formed in 1954, five societies initially joining it. In three years membership expanded to eight societies, not including the Chicago Rocket Society which recently disbanded. These groups constitute almost an astronautic continuum in interests, experimental work, etc.

On the West Coast the Pacific Rocket Society and the Reaction Research Society have jointly purchased, and for over two-and-a-half years have operated, a testing area in the Mojave Desert. The two societies have developed new ideas and successfully launched what is believed to be the first hydrogen peroxide rocket constructed in the United States. There are active groups in Boise, Idaho; Salt Lake City, Utah; and State College. N. M. The Philadelphia Astronautical Society, to which I belong, has done work in liquid and solid propellants, although hampered by lack of adequate facilities. There is a student group at MIT. Cambridge, Mass. In addition, the rather widespread Society for the Advancement of Space Travel, also an AAF member, has headquarters in New Jersey.

I believe that from the framework provided by the member organizations and the national organization through the AAF constitution, a successful missile launching base could be set up, either through expanding existing facilities or establishing new ones. Furthermore, although the membership of each individual society is primarily nonprofessional and amateur, including many young members, professionals do belong.

If anyone is interested, may I advise that they contact the AAF President, Mr. Norris R. Peery of Intermountain Rocket Society, at 1425 Emerson Ave., Salt Lake City 5, Utah, or the AAF Secretary, Mr. Dale R. Smith of the Society for the Advancement of Space Travel, at 3001 Kyle Avenue, Minneapolis 22, Minn.

In ending, I must congratulate you for making such a proposal.



Leon M. S. Slawecki
Corresponding Secretary

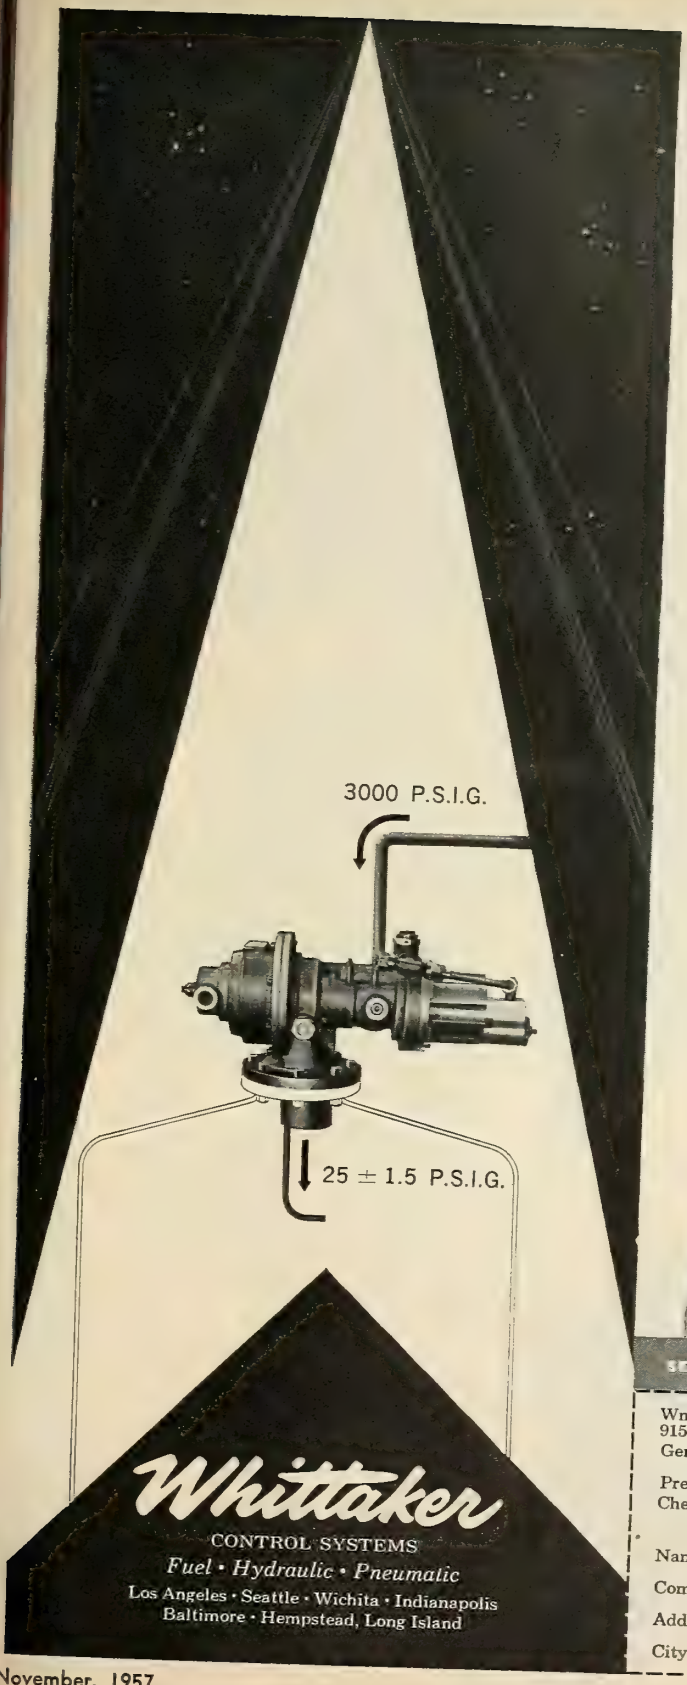
ERCO PROVIDES CRITICAL TRAINING FOR CREWS OF THE KC-135

The recent globe-circling feat of the SAC, B52 in the amazing time of 45 hrs. 19 mins. could have been 5 to 6 hours less — if the all jet KC-135 had been in operation to perform the refueling. Very soon the KC-135 will become fully operational and the crews of these giant 500 mph. tankers will be *fully trained* — thanks to the ERCO Flight Simulator. ERCO — one of the recognized leaders in the field of synthetic training devices was selected to design and build the KC-135 Simulator.

In addition to the KC-135 Floor Based Simulator shown here ERCO has designed, built and delivered more trailerized flight simulators than all other manufacturers combined.



Let us help you with your training problem! Write today to ERCO Dept. MS, Riverdale, Md., for the brochure, "Synthetic Training Devices" and learn how ERCO devices can assist you.

Another missile problem solved by Whittaker:

fuel tank pressure limited to 25 ±1.5 P.S.I.G.

THIS NEW WHITTAKER PRESSURE ACTUATED REGULATING VALVE—designed to regulate and maintain tank pressure at a constant value—reduces high pressure helium or nitrogen to a low pressure and pressurizes fuel and/or oxygen tanks.

With a ¾" tube size it permits the flow of helium to vary from zero to .15 lbs. per second within the control tolerance shown above.

This device includes two reducing stages to assure stable operation, regardless of flow variation, and is controlled by a remotely located sense line. This signals the actual pressure in the low pressure line leading from the unit to the tank.

This unit is now installed in one of the latest IRBM's. It is now in production, and with calibration settings changed to provide any specified request pressures, it can be used for many other applications.

This is only one of the many missile problems of all kinds that Whittaker has solved—and *is* solving every day! Whittaker's wide variety of talents are available to you now.

Performance

TEMPERATURE	Ambient, −65°F to +160°F Fluid, −65°F to ±160°F

DataTape

CEC's 5-752...
The only recorder/reproducer offering complete front access.

standard of the missile range

CEC's MAGNETIC TAPE RECORDER/REPRODUCER

Selected in competitive tests for Air Force and Navy ranges... meets IRIG Specifications...

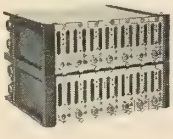
Simplify your data problems... get instantaneous playback with CEC's new 5-752 RECORDER/REPRODUCER SYSTEM. Handles Analog, PDM, and FM signals... provides up to 14 tape tracks for simultaneous recording and reproduction of separate signals on one-inch tape. Features CEC all-metal surface magnetic heads. Constructed to meet MIL-E-4758A. For complete data, contact your nearby CEC field office, or write for Bulletin CEC 1576–X7.

TYPICAL APPLICATIONS

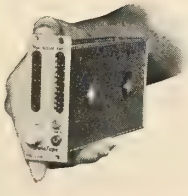
Telemetering from Missiles and aircraft, including FM sub-carrier telemetering • Wind-Tunnel Testing • Jet and Rocket Engine Testing • Studies of Shock and Vibration • Mobile and Stationary Structural Testing: ships, trains, etc. • Static and Dynamic Testing: airframes and components • Sound Measurements: all types of analyses, including sonar, medical research.

DataTape Division

Consolidated Electrodynamics



300 North Sierra Madre Villa, Pasadena 15, California



OFFICES IN PRINCIPAL CITIES THROUGHOUT THE WORLD

For precision in-flight recording, or wherever small size and portability are paramount, DATATAPE RECORDER provides up to 14 tape tracks. This compact recorder provides complete compatibility with the 5-752, guarantees accurate performance under severe environmental conditions (MIL-E-5272A, Proc. 1), and operates at extremely high temperatures to 100°C.

CEC's 1-001 Amplifier Case houses seven record amplifier modules in the smallest package on the market today. Rugged construction provides rigid mounting of modules. Coolant air is provided for operation up to 100°C. Stringent environmental specifications are met without the use of shockmounts.

10-12 oz. Miniature Record Amplifiers feature printed wiring, combination subminiature-tube and transistor circuitry, modular construction, and high-temperature operation to 100°C. Aluminum die-cast packages, 6¼" long by 3¼" high and 1 3/16" wide, provide FM, PDM, and Analog recording.

PYLE *star-line*® CONNECTORS

Assure long-lasting protection of vital connections under a wide range of extreme environmental conditions

Currently establishing itself as a performance leader in the missile systems field, Pyle-Star-Line connectors offer engineers an entirely new line of electrical connectors for universal military and industrial use.

With characteristics of construction and performance never before combined in compact, rugged, lightweight standardized connectors, they exceed NEC requirements and classes A, B, C and E of military specifications MIL C-5015C.

FEATURES

Tough, lightweight shell: Strength comparable to mild steel, yet weighs only ⅓ as much.
Anodic coating: Gives shell toughness of case-hardened steel. Takes up to 1800 volts to penetrate coating.
"Sandwich" insulation: Silicone laminate floats between two rigid discs. Silicone disc absorbs shock, lets contacts align themselves freely; rigid discs impart just the right amount of restraint. Gives all advantages of both flexible and rigid mountings.
Chamber sealing: Silicone insulation disc positively and completely prevents water, gas, moisture or dust from passing into shell.
Wide range of pin and socket configurations: Configurations from 2 to 100 poles available. Within each form size all inserts are interchangeable and reversible.

Environmental Limits of Pyle-Star-Line connectors	
Temperature	—80 F. to 225 F.
Pressure	300 PSI External, 200 PSI Internal
Chemical Resistance	Most acids, most alkalis, oil
Corrosion Resistance	Salt Spray: 300 days without failure
Dust Resistance	Exceed requirements of MIL C-5015C
Shock Resistance	50G Minimum
Vibration	Exceed 20G to Method II of Mil C-5015C
Humidity & Moisture Resistance	Exceed Class E. Spec. of Mil C-5015C
Air Leakage	Meet Class E Spec. of Mil C-5015C

Write today for complete specifications.

Chlorine Trifluoride (ClF_3)
Bromine Pentafluoride (BrF_5)

GENERAL CHEMICAL – your prime source for Fluorine and its compounds

As America's primary producer of elemental fluorine, halogen fluorides and other fluorine compounds, General Chemical is geared to supply virtually any need—from tonnage requirements of fluorine to research or commercial quantities of many derivatives.

Of particular interest to you may be the ready availability of fluorine in *liquid* form. A break-through in fluorine technology pioneered by General Chemical now makes it possible for us to ship liquid fluorine in tonnage quantities . . . and for you to use it with greater safety and economy than ever before.

A special technical bulletin on fluorine (both gas and liquid) covering physical properties, storage and handling is available on request. Further information on it or other fluorine compounds of interest to you is available from any company office listed below.

• • •

General Chemical is also a major supplier of red and white fuming Nitric Acid so important in rocketry development programs. Complete data on request.

PRECISION FORGINGS By WYMAN-GORDON

Precision . . . close tolerance . . . low-draft . . . no-draft — these are relative terms and considerable confusion has been created because they have been loosely used. Close tolerances on large forgings have been pioneered by Wyman-Gordon over the years. The degree of precision which is practical now becomes a question of economics.

The forgings illustrated are typical of Wyman-Gordon close tolerance forgings that have been produced in quantity. In solving problems of tolerances, design and metallurgical quality, there is no substitute for Wyman-Gordon experience.

Russia's Moon Rocket Program

Soviets Leap Ahead Again
Skip Bomber In Test Stage

By Erik Bergaust

BARCELONA—Details of Russia's moon rocket program were revealed to MISSILES & ROCKETS during the Eighth Congress of the International Astronautical Federation here. The expected news of Russia's technological victories in space flight science indicates the first lunar rocket may hit the moon before this issue of m/r goes to press. Furthermore, Dr. Leonid Sedov has confirmed to m/r that Russia's second satellite will carry a live passenger! A dog will be the first living creature to enter into an orbit around the earth. Dr. Sedov did not give a fixed date for this event but said it should occur about "the end of the month."*

The Moon is Next

This reporter learned exclusively from members of the Russian delegation to the IAF meeting that the moon comes next. When asked whether they have the hardware available or if they are building new launching equipment for any of their moon rockets, the Russians smiled and said Russia's satellite and moon rocket scientists are not concerned with this. "We just ask the military for the rockets—and they provide them. That's all." The Russian delegates were Academecian Leonid I. Sedov, chairman; Dr. Alla T. Massevich; Dr. Lydia Kurnasova; and A. Karpenko, secretary of the Commission on Astronautics, Academy of Sciences.

The immense significance of the above statement lies in the fact the Russians have an almost unlimited supply of workable, big liquid rockets available for space flight. Their T-4 engine, built for their manned skip-glide bomber vehicle which is now being test flown, yields a thrust of 820,000 pounds. When asked whether this engine will be used to propel their first moon rocket aloft, Dr. Sedov merely smiled and threw has arms out as if he couldn't care less what kind of engines would be used. (Dr. Sedov, at the seventh IAF congress in Rome last year, revealed exclusively to this reporter that Russia was working on several different kinds of atomic-powered rockets. The story appeared in m/r October, 1956.)

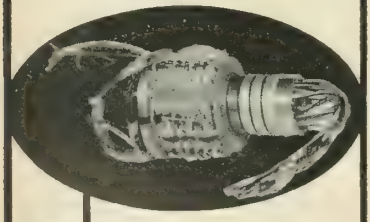
The race to the moon is on and Russia probably will win it. First comes the "direct hit approach"—with a little bit of luck, the Russians will do it.

Then, and this one is possibly more significant, comes the circumlunar vehicle. Eventually, this kind of rocket will carry cameras aboard.

Dr. Sedov—the great hero of the congress—also had some advice to Americans. He talked rather sarcastically about American interservice missile rivalry. When asked by an American delegate what he would have done after the first *Sputnik*, had he been an American, he said: "I would do something better and more significant." Of course, the American delegate agreed. But the sad fact remains—America is too far behind Russia to be able to match her in astronautics. So far behind, in fact, it is almost pathetic.

Moon Rocket Details

Dr. Sedov and his teammates were all smiles throughout the conference. They were joking and laughing happily, almost victoriously. And they most certainly had reason. Sedov told Dr. Fred Singer of Maryland University he would be happy to take one of the U.S. professor's cosmic ray counters aboard one of the next *Sputniks* since, apparently, Dr. S. F. Singer must wait a long time before he can have his equipment carried aloft in any American satellite..



The Russian delegation was approached by many newsmen asking

**NOTE: m/r went to press at the time Russia announced* Sputnik *II.*

looking for slip rings?

questions about the Red missile program. But no comment was given by any of the Russians. As far as space flight is concerned, however, they were not afraid to talk.

From our conversations with the Red delegation, we can conclude the following facts about their moon rocket program:

1) The first Russian moon rocket will be launched just about the time this issue of *m/r* goes to press. If the attempt is successful, it will be advertised by the Russians as their big propaganda blow for the 40th anniversary of the Communist Revolution. If the rocket fails, the Reds will have some other stunt, such as flying their first atomic airplane, or a similar feat.

2) The first moon rocket may carry a payload of approximately 500 pounds and will be designed to either hit the moon or enter into an orbit around the moon. A radio transmitter will be aboard.

Reversed Thrust To Be Employed

3) The second type of lunar vehicle will be designed to retard its fall toward the moon by braking or reversed-thrust rockets and will plant itself and its transmitter intact on the moon's surface. The transmitter will send back to earth information on temperatures on the moon's surface.

4) The next type of moon rocket will carry television-type camera equipment that will relay back to earth close-ups of the moon's surface, possibly of the other side of the moon, never seen by man.

5) The fourth type might carry animals or even man—if the previous rockets have been successful and if the information gathered has been satisfactory enough to encourage manned trips into space. All this will happen within a few years.

The interesting point, of course, is that this sequence of approach has been discussed in this country and all over the world as the logical one for this kind of scientific-military adventure. The important thing is that the Russians are doing something about it and admit they are working hard to achieve these goals.

Man On the Moon in a Few Years

When this reporter asked Dr. Sedov whether he anticipated that man would establish an observation post on the moon in this century, he said: "Of course; at the rate we are progressing now, it shouldn't take too long." It's a sad thing to think about how Dr. Wernher von Braun outlined such projects for the U.S. government 10 years

Dr. Leonid I. Sedov, Soviet space satellite expert and well-known scientist, was the big hero at the Barcelona IAF meeting. Here he is trying to convince IAF president-elect Andy Haley the Russians will beat us to the moon.

And here he is being congratulated by the dean of aeronautics, Professor Theodore von Karman. The toasts to the Russians and their success were many. This one was in champagne. Sedov seemed to appreciate it.

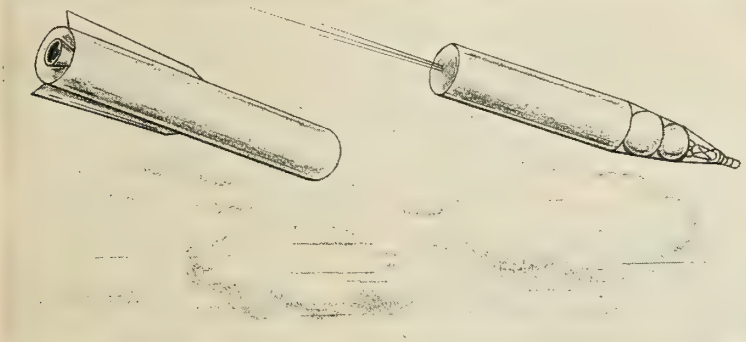
During the technical sessions Sedov discussed scientific problems freely with delegates from many countries. Here he is offering Dr. S. Fred Singer of Maryland U. an explanation of some Soviet theory on cosmic rays.

Sedov enjoyed the social affairs and was intrigued by the Spanish folk dance festival put on for the IAF delegates. He is seen with spacemen Rolf Engel, center, and Redstone's Dr. H. H. Koelle. They, too, had a good time.

ago—and was laughed at and was almost thrown out the door of the Pentagon conference room.

Dozens and Dozens of Satellites

Members of the Red delegation confirmed that Russia would launch "many" satellites during the IGY—and after the IGY. When asked how many would be sent aloft during the IGY, the answers ranged from "a handful" to "about a dozen," which means that the Russians will be launching satellites of various kinds at a rate of almost one every five weeks. (So far they have done considerably better than that.)



Sedov indicated that Russia's moon rockets and "other space vehicles" would be launched independently of their IGY satellites. He offered a remarkable comment in this connection: "One should not be so overwhelmed about these things; like America, we committed ourselves to launch a series of satellites during the International Geophysical Year. We're just doing what we said we would."

nated the technical session with some 25 papers (only a few of which were good), against two or three papers from any other country.

The press was disgusted, confused and frustrated over the complete lack of preprints of papers, press facilities, translations and liaison. Official press conferences were few and handled so poorly that many newsmen walked out in the middle of them. Furthermore, anyone who felt like giving a statement to the press arranged his own press conference. The Americans were great at this. Of course, the Russians did not hold any press conference. To quote Dr. Theodore von Karman: "The Americans are talkers; the Russians are doers." Dr. von Karman also criticized the quality of many of the American papers.

Durant Opposes U.S. Vice President

But there's hope for the IAF. Andy Haley was elected president for 1958, and he has promised a hectic, progressive year for the organization. Already he is busy at work planning the next congress, to be held in The Netherlands. The 1959 congress probably will be held in Moscow; 1960 in Stockholm, and 1961 in Washington, D.C.

Russian drawing of rocket vehicle designed to land on the moon's surface, employing reversed thrust rocket in the nose for braking.

Inferior IAF Congress

IAF's new president, Washington, D. C. attorney and well-known space lawyer Andrew G. Haley, had some discussion with Sedov on the subject of space law and jurisdictional aspects of moon exploration, but Sedov did not commit himself in terms of whether the Russians would claim ownership of the moon once they've planted their flag there.

Had it not been for the launching of the first *Sputnik* and the presence of the four-man Russian delegation, the Eighth Congress of the International Astronautical Federation would have been a complete flop.

The meeting was almost completely disorganized. In spite of beautiful Spain and its hospitality, in spite of the Spanish host society's honest efforts, the meeting was amateurish from beginning to end. Americans dominated the technical session with some 25 papers (only a few of which were good), against two or three papers from any other country.

Mr. Haley suggested current American Rocket Society President Robert C. Truax for IAF vice president for 1958, but Frederick C. Durant III apparently pursuaded Haley to reconsider. Haley withdrew his proposal. Thereafter the following astronauts were elected vice presidents: Acad. L. I. Sedov (USSR), Prof. Zarankiewicz (Poland), Dr. L. R. Shepherd (U.K.), Ing. A. Hjertstrand (Sweden), Dr. J. M. J. Kooy (Holland) and Prof. T. M. Tabanera (Argentina).

Asiatic flu took its toll during the Congress. Brig. Gen. Toftoy, Rolf Engel and an R.A.E. representative were each out for a few days with high fever. Sedov managed to carry through until Saturday before he, too, succumbed.

Air Force Infrared measuring program chooses Barnes instruments

University of Michigan scientists using Barnes Far Infrared Mobile Laboratory on Pikes Peak.

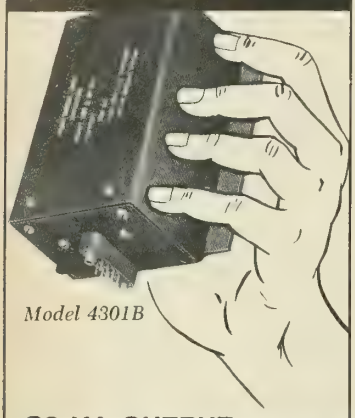
The majority of participating groups in the Air Force's critical pioneering study on infrared radiation of background and targets selected Barnes infrared measuring equipment.

This equipment included Infrared Radiometers, OptiTherm® Far Infrared Cameras and low and high temperature Infrared Reference Sources. Barnes Engineering is the only commercial source for completely integrated radiation detecting and measuring instruments of this kind.

The standard line of proven field and laboratory infrared equipment offered by Barnes includes:

- Infrared Radiation Measuring Equipment
- Infrared Radiation Sources
- Thermistor Infrared Detectors
- Building Blocks for Infrared Systems

Advances in radiation detection and remote temperature measurement owe much to developments that originated with the Infrared Division at Barnes Engineering. They are equipped and staffed to develop your infrared systems.



If you are thinking of using infrared, write for complete information on the integrated line of Barnes OptiTherm infrared radiometers, sources, detectors and components.

BARNES ENGINEERING COMPANY

TRANSISTOR INVERTER

Model 4301B

• 30 VA OUTPUT

MISSILES AND AIRCRAFT

The Model 4301B is a typical Varo transistor inverter. Other models with higher power output, higher frequency output, and ac input are available for systems engineering. Custom designs can be produced for special applications.

SPECIFICATIONS

Output:	*30 V.A. 1Φ*
Frequency:	*400 cps ± 0.1%*
Voltage:	*115 V ±10%*
Harmonics:	*10% max.*
Input:	*26 to 29 VDC*
Temperature:	*−55°F to +160°F*
Vibration:	*10g to 1000 cps*
Size:	*29 cu. in.*
Weight:	*2 lb.*

Varo transistor inverters are designed to operate gyros in guidance systems. They are frequency regulated by a Varo bimetal tuning fork, voltage regulated by a zener diode reference, and produce a sine wave output through Class B amplification.

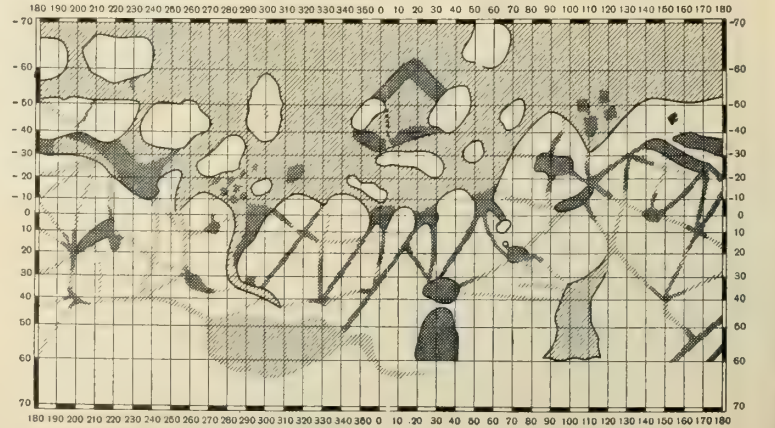
How Accurately Was *Sputnik* Launched?

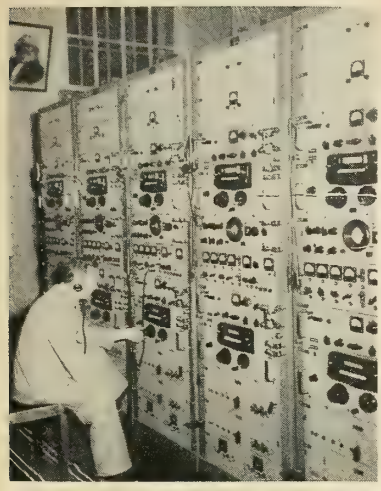
To find out, the editors of m/r consulted Dr. S. Fred Singer, who made accuracy and lifetime calculations for Project *Mouse* in 1954. Here is what he said:



"We are not sure of the release altitude of the Russian satellite (burn-out altitude of the last stage), but we can be sure that it was not less than 200 miles. For a lower release altitude any small error in release angle is fatal because of the dense lower atmosphere. Higher altitudes of release are desired, since they give more latitude against guidance errors.

"With *Sputnik*'s reported orbit, initial perigee and apogee 140 and 560 miles respectively, I get the following results:

Launch Altitude Miles	Velocity Error	Release Angle Error
375	−0.2%	2.8°
190	+1.8%	1.75°
140	+2.6%	0.0



"The release altitudes are chosen to bracket the probable value. The lower altitude is most unlikely due to reasons stated above. The angular error in these calculations is astonishingly large. It's sufficiently good enough for a satellite but not good enough for an ICBM.

"The answer must be that their ICBM guidance system is too heavy for the third stage of their satellite rocket. It is doubtful if they could hit the moon with this kind of guidance without a great deal of luck. Thus, *Sputnik* doesn't necessarily prove they have ICBM capabilities, only that they have a large rocket. On the other hand by itself it doesn't prove they don't have an ICBM either."

Recently released map of Mars published by Russian astronomers.

Super Control Center for Soviet Satellites

Moscow has a super control center for tracking of satellites. Permanent observation of the *sputniki* is conducted at various radio stations, such as the one shown in the above picture. The control center and the radio stations are operated by the Ministry of Communications of the U.S.S.R. near Moscow, under direct supervision of the Commission on Interplanetary Travel. The Soviets have informed us the engineer shown here is Ivan Pryzhkov—eagerly listening to the signals from *Sputnik* II.

Reds Build Huge "Brains" for Nuclear Calculations

The Soviets have built a machine that "multiplies 15-digit numbers at the rate of 500,000 actions per second, and adds such numbers at the rate of two million actions per second."

A problem in nuclear calculations which only a year ago would have required six months' work can now be done on the new computer in about one day.

The Soviet Academy of Sciences has a special computing center in Moscow, whose chief, Academician A. A. Dorodnitsyn, said recently that in one year his center's best computer did the work that would have required the efforts of 10,000 human calculators laboring not less than 20 years. This electronic computer takes less than 20 hours to solve problems "requiring 250 million actions in arithmetic." The computer is serviced by a team of only two engineers and one technician per shift.

Besides Moscow, main Soviet centers of electronic-computer improvement, production, functioning, and engineer training are Penza in east European Russia; Erevan, capital of Soviet Armenia; and Kiev, capital of the Soviet Ukraine.

The Kiev computing center is one of the most recently established in the Soviet Union. The giant computer, now being built for it, is already in partial operation. In one eight-hour working day it performs "the work that can hardly be completed by 100 experienced mathematicians laboring 10 years."

Red Star Reprints American Missile Map

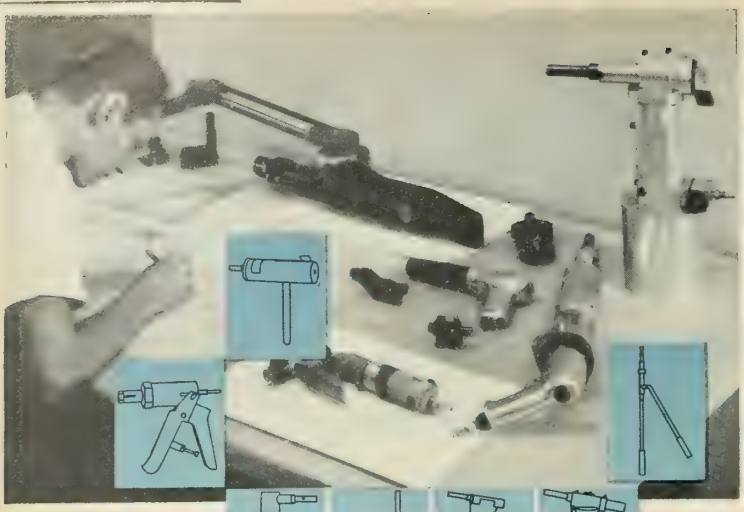
Referring to it as "forced fear" the Soviet army newspaper *Red Star* recently reprinted a map originally used by U.S. News & World Report.

Showing the United States under a circle of Soviet ICBMs, the map is entitled "Russia Could Reach Target in the U.S." The map was cited as more evidence of American warmongering.

Moscow Shocked by Guided-Missile Toys

Under the banner headline, "Imperialism Breeds Murderers and Violators," the Moscow Komsomolskaya Pravda accuses the U.S. of deliberate encouragement of the sale of guided-missile toys.

"On the counters of American toy stores it is now hard to find the heroes of old fairy tales—those good-natured teddybears, those shy long-eared rabbits," the Red newspaper charges. Instead, U.S. customers have to buy all sorts of miniature weapons, particularly "atom bombs and guided missiles which fly, shoot, explode, destroy toy cities, and kill toy people."



The Russian article is accompanied by a picture showing an American boy, who, the Moscow editor explains, is a seven-year-old lad named Eddie, "full of happiness because he has an atom gun and a guided-missile installation which shoot and explode like the real thing."

Cushioning Cosmic Drop Attempted by Reds

Measures to protect a person "passing from airless space to the lower, solid layers of the atmosphere" are now being worked out by Soviet experts in cosmic medicine. This was announced at a recent Moscow meeting by Professor P. K. Isakov, a Stalin Prize winner and chairman of the Soviet State Committee on Cosmic Medicine.

Prototypes of new special tools for installing Cherry Blind Rivets and Lockbolts are shown in the Cherry Research and Development Department.

Special Tools

for building tomorrow's aircraft being developed today by Cherry research

Higher speeds and operating temperatures of aircraft, missiles and rockets of the future demand fasteners with greater resistance to the stresses imposed upon them than ever before.

Installation of these high strength Cherry Rivets and Lockbolts* will require new special tools such as those now in the development stage in the Cherry Research and Development Department.

This activity—anticipating the needs of the aircraft industry and the military—is an old story with Cherry. For years, Cherry engineers and technicians have devoted themselves to a single objective—the production of better aircraft fasteners and the tools for installing them.

Tools for solving specific problems—tools for efficient production fastening—all are developed and produced in the Cherry plant at Santa Ana which is devoted exclusively to the production of fastening equipment for the aircraft industry.

For information on the most efficient fastening methods for your operation—write Townsend Company, Cherry Rivet Division, P. O. Box 2157-Z, Santa Ana, California.

Reds Reveal Scientific Plans

The Soviets now claim they have the world's largest installation "to capture and study broad lines of cosmic rays" as these particles of "ultra-high energies, messengers of cosmic spaces, penetrate the earth's atmosphere." According to *Komsomolskaya Pravda* the "unique machine," installed in the Lenin Hills of Moscow, has "five thousand registers."

Izvestia reveals that the Riga "Hydrometpribor," on Latvia's Baltic shore, is a leading Soviet factory producing precise instruments in the field of physics. Recently the Riga plant has made 100,000 of the instruments required for the Russian part of the International Geophysical Year. The scientists of the Moscow University are collaborating with the engineers and designers of the Riga plant in creating some of these instruments.

Russian LOZ Work Dates Back to '50

As early as 1950, the USSR had available pure, liquid ozone for research and limited development. Initial work on LOZ was begun around 1947 at several universities in the Moscow area, notably the University of Moscow and M. V. Lomonosov State University. By 1951 they had succeeded in stabilizing and producing enough LOZ so that it could be used by other personnel and for other basic work. For example, for some five years, the Russians have been using LOZ in an attempt to synthesize hydrogen superperoxide—H_2O_4. This latter compound, arrived at via LOZ and bombardment techniques, may in reality be a polymer of HO_2 (perhydroxyl). Key people in the Soviet super-oxidant projects are: A. P. Purmal, N. I. Kobozev, L. I. Nekarsov, and E. N. Eremin. Purmal's work is being carried out at the D. I. Mendelev Chemical Technology Institute at Moscow.

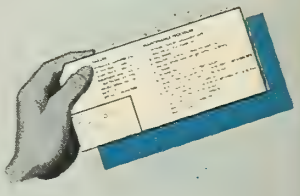
Soviets Build Bolometers At Academy of Sciences

The Institute of Physics at the Soviet Ukrainian Academy of Sciences announces that it has successfully tested and begun mass production of an extrasensitive bolometer "to measure the temperatures of revolving parts of machinery and to help in astronomical and allied researches." The apparatus is claimed to register such "minute changes in heat as one-millionth of a degree."

R

RAPID

RACE* eliminates slow, time-consuming manual tests by electronically checking complete weapon system such as missile or aircraft. Operating on initial assumption that system is functioning properly, RACE speeds through primary test of over-all system or major sub-systems. If fault exists, RACE signals "no-go", then isolates fault through secondary tests. Complete job is done in only minutes.



1008 HOURS

A

AUTOMATIC

Advanced design eliminates chance of human error by use of standard computer techniques of programming, memory, digital and analog comparison. Signal generators include electrical, electronic, hydraulic and pneumatic signal sources, as required to actuate circuits or simulate system signals for comparison with standard reference signals.

1009 HOURS

C

CHECKOUT

RACE not only pinpoints weapon defect —it also flashes on control console screen location, name of faulty unit, down-time involved, location of spare, type of technical work required, system power and arming conditions for safe repair. Simultaneously, punched maintenance card with complete, detailed instructions for repair is automatically ejected.

1025 HOURS

E

EQUIPMENT

Design flexibility adapts RACE for use at operational sites in pre-launch and pre-flight check-out, for in-flight testing, for maintenance areas and overhaul depots. Current and future applications include missile data reduction stations, shipborne and airborne radar, automatic navigation systems, aerial reconnaissance systems, ground fire control systems and missile guidance systems.

1030 HOURS

*T.M.

Today Sperry is working closely with all branches of the military—Army, Navy and Air Force – in applying RACE to major weapon and defense systems. For more information on RACE, write our Microwave Electronics Division.

Avco today

Avco's Lycoming raises the ceiling for business

Today, business is climbing, literally, to new heights. Part of the story is the executive mobility made possible by a growing reliance on faster, more powerful twin-engine corporate and utility aircraft.

Business got its first power plants from Lycoming. Today, more Lycoming engines roar in twin-engine executive aircraft than any other engines in the world. And Lycoming's engineers are developing new, light, supercharged engines and gas turbines . . . to help shrink distances for America's business.

THIS IS AVCO

Avco today is a diversified organization whose products include aircraft power plants and structures, electronics for defense and industry, and specialized home and farm equipment. Avco's divisions and subsidiaries are:

Lycoming—aviation, marine and industri power plants . . . Crosley—electronics and aircraft structures . . . American Kitchens . . . New Idea and Ezee Flow—specialized farm equipment . . . Research and Advanced Development . . . Crosley Broadcasting Corporation . . . Moffats Limited (Canada)—commercial gas and heating equipment.

Scientists interested in unusual opportunit for advancement can grow with Avco.

There Wasn't a "Trick" to be Heard

World reaction to *Sputnik* II was like that to its predecessor but with these differences: nobody called it a "trick," and there were loud wails from dog lovers.

Renewed cries went up for a special session of Congress and a speedup of our missile program.

• Sen. Henry M. Jackson (D-Wash.) called for a missile "czar" and the launching of a "bold program" for increasing scientific and engineering training. "Moscow is now in the process of taking away America's historic trump card—its industrial and scientific supremacy," he said.

• Sen. Allen J. Ellender (D-La.) said it showed "the West has had its head in the sand too long," but that we are not trailing the Russians in the missile field. "They just beat us to the punch."

• In Japan, Masashi Miyaji, head of the Tokyo Astronomical Observatory, objected that the Russians did not announce the launching in advance.

• A group of scientists at Stanford University, Palo Alto, predicted that *Sputnik* II may continue to orbit for "100 years or more."

• Two reactions from top Defense people when asked if we would now speed up our missile program: Gen. Nathan F. Twining, chairman of the Joint Chief of Staffs, said, "What do you think?" Defense Secretary Neil H. McElroy said it would have no great effect. "We already are in a pressure program."

• Mrs. Irene Enzinger, founder of the Orphans of the Storm Animal Shelter, in Deerfield, Ill., spoke up for shocked canimaniacs all over the world, condemned such use of dogs as "disgraceful and cowardly," since the dogs "have no chance to speak up as to whether they want to be used in these experiments."

Excellent Progress at Martin Orlando

The first production *Lacrosse* missile manufactured at The Martin Company's new Orlando, Fla. facility, has been delivered to the Army less than 11 months since the start of construction on the plant.

This is indicative of the outstanding progress that is being made by The Martin Co. in placing their latest missile plant in full operation. The plant, being built in a pine forest nine miles southwest of downtown Orlando, will be completed this year. Installation of machinery was begun on Oct. 1. The first contingent of personnel will begin moving in Dec. 1.

The Martin Co. engineered a remarkable logistical operation in the rapid move of *Lacrosse* manufacturing from Baltimore to Orlando. A temporary building for *Lacrosse* manufacturing was leased in late October last year. A nucleus of manufacturing personnel was moved in that month. Machinery move was completed by February. One month later, the Army accepted the first *Lacrosse* missile produced in Orlando.

The company-owned plant will also produce the air-to-surface *Bull Pup* for the Air Force.

Outstanding rocket propulsion scientists Frau Irene Bredt-Sänger and husband Dr. Eugen Sänger who believe the Russians have been activating their skip-glide bomber project and that their T-4 engine is in production. The T-4 engine yields 820,000 pounds thrust and might have been used to launch SPUTNIK II.

Model #545-250 as shown. (Outside dimensions 65" x 54½" x 65". Interior free field dimensions 33" x 22" x 33") is designed for a low frequency cut-off of 250 cps.

AN-ECK-OIC® Chambers are used for:

- determining acoustical characteristics of radio, TV, audio equipment;
- analysis of noise in mechanical and electrical equipment such as air-conditioners, refrigerators, household appliances, office machinery, motors, transformers;
- free field calibrations of microphones, loudspeakers, hearing aids, etc.;
- psycho-acoustic studies;
- sound power level measurements and other applications.

Portable Chambers are fabricated with outside and interior free field dimensions to suit customer requirements.

Low frequency cut-off in portable chambers down to 150 cps.

Low frequency cut-off in built-in chambers down to 50 cps.

Shooting Dogs into Space Old Hat to Russians

The Russian decision to use *Kudryavka (Curly)*, the dog, as the first warm-blooded space traveller was based on many years of successful experiments with dog "guinea pigs."

Several Russian animals, particularly dogs, have made high-altitude flights in rocket vehicles. A recent flight attained an altitude of 130 miles. The dogs were returned to earth by parachute and, according to Soviet scientists, survived the flights without mishap.

Apparently Russia was not prepared for the onslaught of world-wide denunciation of the experiment. Early

Russian space dog and rocket gear.

reports stated that *Kudryavka's* space cabin would be ejected from *Sputnik II* and would be returned to the earth by undisclosed means.

A. A. Blagonravav, top Soviet satellite scientist, has since disclosed that recovery of the capsule will not be possible. Another scientist has stated further that *Kudryavka* is not expected to live for more than 10 days. This may indicate that the dog's oxygen or water

Dog landing safely in parachute container.

supply will be depleted by that time.

Meanwhile, some U.S. officials involved in IRBM and ICBM nose cone development, have expressed the conviction that recovery of the capsule is possible if Russian developments in this field are on a par with U.S. developments.

The velocity of the satellite or capsule would have to be reduced at least 60 per cent before it reached the denser atmosphere below the 20-mile level.

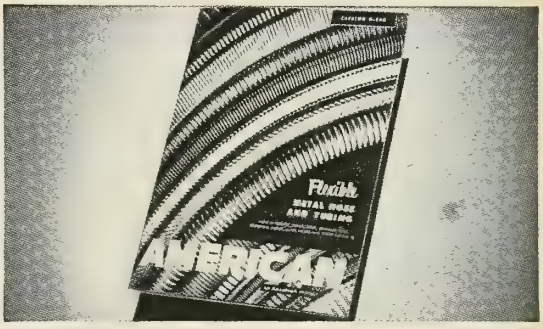
Research Rocket Flights Made off Cape Charles

ABOARD USS *LAUNCHER*—A series of research rocket flights are being made from the deck of this converted LCT (Landing Craft Tank). As part of a University of Maryland program under the direction of Dr. S. Fred Singer, eight high-altitude rocket flights are now in process with the object to obtain additional data about conditions in the ionosphere.

The program includes four flights by *Terrapin* (designed by the University of Maryland and manufactured by Republic Aviation) and four flights by *Oriole*, designed and manufactured at the University of Maryland. Experiments being conducted include the release of sodium vapor at 80-to-120-mile altitudes, the release of nitric oxide and the creation of artificial meteors. There will also be one shot of a flash bomb by the *Oriole*, in order to pinpoint its trajectory and thus, altitude.

The *Oriole* is a new "university research rocket," designed by Richard Bettinger, a graduate student at the University of Maryland. Using an Army *Loki* as a booster, *Oriole* is so simple that it's revolutionary. Depending on whether its "sting" is three-quarter inch or one-and-a-quarter inches in diameter, it will take a scientific payload to 80 or 120 miles altitude. Separating from the booster at the end of its 0.8-second burning time, the finless, unflared sting coasts to its peak altitude. With the *Loki* is provided free by the Army, the whole unit costs less than $300, less payload. It uses a standard *Loki* spin launcher adapted to the light-weight breakdown *Terrapin* launcher.



NAA Super Rockets for Mars and Venus

We don't lack ideas in this country when it comes to space flight. We just don't do much about realizing them. Here, for example, are a couple of North American artist's conceptions of solid-liquid and liquid (right) rocket vehicles designed for travel to Mars and Venus. The rockets are based upon available hardware. How about it, Mr. McElroy?

Jupiter is Accurate

The sixth *Jupiter* took off on a 1500 mile firing recently to fall within two and one-half miles of its ten mile target center.

New catalog simplifies selection and ordering of flexible metal hose and tubing

Describes basic types: corrugated, formed stripwound. Suggests correct installation methods. Information on: dimensions, weights, bending diameters, pressures, etc. Description and suggested uses of varied types in many metals: bronze, brass, aluminum, Monel, steel and stainless steel. Specifications on end fittings. Write for Catalog G-560. The American Brass Company, American Metal Hose Division, Waterbury 20, Conn. Cryostat at Lockheed To Make Liquid Helium

Lockheed is installing a cryostat for the production of liquid helium at the research laboratories of its missile systems division in Palo Alto. Prime purpose for the super-refrigerator that can produce temperatures cold enough to freeze moving molecules in their tracks, is Lockheed's own research, but it will also make the liquid helium commercially available to other scientific groups.

Eight San Francisco peninsula firms have already expressed a need for 400 liters per month. Capacity of the Lockheed cryostat will be about 1000 liters a month. Lockheed's missile division is studying the use of liquid helium as a low-temperature bath for electronic and other devices, and it also is conducting studies in certain unusual properties of the helium itself.

More Money for *Jupiter?*

HUNTSVILLE, Ala.—A supplemental appropriation, perhaps as much as $75 million, is believed to be wending its way through the Pentagon for the *Jupiter* program. Intended for accelerated development and testing of the IRBM, the money is presumably coming from Department of Defense funds to continue financing *Jupiter* when the current contingent fund of some $35 million runs out. This is accompanied

To the ENGINEER of high ability

The most important engineering assignments are now being placed with companies which can point to superior accomplishments not only in research and development, but in production of the end items. Because of this, engineers interested in aircraft and missile components and systems will find outstanding opportunities at the Garrett Corporation. Our prime areas of operation include the following:

air-conditioning

pressurization

heat transfer and cryogenics

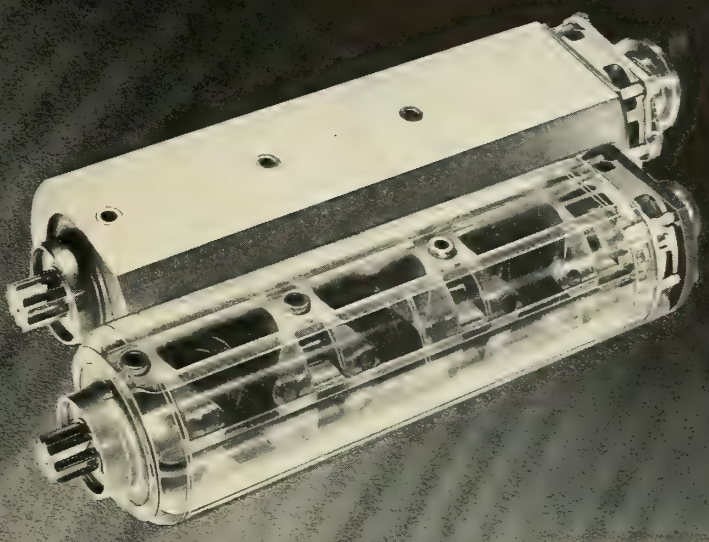
pneumatic valves and controls

system electronics, computers and flight instruments

gas turbine engines and turbine motors

The Garrett Corporation also has made important advances in prime engine development and in design of turbochargers and other industrial products.

Our engineers work on the very frontiers of present day scientific knowledge. We need your creative talents and offer you the opportunity to progress by making full use of your scientific ability. Positions are now open for mechanical engineers ... mathematicians ... specialists in engineering mechanics ... electrical engineers ... electronics engineers.



For further information regarding opportunities in the Los Angeles, Phoenix and New York areas, write today, including a resume of your education and experience. Address Mr. G. D. Bradley

Power Actuation at +1000°F

AiResearch Cam-Piston Air Motors function with complete reliability at extreme temperatures—require no conventional lubrication or cooling

SPECIFICATIONS

Model Numbers	CM-710 *(illustrated)	CM-350	CM-160
Total Length (in.)	13.3	11.8	9.7
Min. Height (in.)	3.1	2.9	2.5
Max. Dia. Envelope (in.)	4.0	3.2	2.5
Weight (lb.)	22	15.5	7.5
Output at 200 psig supply pressure and 1200 rpm (hp)	18.5	9.1	4.2
Starting Torque at 200 psig supply pressure (inch-pounds)	1800	890	400

Here are air motors that operate dependably far beyond the temperature limits of electronic and hydraulic units.

Using bleed air as a source of energy, the output of the air motor is almost linear with inlet pressure, allowing maximum efficiency through a wide range of operating conditions. High horsepower and torque to weight ratios are obtained by displacement volume per revolution exceeding the overall volume of the motor.

Motor acceleration is extremely fast — less than .05 second in most applications. Low rotating speeds — from 100 rpm to 2500 rpm — make gear reduction unnecessary and minimize problems of over-speed control, rotational stresses and wear.

Flexibility of the basic design allows for a wide range of motor sizes — from less than 1 hp up to 300 hp — depending on the available pressure supply. Length vs. diameter shape can be changed by varying the number of pistons and/or the piston diameter and stroke.

When coupled with a ball screw which may retract within the full length of the motor shaft, the cam-piston air motor has wide application as a compact, high-performance linear actuator in high temperature pneumatic power control systems.

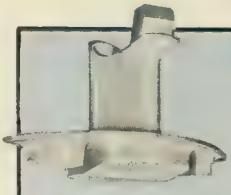
Don't be grounded by your engineering problems!

The Investment Casting process offers unlimited freedom for the thousands of designs now on the aeronautical horizon. Intricate shapes, unusual contours, metals too difficult to form or machine need not be your problem.

ARWOOD has been serving aviation with quality investment castings for over a decade . . . maintaining its leadership by meeting design specifications, quality standards, delivery schedules and competitive prices.



Write today for your copy of "A Critical Survey of Investment Casting", written especially for design, production engineers.

CASE IN POINT!

FREEDOM OF DESIGN

This magnesium rudder component on a jet bomber consists of two hollow rectangular chambers joined by a tube. A wall thickness of 0.08" is uniformly maintained, proving that extensive areas of thin section and complex curvature can be investment cast without resort to joining.

FREEDOM OF ALLOY SELECTION

In order to increase the strength and creep resistance of this jet engine strut, the material specification was changed from stainless steel to a special low alloy steel. Investment casting offers this freedom in choice of alloy at little or no extra cost.

by the withdrawal of an order eliminating overtime work at Redstone and ABMA.

Many personnel at Redstone feel that former Defense Secretary Wilson never chose to submit repeated requests for additional funds for *Jupiter* and *Vanguard* R&D to the White House. This is why President Eisenhower could publicly state that the missile agencies "got all the money they asked for," because, insofar as the White House knew, all fund requests had been granted.

200-Mile Limit Dead For Army

HUNTSVILLE, Ala.—Former Defense Secretary Wilson's controversial memo of last November 26th, which limited the Army to operational control of missiles with ranges of 200 miles and less, is expected to die an unmourned death before its first anniversary.

Informed sources at Redstone Arsenal and Army Ballistic Missile Agency here are unanimous in their belief that the Wilson memo was made obsolete by the launching of *Sputnik*. One top Army officer declared that even without *Sputnik* it would have lapsed, because of the repeated failures of both Air Force and Navy missiles in the over-200-mile range. He believes the limitation would have been scrapped in actual practice. Tests showed it to be illogical and unworkable because it imposed an arbitrary restriction on weapons whose precise range cannot always be estimated when they are in the research and development stage. It would have proved to be a needless obstacle to the detailed scientific inquiry indispensable to missile and rocket development.

Another informant here said the Wilson memo might never have been issued if the former Secretary had been allowed to retire, as he reportedly wished to do, on last January 1.

"Curley" and Koelle Confuse Missilemen

HUNTSVILLE, Ala.—As if there weren't already enough confusion in missile circles, people at Army Ballistic Missile Agency who telephone Dr. H. H. Koelle, chief of preliminary design, often wind up getting Dr. Wernher von Braun.

The reason lies in a nickname acquired by von Braun and the correct German pronunciation of Koelle's name. Von Braun is known to intimates as "Curley" because of his shock of blond hair. Koelle, in proper German, comes out "Curley" also.

"top hat design"

for Air-borne Power Supplies and Other Military and Industrial Applications

These Hoffman Silicon Medium Power Rectifiers are available in the following RETMA types: IN536, IN537, IN538, IN539, IN540, IN1095. Current ratings up to 250ma at 150°C ambient; peak reverse working voltage up to 500. Diffused junction offers long life and high efficiency.

Missile Arming Solenoid tested at 115,000 ft.

A new arming solenoid, qualified to MIL specifications has been tested at altitudes to 115,000 ft. Designed specifically for arming of a missile on a very high performance fighter, the solenoid can be adapted to other applications. The compact unit weighs only 11 oz., has a normal power drain of 0.7 amps and operates at down to 18 volts. At −65° F and 29 vdc power drain is only 1 amp. Operating temperature range is +250° to −65° F.

While specifications required testing to a lesser altitude, the solenoid was tested at 100,000′ and 115,000′. At 100,000′ altitude 700 RMS 60 cycle current was applied between winding and case for more than a minute. There was no corona discharge, arcing or shorting. At 115,000 feet the test was repeated with voltage being increased at a rate of 25 volts/second. At 825 volts a corona appeared suddenly. Apparently based on electron emission there was no sharply defined path of high conductance. Subsequent retesting of the identical unit showed no damage resulted from the 115,000′ test.

For further information on this high altitude solenoid write to:

Sputnik Sparks Reaction at Redstone

SYMPTOMATIC of the mental chaos into which the Russian *Sputnik* plunged the Pentagon, two top U.S. missile experts recently were sharply criticized in official circles for their remarks at the Barcelona sessions of the International Astronautical Federation Congress in October. Redstone Arsenal's commander and deputy commander, Maj. Gen. H. N. Toftoy and Brig. Gen. J. A. Barclay, stated in prepared speeches that the U.S. could have had a successful satellite two years ago. Reaction from Washington was quick and acid. They were, in essence, told to shut up and sit down. The rub: the Pentagon itself had approved both talks prior to the *Sputnik*. But *Sputnik* led newsmen to draw inferences that the Pentagon had not anticipated.

THIOKOL Chemical Corp.'s Redstone Arsenal contract for solid propellants for the *Hawk* short-range missile was reportedly cancelled in late October because of a failure of the solid propellant fuel to bond properly with the metal shell of the firing chamber. Prime contractor for this project was Raytheon. The job was said to have been transferred to Aerojet-General's West Coast branch. Redstone comment questioned whether this was part of an interservice political maneuver to whittle away at the Army's huge missile center in Huntsville, Ala.

"THE THING" is what Redstone Arsenal missileers call the four-stage rocket to be launched in Project *Farside* from a balloon above Eniwetok Atoll in the Pacific within a few weeks in hopes of gaining an altitude of 4000 miles. The assembly is a four-stage rocket. The first two stages consist of five *Recruit* solid-propellant Thiokol engines. Four are in the first stage. Overall length of *The Thing* is 23 feet, weight 1900 pounds. The balloon that is expected to hoist it to 100,000 feet was produced by General Mills Corp.

NO REQUEST from the Navy has been received at Redstone Arsenal for help on the controversial *Vanguard* satellite project, despite repeated assertions by Army officials that the "hardware is available." However, it is learned that a *Polaris* engine is being worked on at Thiokol's plant here, indicating that Navy and Army are at least still talking to each other.

EMPLOYMENT at Redstone Arsenal, Army Ballistic Missile Agency and Ordnance Guided Missile School, all at Huntsville, Ala., now stands at 17,500, including persons working on a $24-million building program. This is up several thousand from last year. Payrolls amounted to $81 million as compared with the county's $60-billion gross income, putting the military in the forefront in this old Alabama area for the first time.

Missile Experts Differ On Crash Progran

HUNTSVILLE, Ala.—Military and civilian experts on rockets and missiles at Redstone Arsenal and Army Ballistic Missile Agency here are sharply divided over a proposed super agency to control research, development and production of missile weapons systems.

The division of opinion follows the kind of clothing worn by the opiner: the military want a crash program; the civilians do not.

This difference is explained by impartial observers on the following basis: The military men are deeply conscious of immediate needs in the event of a sudden war and know the nation is ill-prepared in missile counterweapons. But the civilian scientists believe that potential enemies who might use missiles are actually in about the same state as the United States, in that they may have certain successful prototypes but are still far from full production of IRBM and ICBM weapons.

Another factor is the realization by members of the famous Wernher von Braun team here that one of their number would have little chance of being placed at the head of a superagency with a crash program mission. They are, after all, recently naturalized citizens and have many close relatives in both East and West Germany. They believe their best chance to achieve what they know to be possible in missile research and development would be to work under close and intimate supervision with a board of military and civilian experts who could arrive at well-considered evaluations of specific missile developments.

Kellogg Co. Alumni to Hold Reunion Dinner

Former personnel of the M. W. Kellogg Co. are planning to hold a reunion dinner during the week of the American Rocket Society Convention in New York this December. The dinner's organizers plan to hold it the evening of December 6, at Dido's Restaurant in Bayonne, New Jersey at 7:30 p.m. Reservations may be made with the restaurant at $3.75 per person.

Rigidity! At equal weight, magnesium is 18 times stiffer than steel

Magnesium's unique combination of strength and light weight gives it some outstanding abilities as a structural metal. Take rigidity, for example. A magnesium bar has 22% the stiffness of a steel bar of the same dimensions.

But stiffness increases as the cube of section thickness. So, if thickness of the magnesium is increased to twice that of the steel, the magnesium bar will be over 70% more rigid—yet weigh only half as much. And if thickness is further increased until the bars are of equal weight, the magnesium bar will be 1878%—or over 18 times—more rigid!

Similarly, a magnesium bar of equal rigidity to an aluminum bar will weigh only 75% as much as the aluminum bar. At equal weight, the magnesium bar will be over twice as stiff.

From these facts it's easy to see that magnesium can do a structural job equal to or better than steel and aluminum—and with appreciable savings in weight—whenever it's practical to increase section thickness. For more information contact the nearest Dow sales office or write to us. THE DOW CHEMICAL COMPANY, Midland, Michigan, Magnesium Department, MA 1402G-1.

LOX Plant Developed for Army Front

The Army Corps of Engineers and Air Products, Inc. have developed a million-dollar battlefront plant on wheels for the production of liquid oxygen from common air in sufficient quantity to help power *Redstone* and other missiles. The first of the plants was displayed by the Army at Fort Myer, Va., in late October.

The plant is mounted on four semitrailers and is designed to produce about 20 tons, or about 80 barrels, per 24-hour day of 99.5 per cent pure liquid oxygen when operated at normal atmospheric pressure in air of 50 per cent relative humidity. It will operate in outdoor temperatures ranging from 125°F to −25°F. The plant uses about 920 pounds of diesel fuel per hour and yields about two pounds of liquid oxygen for each pound of diesel fuel.

Two of the trailer units are identical. Each carries a 1200-horsepower diesel engine, and a rotary-type compressor which compresses air to 100-pounds per square inch. There is also an extended-surface heat-exchanger arrangement for cooling the engine and compressor and for a preliminary cooling of the compressed air as it leaves the unit. Each trailer measures 8 by 30 feet, is a little over 11 feet high and weighs about 50,000 pounds.

RMI Rides Out Govt. Economy Wave

Reaction Motors, Inc. has undertaken a program to adjust the company's costs in light of the contract reductions and stretch-outs resulting from the government economy drive. The most immediate effect of the program was a reduction in the firm's work force, but company officials emphasized that no heavy layoff was contemplated at this time.

Even though no actual cancellations of RMI contracts have been received, the company said "certain adjustments are necessary if the company is to maintain its competitive position in the industry."

National-El Ray Co. Forms From Three Companies

A new electronic and electrical component manufacturing firm has been formed by three companies in North Hollywood, Calif. Known as the National-El Ray Co., the new firm is composed of El Ray Motor Co., Valco Engineering Co., and National Electronics Corp.

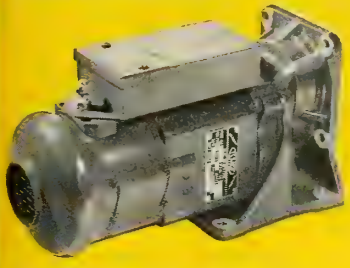
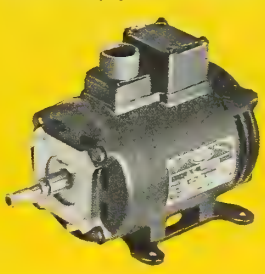
Because in missiles and jet aircraft everything has to work the first time

EEMCO AC and DC Motors

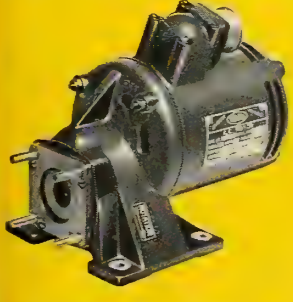
have been chosen for use in the majority of our latest aerial weapons.



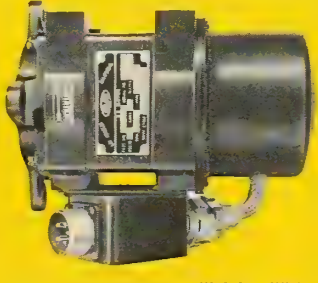
Type: C-1874 400 cycle 3 phase AC Motor and Clutch. **Weight:** 4.5 lbs. **Voltage:** 200 volts. **Output:** 650 watts. **Intermittent duty:** 12,000 rpm. **Meets Military Specification** MIL-M-7969A (ASG).



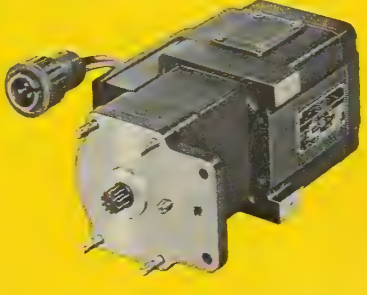
Type: D-638 400 cycle AC Motor. **Weight:** 17.5 lbs. **Voltage:** 200 AC, 20 amps at 6.5 hp. **Duty cycle:** 3.0 seconds at 6.5 hp, 15.0 seconds at 1.5 hp. **Maximum capacity:** 6.5 hp. **Continuous rating:** 5 hp at 2300 rpm, 15.8 amps, 200 volts. **Meets Military Spec.** MIL-M-7969A (ASG).



Over the years the precision, ruggedness and reliability of EEMCO products has been proven time and time again. The consistent, exceptional performance of these low-weight, high-output motors, a few of which are illustrated, has earned EEMCO industry-wide recognition. In this highly specialized field, where perfection is imperative, the widespread use of EEMCO motors and of EEMCO's equally reliable actuators is eloquent testimony.



Type: D-751 DC Motor. **Weight:** 20 lbs. **Duty Cycle:** 5.2 hp at 2100 rpm (intermittent) on 26 volts DC; 3.5 hp at 2200 rpm (continuous) on 26 volts DC. **Meets Military Specification** MIL-M-8609.



Type: D-800 400 cycle 3 phase AC Motor. **Weight:** 8.75 lbs. **Voltage:** 208 volts. **Horsepower:** 2.5 hp. **Continuous Duty:** 11,300 rpm; Equipped with thermal protector. **Meets Military Specification** MIL-M-7969A (ASG).

Type: D-899 400 cycle 3 phase AC Motor. **Weight:** 11.25 lbs. **Volts:** 200 volts. **Load:** 2.75 hp continuous output. **RPM:** 3140 rpm output at gear box. **Power factor:** 83%. **Overall efficiency:** 76% for entire unit. **Meets Military Specification** MIL-M-7969A (ASG).

Type: D-932 DC Motor. **Weight:** With radio noise filter—13 lbs., without same—12.4 lbs. **Terminal voltage:** 27.5 DC plus or minus 1.5 volts. **Load:** From .5 hp minimum to 2.6 hp maximum. **Speed:** Continuous at 12,000 rpm, plus or minus .005%. **Speed Control:** By frequency regulator supplying control field. **Meets Military Specification** MIL-M-8609 (ASG).

Type: D-927 DC Motor. **Weight:** 7.25 lbs. with 2-circuit noise filter for ungrounded systems. **Weight of filter:** 1 lb. **Terminal voltage:** 27 volts, 18 amps. **Load:** 0.5 hp. **Speed:** Continuous at 9900 rpm. Meets **Military Specification** MIL-8609.

Scientists Study Spaceship Communication

Studies that might well pave the way for communication with manned spaceships of the future or for the remote guidance of unmanned spaceships is being conducted by Lockheed missile systems division scientists. More than 50 scientists, engineers, and electronic experts will explore the problems of sending and receiving space messages and identifying objects far from earth in a large, new space-communications laboratory.

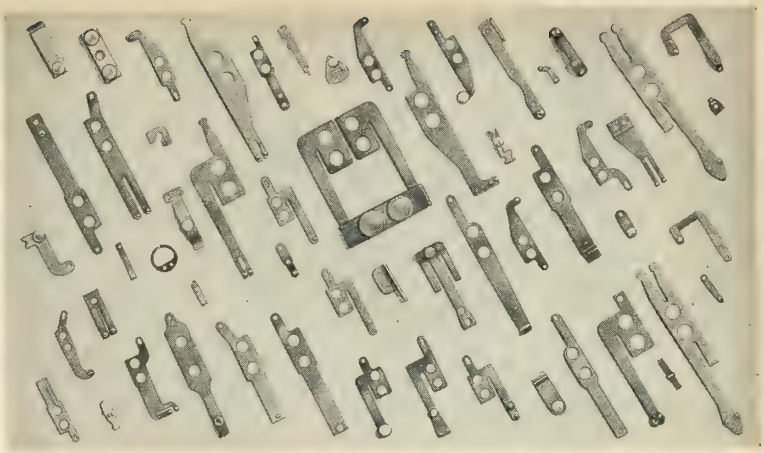
Emanual A. Blasi, head of the missile division's antenna and propagation department and in charge of the laboratory operation, said areas to be covered include:

The effect of outer space cosmic rays on radar and radio signals.

The radar pattern presented by various space vehicle and missile shapes.

The effect of the ionosphere—the electrically charged space beyond the earth's atmosphere—on such signals.

The characteristics of various antennas when installed in missiles.



The three-story, 10,000-square-foot laboratory, Blasi said, can recreate space conditions as they exist many hundreds of miles above the earth. An anechoic chamber or "quiet room," measuring 20 by 70 feet, produces electronic conditions to be found 300 miles in space by eliminating all stray electronic signals.

Much of the advance research under way is in connection with the Navy's *Polaris* ballistic missile, on which Lockheed is the missile system manager.

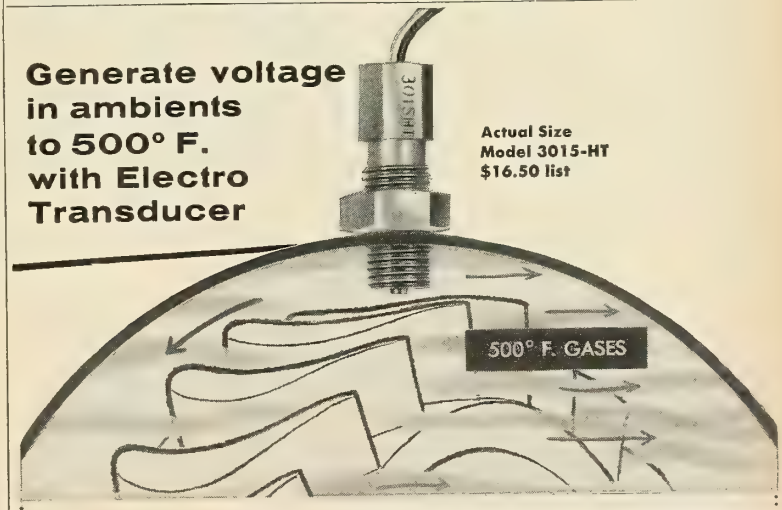
An important part of the investigations covers antenna design and installation. Whether on a missile or spaceship, an antenna will send messages of varying strength depending on its angle to the receiving antenna. Space communication depends on how well the antenna transmits in different positions when installed in a vehicle.

To further these critical studies, the new Lockheed facility has four instrumented antenna and reflectivity ranges with four sets of tracks extending up to 500 feet. Small antennas installed in model missiles are mounted on nonreflecting pylons. Motorized carriages of the pylons, remotely handled from control rooms, carry the models to various distances along eight-foot tracks for the tests.

Because of the intense interest and research in space communications, the Lockheed facility will be made available to other scientific groups on a commercial basis.

CONTACT TRICON FOR CONTACTS

Tricon furnishes contact assemblies to the electro-mechanical industry and specializes in missile control applications. At Tricon you have a team of specialists in the manufacture of switch and relay spring-blade components, as well as precious metal contacts and assemblies.



The FINE PARTS WELDING AND BRAZING DEPARTMENT at Tricon is available to semiconductor manufacturers for the precision assembly of diodes and transistors. Make a good connection and contact Tricon for contacts.

LEACH

SOLVES RELAY ENVIRONMENTAL PROBLEMS

Unique Balanced-Armature Relays meet all requirements of the most exacting operating environments — shock, acceleration, vibration and high temperatures.

In the Leach Balanced-Armature Relay, shock and vibration forces cannot move the relay armature. This eliminates faulty operation of contacts during extreme vibration and acceleration.

These Leach Relays meet or exceed requirements of MIL-R-5757, MIL-R-6106, MIL-E-5272. Typical ratings include: vibration, 20 G's to 500 cps (higher ratings available); shock and acceleration, more than 50 G's; temperature, −50° to +125°C; life, 50,000 continuous operations minimum at rated load; available 28 vac, 115 vac, 400 cps operation. At right is Leach 9226, 1.49x1.49x 1.68 inches.

Leach has gained a unique reputation for creating reliable relays, *custom-tailored* to solve specific circuitry problems. Write for your copy of the Leach Balanced-Armature Relay Catalog.

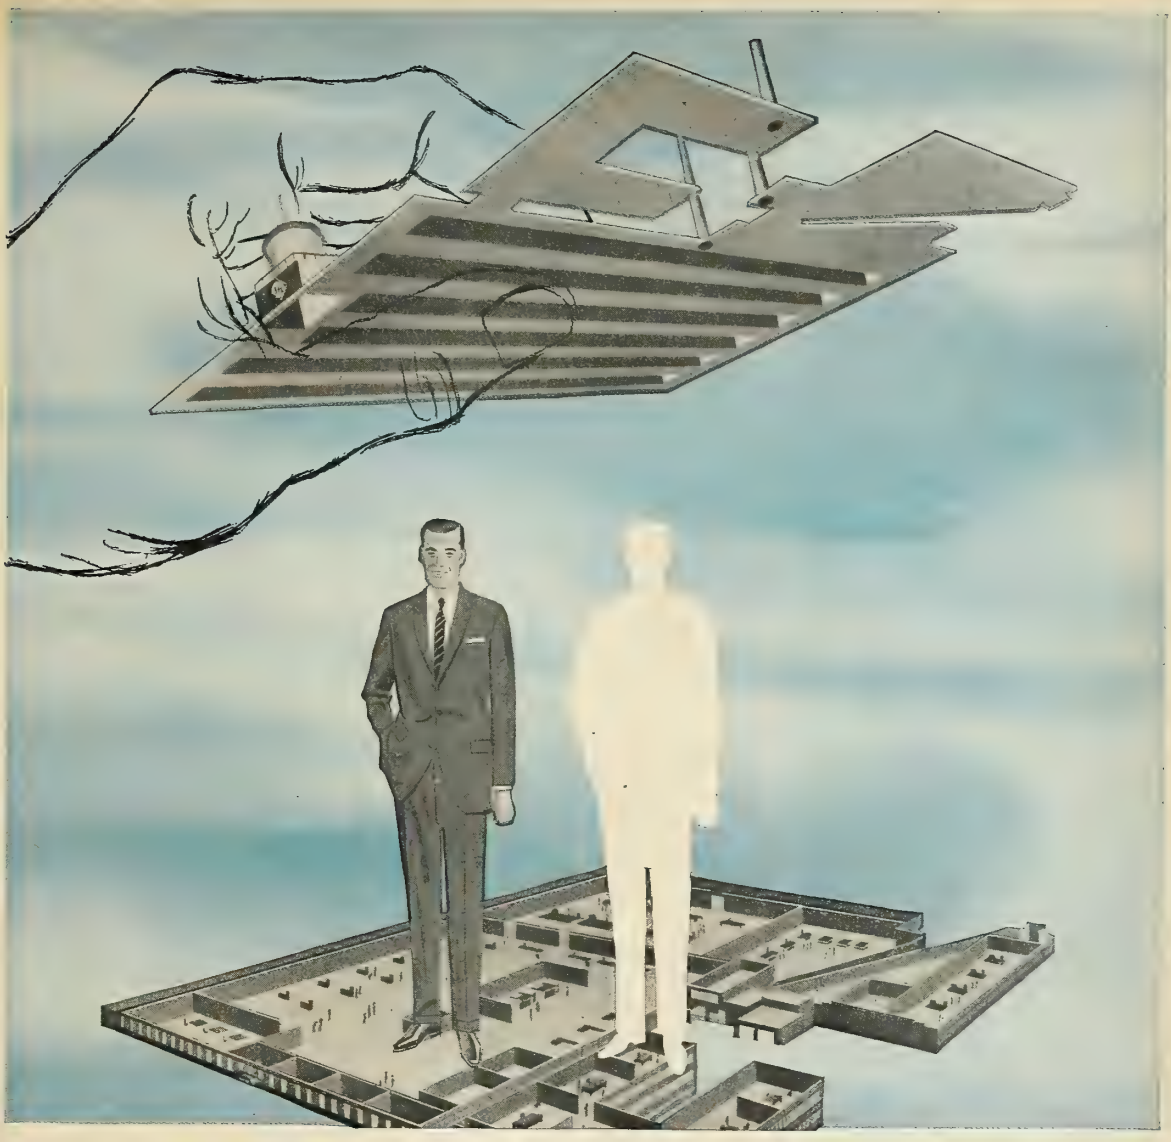
Narmco Facilities Increased by 20%

Narmco Mfg. Co.'s completion of plant No. 2 in La Mesa, Calif., adds 20% to the firm's manufacturing capacity. The one-story concrete block building houses expanded tooling, assembly, inspection and shipping facilities for the production of glass fiber laminates and sandwich-type structural components for aircraft and missiles. Narmco's backlog of orders of components and assemblies has increased 200% in the past 18 months.



R & D Program Begun By Synthetic Lithium

A joint program of research and development involving the Lithium Corp. of America and the Synthetic Mica Corp. has begun for the study of a new electronic tool—synthetic lithium flour-phlogopite mica. The new product is reportedly far superior to its potassium counterpart currently produced by Synthetic Mica Corp. Lithium Corp. will produce the lithium compounds necessary for production.

Lear Supplies *Bomarc* Guidance Parts

Lear, Inc., is producing airborne electronic intelligence components that control and direct the *Bomarc* interceptor missile to its target.

Although the Air Force does not identify specific components, Lear is known to be a producer of master references, stable platforms, computers, data links, and gyroscopic devices for automatic flight stabilization of guided missiles.

We give you a partner, when your project's under this roof

When you invite us to develop and produce aircraft systems or equipment, we immediately assign a top man to get you what you want and need.

He goes direct . . . pares away time . . . deals in a straight line with our engineers, production personnel and any others who can contribute to the success of your project.

Suppose, for example, a change in aircraft specs comes in, after production's under way. It calls for a new systems design. Your "partner" (Project Manager) acts immediately. Stops production. Implements engineering changes. Unravels any knotty problems up and down the line. So in minimum time, the *new* design is up to top-speed production.

Our Project Managers are one more reason why *under one roof* Jack & Heintz produces the widest range of aircraft electric systems and equipment available from any single source.

We invite your inquiry. Write Jack & Heintz, Inc., 17637 Broadway, Cleveland 1, Ohio.

New Liquid Rocket Engine Design Shown

An integral, self-contained liquid propellant rocket engine package was shown publicly for the first time today by Reaction Motors, Inc. The powerplant as delivered includes the entire engine system, complete from propellants to thrust chamber. It is designed to be delivered ready to be fired upon installation in the airframe.

All propellant loading is done before the unit leaves the factory so that no propellant handling is required in the field. According to RMI spokesmen, the unit can be stored in a remote location for years, and installed at the time the airframe is to be launched. Its reliability is said to be extremely high.

RMI has plans for developing the unit in a wide range of sizes and performance specifications for use in most of our current and forthcoming missiles. Flexibility in operational characteristics—choice of propellants, duration of firing, thrust level—is one of the unit's main features.

GE Fuzing Army Missiles

The Army has disclosed that General Electric is working on multi-million-dollar projects to develop warhead arming and fuzing systems for five Army missiles.

GE's missile and ordnance systems department in Philadelphia is working on or has recently completed arming and fuzing system projects for the Army's *Honest John, Little John, Corporal* and *Lacrosse* surface-to-surface missiles and on the Army's *Nike-Hercules* surface-to-air missile.

It was previously known that GE had received Army contracts for guided missile arming and fuzing development, but the full extent of the work was not disclosed until recently.

New Monopropellant Licensed to Thompson

A new heterogeneous liquid monopropellant developed by Atlantic Research Corp. has been licensed to Thompson Products, Inc. The exclusive right to purchase, use, and sell the new propellant, called Arcogel, was conveyed to Thompson by a licensing agreement. The agreement includes a royalty to Atlantic Research on future sales of the gel propellant and burner systems. Thompson Products has also given a $30,000 contract to Atlantic Research to continue development of the propellant and associated burner systems.

Use of the new substance in both gas-generating and propulsive applications is being contemplated by Thompson. Refinement of manufacturing techniques, new formulations of the gel propellant for specific applications, and development of burning systems will concern Atlantic Research scientists, engineers and technicians.

Anti-Missile Office Opens at Redstone

HUNTSVILLE, Ala.—A new facet of missile activity will begin here shortly with the opening of the Redstone Anti-missile Missile Systems Office, marking the beginning of a concentrated effort to develop the so-called "ultimate weapon" to counter ICBMs.

The new office, already condensed to RAMMSO in official terminology, will be set up with a cadre of experienced scientists and technicians from Redstone Arsenal and Army Ballistic Missile Agency and is expected to be functioning by mid-November.

One of its first projects is reported to be a faster, more accurate version of the *Nike-Zeus* missile. This is regarded as a logical first step toward development of a program to offset Russia's presumed capacity to begin ICBM production within the near future.

Establishment of the RAMMSO office was hailed here as an indication that the work of Dr. Wernher von Braun and his Army missile team has gained recognition in the wake of the accelerated missile research and development programs authorized by the new Secretary of Defense, Neil H. McElroy.

No formal announcement of the RAMMSO office has been made here but informed sources said financial support has been guaranteed and a table or organization authorized.

The basic mission of the new office will be to coordinate all military and industrial activity required for the production of the anti-missile missile.

Technique Associates Move to New Quarters

Technique Associates, Inc., manufacturers of temperature measuring and indicating instruments, has moved its general offices and plant to larger quarters at 1413 N. Cornell Avenue, Indianapolis, Ind. Mailing address of the company is P.O. Box 91, Indianapolis, Ind.

Washington Trends

By Erik Bergaust

DEFENSE SPENDING WILL RISE SHARPLY IN THE NEAR FUTURE, with most emphasis on R&D phases of missiles. With almost all research fund cuts of recent months being restored after *Sputnik* I, the Capitol Hill fur will really fly soon after November 7, if the Soviet attempt at launching something spectacular is a success. The Reds are certain to try to mark their 40th anniversary "in a most fitting manner," as the pre-*Sputnik* statement said. If, as we believe, the Reds will try for a grandstand play on that date, they could not have better cooperation from the moon. It will be a full moon—with a full eclipse. With perfect timing and guidance, a flash bomb on the moon at this time would have a hundred times more effect than *Sputnik* I. And even though this is not considered likely, who (after *Sputnik* I) will stand up and say the Reds can't do it? The Naval Observatory here says the eclipse will be visible in the western half of North America and across the Pacific to Asia. An excellent audience.

DEFENSE CUTS HAVE LEFT THEIR MARK. Due to the slashing of defense expenditures, the top-secret Lincoln Laboratories in Lexington, Mass., has been forced to announce the dismissal, as of February 1, of 160 of its personnel, many of them scientists and engineers. The breaking up of such a team is much more damaging than the layoff of a much larger number of production workers.

EDUCATION MUST BE RECOGNIZED AS THE PRIME ASSET OF THIS COUNTRY. The President's Committee on Scientists and Engineers here has been told that the 14-year-old boys of today will be the designers of our rockets and satellites in just ten short years. Nevertheless, there is not a school in the country offering a curriculum in rocket design. The American Rocket Society accepts student members only when they are 17 years old. By this time, a boy is practically an engineering student and has not had the benefit of pre-college counsel in the rocketry field.

CODE NAME FOR ARMY'S SATELLITE IS "DEAL." IT HAS PENTAGON GO-AHEAD. The program will be taken in steps. *Jupiter-C* can orbit 18 lbs. It's based on *Redstone* first stage. By replacing *Redstone* with *Thor/Jupiter* first stage and using *Sergeants* as second stage, it could conceivably place 1000 lbs. in an orbit within a few months. This program is in sharp contrast to an earlier Wilson order that Army would not work on satellites nor admit that Army interest in satellites existed. At one point, Assistant Defense Secretary McNeil dispached auditing teams to ABMA to ascertain that Army was obeying the order. This was BEFORE *Sputnik* I.

TESTS OF THE *RASCAL* WERE FROM MAXIMUM RANGE OF 100 MILES. Bell Aircraft confirms that the missile was fired from the limit.

THE AIR FORCE HAS A NEW WIND TUNNEL that duplicates "far-hypersonic" conditions, enabling scientists to study the high pressures, velocities and temperatures encountered by a missile re-entering the atmosphere. It can also duplicate the real gas effects of high-speed missiles operating in the atmosphere.

ONE OF ATOMIC ENERGY COMMISSION'S BIGGEST HEADACHES is the disposal of "hot nuclear garbage" which has been costing John Q. Taxpayer millions of dollars. It can't be disposed of, but must be stored in expensive stainless steel tanks and transferred to new tanks as it eats its way through the old ones. Rapid advance of rocket technology may provide the answer. Within 20 years, some experts estimate, it may be cheaper to load the stuff into rocket vehicles and impact it on the sun! The idea doesn't exactly intrigue us.

GILMORE

SIX COMPONENT THRUST MEASURING SYSTEM*

Completes First Year of Missile Testing

Installed at a West Coast missile testing facility, in August, 1956, this Gilmore weight and thrust measuring system indicates and records values of missile weight, propellant weight, thrust, gimballing motor forces, and thrust mis-alignment forces. Forces are translated into values represented by terms (a) weight and thrust, (b) pitch moment, (c) yaw moment, (d) roll moment, (e) XX axis sideload, (f) YY axis sideload. The system compensates for the effect of sideload with respect to wind and with respect to interaction with moments.

Computing equipment isolates all fixed components. A portable calibration unit, calibrated by the National Bureau of Standards, is included in the installation. System accuracy is 0.1%.

*Patents Pending

Soviet Affairs

by Dr. Albert Parry

It is with sad pride that this column takes credit for a major prediction come true: In my first column last July, I cited as worthwhile the conviction of an émigré source that the Reds would fire their artificial satellite into outer space on or about Sept. 17th, to celebrate the 100th anniversary of the birth of Constantin Tsiolkovsky, a Russian rocket pioneer. I referred to the forecast as an "educated guess." The Soviets fired their moon on Oct. 4th, making the prediction only two-and-a-half weeks off its mark.

•

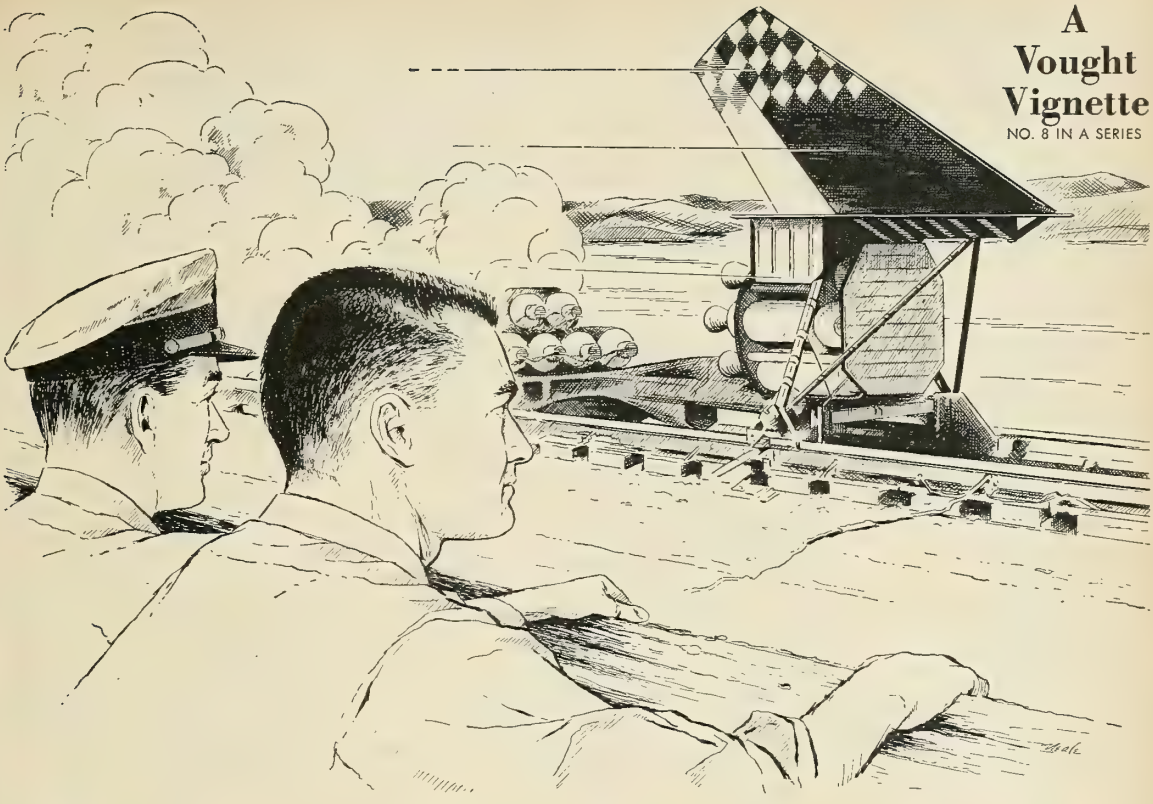
And now let me cite one more Russian prediction, this time not from émigré quarters but from a Red source, a prediction published in Leningrad nearly 30 years ago—that rockets and death rays will be used by the Soviets to defeat the United States in a future war between the two nations. This bold prophecy was made in a government publication. It was a book of science fiction, BOR'BA V EFIRE (STRUGGLE IN THE AIR), by Aleksandr Beliayev, issued in 1928 by the Communist Youth League publishing house with the approval and under the auspices of the Soviet state itself.

•

That 1928 fantasy is startling and revealing, yet it is rare in the sense that the book came out in a small edition and, to my knowledge, has not been reprinted in Russian or translated into any other tongue. Its export from the Soviet Union was not encouraged by the Kremlin. In all my diligent, protracted search I have to date succeeded in locating only two copies of this book (in its Russian original) in this country.

•

Why so scarce and obscure? The reason may be that the Soviets might have had second thoughts about the book soon after its publication. The frank story tipped the Red hand too early in the long-range timetable of America's destruction. At that time, in the latter 1920s, the Kremlin wanted American aid in Russian industrialization. It also wanted our recognition of the Soviet government. And so the daring book, although commissioned by the government, was practically "closeted" by the very same Red government.



•

Yet consider the time and the setting of that old Soviet prophecy. Three decades ago, while Red Russia was feeble and seemingly knew not which way to turn in order to survive, and while we were at the height of our Coolidge-era prosperity and power, the ruling class of the Soviet Union had this arrogant confidence that America and the rest of the West were doomed—that the "bloated capitalists" would perish through the coming Red might of rockets and rays to be delivered against New York and Washington by air, the weapons already then theorized by the little, aging provincial teacher of high school physics and mathematics, Constantin Tsiolkovsky of Kaluga, and his vigorous Soviet followers.

•

Truly no greater service toward awakening America from her complacency can be performed by some American publisher than through publishing this 1928 novel by Beliayev in English.

A Vought Vignette
NO. 8 IN A SERIES

The structures engineer who found a fast detour

"Advise and assist on structural problems. Do what you can to keep the program moving . . ." With this outline of his liaison duties, Stress Analyst Ed Clay accompanied Vought's Regulus II missile to its desert test site.

On the desert, Ed found a dearth of structural problems. Regulus II reliability gave the flight test program tremendous momentum. In quick succession the missile notched 10 flights. When time came for a critical high-speed test, the program was three months ahead of schedule!

Then, the very fact that things had moved so fast threatened to rob the program of the time it had gained.

As Vought had planned, a wind tunnel flutter test had to precede the upcoming high-speed flight. But Vought's prearranged date at a government tunnel was over a month away. The facility was booked solidly up to the appointed day. And Vought's own Mach 5 tunnel was under construction.

Then Ed revealed the scope of his liaison. It had ranged to the rocket test track at nearby Edwards Air Force Base. There, with the help of a cooperative track project engineer, Ed had spotted a rusting rocket sled, left behind from a radome test. Now, if the sled could be rigged to carry that spare Regulus fin, Ed figured, they might get flutter data before the tunnel test.

That changed Ed's state of liaison. All Vought was suddenly at *his* service. Shopmen reworked the sled to mount the fin. Instrumentation technicians fitted the fin with gages and transducers. Vought's top flutter men double-checked, raised their eyebrows, then endorsed the whole thing.

At the track, moments before the rockets exploded, Ed had a twinge of doubt. His sled was a monster, indeed. Air loads would be terrific . . .

Then the sled shot off on the first of two successful trips that revealed all the data required.

At Chance Vought, there's liaison in spirit as well as in name. It allies engineers of many specialties and viewpoints against mutual problems. It builds channels instead of walls between diverse technical areas. It's another reason why top engineers are choosing Vought — *to keep abreast of all fields while advancing in one.*

CHANCE VOUGHT AIRCRAFT

World Astronautics

By Frederick C. Durant III

A resolution to establish a Joint Committee on Earth Satellites and the Problems of Outer Space has been introduced by Rep. James G. Fulton (R-Pa.). This bill, currently referred to the Committee on Rules, has a great potential for bringing to the attention of Congress and the public the ramifications of extended satellite programs. The bill as it now reads calls for full and current briefing by the DOD on "all matters . . . relating to the fields of earth satellites and outer space." It goes on to state that, "any Government agency shall furnish any information requested by the Joint Committee with respect to such activities or responsibilities" and that, "all bills, resolutions or other matters relating primarily to the development, use or control of the earth satellites and outer space shall be referred to this Committee." Truly, this Committee would have great potential influence in the development of astronautics, particularly during the next few years.

•

Original reports attributing the origin of the delightful "Geschutenwerkes Werdebuke" (m/r September, p. 54) to ABMA have not been verified. Two key technical members of the ABMA staff were delighted to obtain copies recently. Former German nationals, they commented privately that they had not seen it before. The author is probably a native born American. He deserves credit for a charming bit of whimsy and we would like to see him identified. Incidentally, a few copies of the complete list of translations of 43 terms are available on request to this column.

•

The Associacion Argentina Interplanetaria (AIA) has expanded their rockets and satellites course. Ing. T. M. Tabanera, AIA president, has organized the course which is being held at the Sciences Faculty of the University of Buenos Aires in collaboration with the Institute of Scientific Research on Weapons. The course is in five parts: rocket motor design, energy sources, ballistics and guidance, electronics and hypersonic aerodynamics. The course runs three and one-half months.

•

Preliminary meetings toward the forming of a Korean Astronautical Society have been held during the past few months in Seoul. Byung June Chang has attracted the support of local university professors and has requested registration by the Ministry of Education.

•

Niichi Nishiwaki, professor of mechanical engineering at the University of Tokyo, has completed a year as visiting professor at MIT. While in Cambridge he conducted basic research in combustion problems. He returns to Tokyo via Europe where he will visit a number of aviation and rocket propulsion establishments. Prof. Nishiwaki is active in both the Japanese Rocket Society and the Japanese Astronautical Society.

•

At the Annual Meeting of the Deutsche Arbeitsgemeinschaft für Raketentechnik (DAFRA) last month, President A. F. Staats announced the grant by the city of Bremen of DM5,000 to the Society for their experimental work. This significant sum is in addition to contributions by numerous industrial concerns. While there I saw motion pictures of the August firings of sounding rockets at Cuxhaven. Only a tantalizing glimpse was given of two larger two-staged prototypes which have yet to be tested.

Manufacturing at Marquardt

by
Roy E. Marquardt
President

Another barrier — the PRODUCIBILITY BARRIER — is currently being penetrated by Marquardt engineers. What do we mean by PRODUCIBILITY BARRIER?

Advanced designs for supersonic ramjet powerplants coming from the drawing boards call for strength to weight ratios and high-precision tolerances previously unobtainable. New high-temperature alloys are meeting the metallurgical demands, but do not readily lend themselves to conventional machining and fabricating techniques.

Those members of the Marquardt team charged with pioneering new production methods comprise our Van Nuys Manufacturing Division. Here — under the direction of John S. Liefeld — creativeness and imagination join forces with a thorough understanding of standard shop practices to produce acceptable hardware. But management realizes that to do his best work the engineer must be supplied with the most up-to-date tools of his trade.

Exemplifying our continuing efforts to this end: a specially designed, half-million dollar roll-former is being added to the company's ever-expanding production facilities. This machine will be capable of spinning conical, tubular, venturi, and parabolic configurations of a size heretofore considered impossible or impractical to fabricate as a single piece. A completely safe, close-up view of the actual metal forming will be afforded the operator by means of two closed-circuit TV cameras mounted on the machine frame.

We are also acquiring other automatic machines — numerically controlled units capable of multiplying the output of their manually operated counterparts several times. Utilizing punched and magnetic tape, these machines are expected to greatly expand the scope of Manufacturing Engineering.

Another of the modern production techniques at Marquardt puts to use modern optics equipment for the construction of prototype engines.

At Marquardt, the engineer will find a broad range of challenging assignments and the opportunity to further his career through supplemental educational programs.

Within this Division, engineering openings exist now for:

METHODS ENGINEERS — PROCESS ENGINEERS
TOOL ENGINEERS — AUTOMATION ENGINEERS
NUMERICAL CONTROL ENGINEERS

For information about these positions and the professional engineering environment at Marquardt, we invite you to write Jim Dale, Professional Personnel, today.

A FAMILY OF FINE FASTENERS

FOR SPECIFIC APPLICATIONS IN HIGH PERFORMANCE AIRCRAFT AND MISSILES

FROM LEFT TO RIGHT

HI-LOK FASTENER — a controlled-preload fastener featuring lightweight, exceptional fatigue values and fast, silent installation; for use in all types of structure, both airframe and missile. HI-TORQUE BOLT — a countersunk bolt featuring high installation torque values, positive removal, high tensile strength and fatigue life, temperature and corrosion resistance, and a recess which is adaptable to any material. HI-SHEAR RIVET — a fastener with the strength of a bolt and the speed of installation of a rivet. BLIND BOLT — a high strength blind fastener for use in all types of structural application, both production and repair, where the work is accessible from only one side. ANCHOR BUSHING — a low cost bushing which makes possible the use of sheet metal for precision drill templates.

These fasteners are available in production quantities in a full range of sizes, head styles and materials to meet normal and high performance requirements. Hi-Shear Engineers are engaged in extensive research and development, applying new concepts to product design, to assure the structural integrity of future aircraft and missiles. Production facilities insure reliable service to the customer, and service engineers are immediately available to solve problems in the field.

MAGAZINE OF WORLD ASTRONAUTICS

an m/r analysis:

Law Must Precede Man Into Space

By Andrew G. Haley

President, International Astronautical Society

NEVER BEFORE in the history of mankind has the necessity arisen so quickly to state legal parameters in connection with a vast new area of social change. The legal problems presented by the advent of space flight have been climacteric, and technology has far outstripped the formulation of the legal rules. The gap has widened to the point that the peace of the world is threatened.

The consent of all nations to the satellite program of the International Geophysical Year and the active cooperation of most nations have resulted under familiar and accepted principles of international law in giving full legal validity to the present IGY satellite program. But this is the one and only achievement. Space law still completely awaits development.

The most unfortunate development in connection with the orderly statement of space law has been the involvement of the problem in the proceedings of the United Nations Subcommittee on Disarmament in London. This involvement was inevitable because the question of control of objects entering outer space was bound to arise. The problems of space law found their first and most critical examination in the intense political atmosphere of the London Disarmament Conference. The statement of space law problems and the formulation of jurisdictional concepts and regulatory rules should long since have been undertaken by appropriate juridical bodies of the United Nations and of the International Civil Aviation Organization.

In arriving at a level-headed statement of the jurisdiction of space law, the lawyer must turn for help to the physicist to ascertain just where "air space" ends. We must ascertain the outer boundary of air space because hundreds of local laws of more than 90 nations and restrictions of a score of international treaties are bound tightly by the physical concept of air space.

Ironically enough the lawyer finds the main crackpots and nuisances among engineers and sociologists who assume the role of amateur lawyers and give vent to rather silly if harmless rhapsodies in a field wholly unfamiliar to them. To them the real problem of delimiting air space is wholly unnecessary. The sound scientist avoids legal interpretation, while at the same time making essential contributions by staying within his technical expertise, and keeping the lawyer well-advised on appropriate physical phenomena. Such has been the most helpful role of Dr. Theodore von Karman.

Dr. von Karman has suggested practical methods of formulating the jurisdiction of air space. Last spring he delivered a paper at the University of California entitled "Aerodynamic Heating—the Temperature Barrier in Aeronautics." In that paper he had occasion to use a diagram made by Masson and Gazley of The Rand Corporation showing the possible ranges for continuous flight in the velocity-altitude coordinate systems.

Pursuant to von Karman's suggestion I devised a diagram (Fig. 1) containing curves showing the high-altitude sounding rocket regime, the earth orbital satellite regime and the Kepler regime (earth escape velocity) and some supernumerary information. But most important is what we shall now call the Karman primary jurisdiction line.

To establish sound bases for demarcation of air and space jurisdiction, it is necessary to consider that the conditions for achieving aerial flight, that is to circle at constant altitude, are that weight equals aerodynamic lift plus centrifugal force.

The aerodynamic lift decreases with altitude because of the decreasing density of the air and in order to maintain continued flight beyond zero air lift, centrifugal force must take over. Consider the flight of Captain Ivan C. Kincheloe, in which he took the X-2 rocket plane to 126,000 feet altitude. His flight was strictly an aeronautical adventure and did not partake of space flight. At the altitude indicated, aerodynamic lift carries 98 per cent of the weight and only two per cent is centrifugal force, or "Kepler force." It will be noted that in the corridor of continuous flight when an object reaches approximately 275,000 feet and is traveling at 25,000 feet per second, the Kepler force takes over and aerodynamic lift is gone. This is a critical jurisdictional boundary.

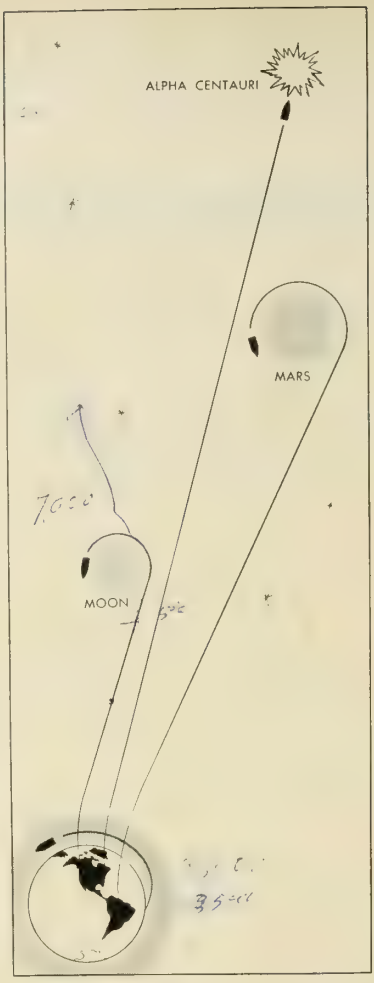
Fig. 1 is intended to be illustrative. The Karman line may eventually actually remain as shown in Fig. 1 or, after due consideration, the line may be significantly changed. In any event, this is the line at which "air space" terminates.

Any such definition should be finally promulgated through the United Nations and implemented by the In-

ternational Civil Aviation Organization (ICAO). In determining the Karman line, the United Nations and ICAO will require the advice of a committee in stating the final definitions and in drafting detailed regulations. The basic statutes of ICAO will have to be broadened by international agreement and the name undoubtedly must be changed.

The first important action taken so far was the establishment in Barcelona by the International Astronautical Federation of the Cooper Committee, headed by world-renowned Professor John Cobb Cooper. It will consist of three lawyers and four physicists who will define air space and space jurisdiction.

It would be senseless to build a surface transatlantic steamship to perform the undersea functions of a submarine. The functions of the aircraft and the rocket ship are essentially even more disparate. In arriving at a reasonable Karman line, physicists and lawyers inevitably will reach agreement as to the point where the aeronautical vehicle no longer may perform efficiently and within reasonable physical and engineering parameters. It may be useful to examine, momentarily, some of these parameters:



A. M. Mayo has pointed out that control of the pilot's immediate environment from the standpoint of pressure and composition would become increasingly difficult as a function both of the length of time of flight and of the pressure reduction and change of atmospheric composition.

He goes on to state that at altitudes below approximately 70,000 feet the problem of pressurization and composition is taken care of relatively easily by pressurizing outside air. At higher altitudes, pressurization of outside air becomes increasingly difficult both from the standpoint of the power required and from that of handling the very high temperatures resulting from extreme ratios.

Many other considerations will enter into the final determination of the Karman line. The danger of material collisions with the airframe, escape problems, the problems posed by combined stresses and multifold fundamental questions of the construction of aircraft, as such, will all enter into the final decision.

H. Strughold points out that with increasing altitudes, some of the biological effects creep in gradually, while others rise at sharply defined levels. On the whole, the road from the surface of the earth to free space displays characteristic ecological stages. These stages are determined by the functions which the atmosphere has for man and craft.

He points out that we must first consider the oxygen component in the chemical constitution of the air. In this respect, only the lower half of the troposphere can be designated as the physiological atmosphere or the ecosphere of the air. It is in this narrow zone that the stage for the drama of life on our planet is normally set. Only this layer deserves the name "atmosphere," which, from the Greek "atmos," means "breath."

The above sketch illustrates the four basic jurisdictional regimes: (1) the earth's shaded area shows the Karman primary jurisdictional line delimiting the air space; (2) the lunar orbit delimits the Keppler regime of earth; (3) the Martian orbit illustrates the solar Keppler regime which ends at a point beyond Pluto; (4) the Alpha Centauri trajectory is one illustration of the Sänger regime.

E. O. Hulbert states that the region of the atmosphere from 0 to 6.2 miles, where the temperature falls rapidly with increase of altitude, has long been called the troposphere. The region from 33,000 to 66,000 feet, where the temperature is approximately constant, is called the stratosphere.

The ionosphere has its own well-accepted nomenclature, the terms D, E, F_1 and F_2 designating the four ionized regions with maxima of ionization at about 43.5, 62.1, 124.3 and 186.4 miles respectively. Aside from these, there is no generally accepted terminology of upper atmospheric regions.

The terms upper and outer atmosphere are used with different meanings depending on the context, and it is best to keep their meanings fairly elastic. The region from about 12.4 to 21.7 miles, which embraces most of the ozone, has been called the ozone layer or ozonosphere. It has been proposed that the region from the top of the stratosphere, at about 12.4 miles, to the minimum of temperature, at about 43.5 miles, be called the mesosphere and the region of increasing temperature, somewhere above 62.1 miles, the thermosphere.

The exosphere has been used to refer to the outer fringe of the atmosphere, where the air particles execute long elliptical orbits bouncing outward from impacts with other particles and falling back under gravity. In general, Hulburt concludes, the physical properties of the various regions are not yet well enough known to permit their fixation by an accepted terminology.

In their most recent writings, Cooper and Meyer have sought to locate air space jurisdiction at a point in the ocean of air surrounding the earth where aerodynamic lift is gone. These authorities have avoided the mistakes of engineers and sociologists suddenly turned amateur lawyers, who are attempting to locate air space jurisdiction in such heterodox and altogether eclectic regions as the thermosphere, exosphere, mesosphere and ozonosphere, even the nomenclature of which is doubtful, and none of which has any reference whatsoever to the problem at hand.

Under certain conditions national jurisdiction will be *quite indirectly* but effectively maintained over what is called by Professor Cooper "contiguous space." In the near future the nations of the earth will be offered point-to-point rocket communications involving many services.

The trajectories of each of these routes will be different, and will involve different altitudes. Some of these rockets will describe a trajectory requiring heights of 300 miles or less, and others will probably require heights in excess of 1000 miles. National jurisdiction will be effectively maintained by the granting of launching and landing rights, and thus there will be indirect national control with respect to point-to-point earth rockets over contiguous space.

The international regulation of

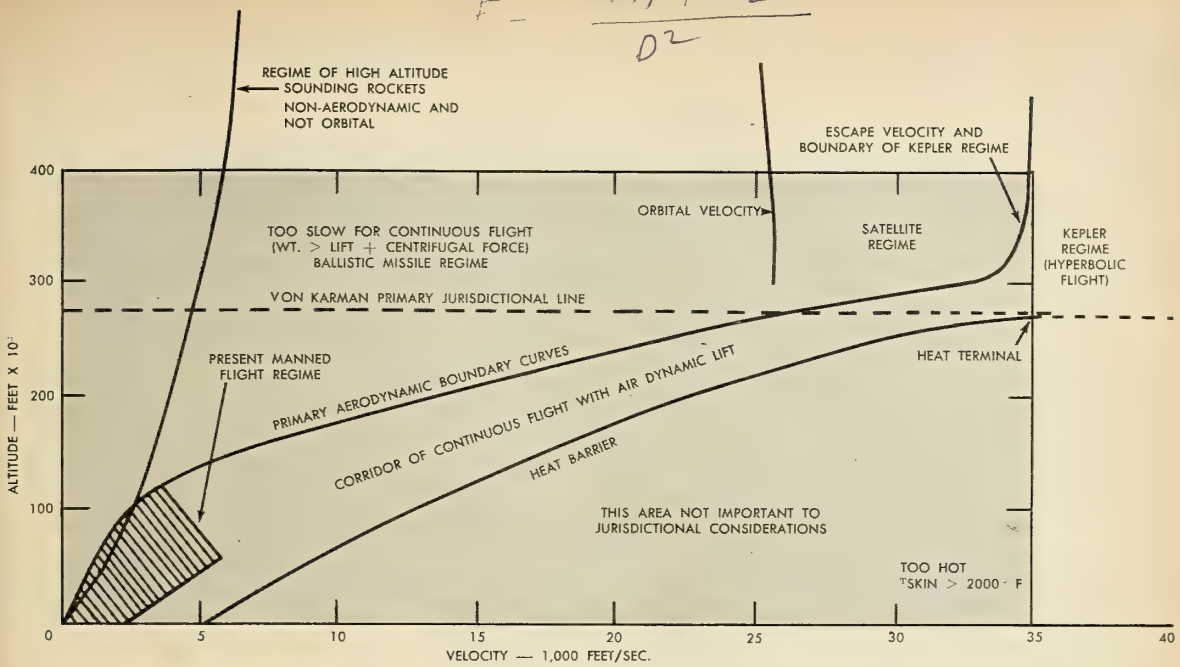


Diagram showing regimes of atmospheric and extra-atmospheric flight and depicting jurisdictional boundary lines.

point-to-point earth rocket vehicles will be under the jurisdiction of a successor international governmental organization to ICAO. The very problems of locating instrumentation along the manifold aerodynamic and nonaerodynamic routes, orbits and trajectories will require the highest degree of international cooperation and regulation for the operational efficiency and safety of all concerned.

The aircraft, the point-to-point earth rocket ship, and the spaceship capable of freely maneuvering in outer space when navigating around earth or landing on earth, will each need navigation aids, anticollision devices, secondary radar, communications systems, meteorological services and many other international aids and services. In every instance of movement to or from any point on earth, the national licenses and permits which are the essential prerequisites of national society will be needed.

Mankind must mature appreciably to create an international authority having sole and complete jurisdiction over space flight and such an achievement must wait the wise action of future generations.

No single nation has a paramount claim to outer space nor a monopoly on the scientific genius which will soon make its exploration and exploitation a reality. The field of astronautics will progress only as international cooperation in the field is achieved.

National sovereignty ends for all purposes with the Karman line. By way of analogy, the Stephen Decatur Doctrine demonstrated 150 years ago, that:

> The seas beyond reasonable coastal areas [space beyond the Karman line] are free and subject to control by no single despot or nation, and
>
> The sponsors of ships at sea [spaceships in space] must be responsible for the conduct of their vessels.

More than 50 nations are participating in the IGY. This involves very extensive utilization of governmental and nongovernmental facilities and personnel. Active participation in the program is required of each nation, of its army, navy, air force and coast guard personnel and facilities; of such governmental agencies as those concerned with standards, radar, radio, meteorology, weather, coast and geodetic surveys, geological surveys, and all types of official scientific and research organizations.

In addition, parallel, nonofficial institutions are involved, including universities and observatories in those few countries where such institutions are not controlled by the state. By agreeing to support actively the satellite program, the foregoing nations also agreed to the legal validity of the project.

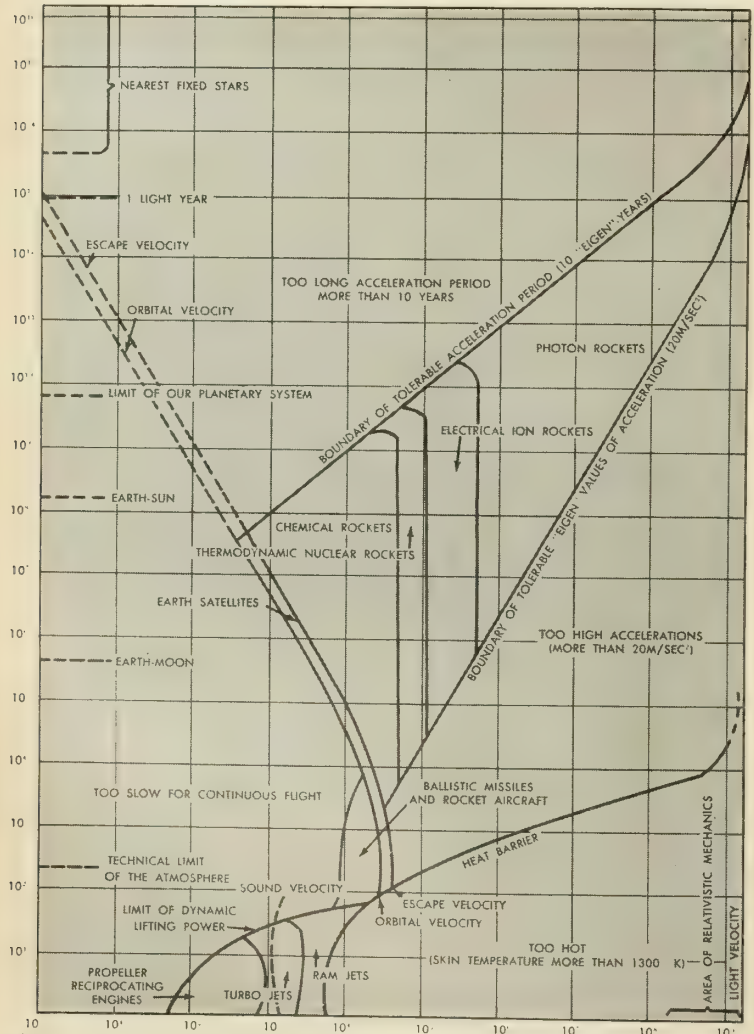
On the basis of sound principles of international law, the nations of the world may not protest the flight of a nonmilitary artificial satellite over their territories when the purpose of such flight is the accumulation and dissemination of scientific data which shall be made available without restriction to all the nations of the world.

No single formal treaty emerged from the myriad agreements involved in the IGY. Nevertheless, a valid and binding world pact emerged from these acts of agreement and cooperation.

The international pact, in written form, may be abstracted from the thousands of documents and exchanges from which the living IGY has evolved. There is nothing about a single formal treaty which makes it sacrosanct or makes it even an essential source of international law.

In many instances the principles set forth in the treaty itself may have been established in international law long prior to the signing of the formal document itself. A rule of international law does not receive its validity from its enactment into a legal instrument, such as does an international law, which is valid although not enacted in such legal instruments. There are rules of international law which are not valid, although enacted in such instruments. Enactment, therefore, is no objective criterion for the alleged validity of a rule of international law.

The social scientist, just as clearly as the natural scientist, has the duty to acquire base-line data and then to implement such data in the dynamic evolution of society. The advent of the rocket motor, with its potential of unlimited access on the earth and in space, presents a great new mutation requiring the immediate and careful attention of the social and natural scientists. The base-line material of the law-



yer has always been invested in the mores of mankind from which he must extrapolate principles of justice.

At this time we may postulate necessary rules of space exploration—namely, in any instance where there is reason to believe that intelligent life exists on a planet, no earth spaceship may land without having satisfactorily ascertained that 1) the landing and contact will injure neither the explorer nor the explored; and 2) it has been invited to land by the explored.

The regulation must be adhered to without exception, or we will project into space and perpetuate the bleak and devastating geocentric crimes of mankind. Further, we must conquer certain problems of semantics before we are worthy of space travel beyond our solar system.

This principle is just as old and simple as the basic idea of justice itself. It is a kind of compact not to harm or be harmed.

Metalaw was earlier defined as the law governing the rights of intelligent beings of different natures and existing in an indefinite number of different frameworks of natural law. An intelligent multidimensional creature would probably be so inferior as to require most considerate and sympathetic understanding and treatment by three-dimensional creatures existing in a three-dimensional universe, such as we conceive of mankind. The intelligent mankind concept runs into deep trouble *vis a vis* an intelligent two-dimensional creature existing in a three-dimensional continuum, and problems of metalaw become truly complicated when one considers a man's relationship with intelligent two- and one-dimensional creatures existing in a two- or one-dimentional universe.

The Eugen Sänger schematic diagram illustrating all possible flight regimes. Verticle scale represents flight altitude in kilometers vs. earth velocity in km/hr (horizontal).

With the assistance of Dr. Eugen Sänger and Dr. Irene Sänger-Bredt, the possible types of flight regimes, including those regimes which might philosophically spell the elimination of a dimension, were illustrated by a diagram (Fig. 2). Within this coordinate system are plotted the domains of aeronautics, the transition domain from aeronautics to astronautics and the domain of astronautics.

Proper aeronautics, characterized by air-breathing propulsion systems, reaches up to about 50 miles. It lies between the two well-known limiting curves—namely, the limit of aerodynamics lifting power and the heat barrier. This domain plot shows an onion-peel shape (attaching one onion peel to the next by increasing flight velocities and altitudes) when progressing from propeller reciprocating engines to turbojets and then to ramjets.

Though aerodynamic lifting power is gradually replaced by the centrifugal force from the trajectory curvature beyond a velocity of 62,000 miles per hour, the intersection of the curves of limit of aerodynamic lifting power and heat barrier is nevertheless physically real and constitutes as the utmost limit of the ramjet also the definite limit of aeronautics.

Contrary to this, ballistic rockets and rocket aircraft are not limited by the limit of aerodynamic lifting power due to their "non-airbreathing" propulsion systems and they can fully exploit the lifting support of the inertial forces due to the trajectory curvature from about 3730 miles per hour on, so that their possible altitudes of flight increased to several thousand miles and their flight velocities approach orbital velocity. The aerodynamic lifting power then is completely replaced by the inertial forces of the circular orbit about the earth.

These ballistic missiles and rocket aircraft form the transition domain from aeronautics to astronautics, which flows into the domain of pure astronautics with the reaching of the orbital velocity. Hence, only a small corridor connects aeronautics with astronautics.

Within the narrow band between orbital velocity and the constant $\sqrt{2}$-times larger escape velocity lie the artificial satellites on the earth. This band curves to decreasing flight velocities with increasing altitude due to the decrease of the gravitational acceleration by the square of the altitude over the earth.

Beyond this band there opens the immense vistas of interplanetary, interstellar and intergalactic space flight, in a structural shape surprisingly similar to that of aeronautics according to present concepts. ★

Manned Rocket Aircraft

By Frederick I. Ordway III

THE HISTORY of the rocket airplane can be compressed within a 30 year span, which, offhand, seems a rather considerable period for this almost novel device. Today, we are interested in the rocket airplane for two major reasons. First, the enormous power made available in a relatively small package allows very high velocities to be built up over short periods of time. Second, the rocket airplane offers an important research potential.

There is no particular difficulty in discussing the history and developments of the pure rocket airplane: it either does or does not have solely a rocket powerplant.

Little attention will be given to pure JATO applications of rocket power. A B-47 or an F-84 are completely operational without considering the fact that they may employ rocket-assisted take-off techniques. On the other hand, the XF-91 was as much built around its rocket engine as it was around its turbojet.

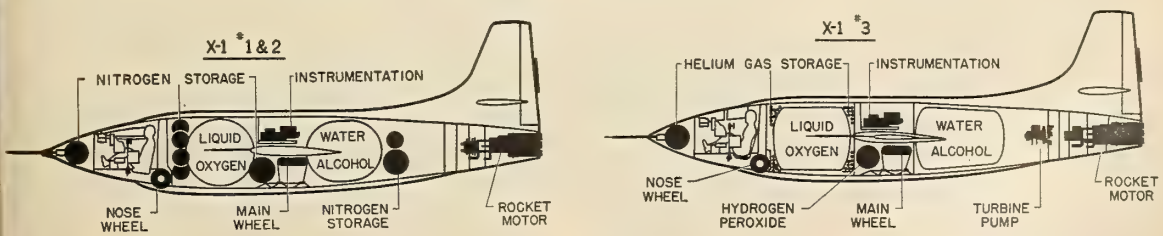
The world's first rocket airplane flight took place in Germany. Germany, too, put the first operational rocket fighter into the skies during World War II. Since then, the United States, France, Great Britain and Russia have made varying efforts in this pioneering field, and it seems that, in one form or another, rocket airplanes are with us permanently. The first manned spaceships may well be extrapolations of today's rocket-powered research aircraft.

For a brief rundown, Germany and Japan are largely identified with wartime efforts; the United States has led the world since then; France is assuredly Western Europe's greatest rocket plane promoter; Great Britain is moving ahead rapidly; and Russia represents somewhat of an unknown.

German Developments

Germany developed the first rocket plane in the 1920s. M. Valier conceived of a project wherein solid rockets would power a small airplane with an auxiliary piston engine for emergency.

On July 11, 1928, at Wasserkuppe, F. Stamer attempted a flight with a rocket-powered glider made available by the Rhon-Rossitten group. Slow-burning Sander's 25- and 30-pound-thrust solid rockets used initially failed to get the plane off the ground. On a third attempt, with two 40-pound-thrust units, take-off occurred, and a 4000-foot-long run of just over a minute was recorded. Later attempts were unsuccessful.



The Opel-Sander-Hatry (pilot-rockets-builder) rocket airplane, with Fritz von Opel as pilot, succeeded in flying on Sept. 30, 1929, at Rebstock (Frankfort) after two preliminary attempts. Power was provided by 16 powder rockets. The flight was nearly a mile long, lasting over a minute. Top speed was reported to be some 70 miles per hour. There was also a tailless *Espenlaub* plane with a 300-pound-thrust engine which could get off the ground very rapidly.

Several events led directly into Germany's wartime rocket airplane developments. Work began at Hellmuth Walter Kommanditgesellschaft in Kiel around 1935 on hydrogen peroxide engines, and thrust ratings went up from 650 pounds to over 2000 pounds in 1938. Turbopump systems gradually replaced pressurized gas feed systems, and bipropellant philosophy gradually replaced the monopropellant.

The first real rocket airplane appeared toward the end of 1938. The Heinkel He-176 reached about 550 miles per hour on a 1300-pound-thrust liquid Walter engine. Walter's engines were beginning to prove themselves and it was not long before other planes, such as the Messerschmidt Me-163 *Komet* mid-wing monoplane and the Bachemwerke *Natter* ram rocket, were using them.

The Me-163 took off and landed much like the modern *Baroudour* in that it jettisoned its take-off assembly and landed on skids. A short plane, the Me-163 was 20 feet long and had a wing span of 32 feet. It weighed up to 11,000 pounds and had a normal 52 pounds per square foot wing loading, which became 14 pounds per square foot when its propellants were exhausted. It featured sharp leading-edge sweepback.

Two major engines were used on different models of the plane: a "cold" engine operating only on T-stoff, while a "hot" engine used bipropellant C-stoff and T-stoff. With the latter combination the plane could reach nearly

Drawings illustrate the internal arrangement of the X-1 series of research rockets. Basic changes are noted in gas storage.

The X-1A, a modification of the "sound-barrier buster," reached a velocity of Mach 2.5.

600 miles per hour, but could fly only about 10 minutes.

At one time during the development program the Junkers firm took over the concept for improvement recommendations and came up with the Ju-248, a somewhat slimmer design. Messerschmidt got it back, however, and the Me-263 resulted, a plane that never was tested under powered flight.

The *Natter (Viper)* was the smallest rocket airplane concept to come out of war-time Germany, and it reached the flight test stage. Four solid diglycol 109-533 boosters made by Schmidding would lift *Natter* at a rapid rate of ascent. Subsequently a Walter C/T-stoff engine would take over.

Vertically launched, the all-wood *Natter* was cheap and could be built rather quickly. From 24 to 33 electrically-fired 7.3-cm *Fohn* air-to-air rockets were carried in the nose and fired simultaneously; once the attack had been made, the pilot would parachute to ground and the motor would jettison and likewise be parachute-recovered. With under 8000-pounds thrust, it had an acceleration of 2¼ g. The top speed was just over 600 miles per hour, and its ceiling was under 10 miles.

Natter weighed about two tons and incorporated an autopilot used until final closure, when the pilot was to take over. Some 20 pilotless tests were successful, but the one piloted attempt failed.

No discussion of World War II German rocket airplanes is complete without mention of the Sänger antipodal bomber. As far back as the early 1930s Euger Sänger was testing oxygen/fuel oil rocket engines in Vienna and he designed a plane looking much like the U.S. X-1. With Irene Bredt, he developed his wartime scheme of a rocket manned bomber that could hit targets on the other side of the globe.

The bomber would have an apogee of some 160 miles (top speed: four miles per second), which meant it would be well outside the effective atmosphere. Its re-descent path would be so calculated that the plane, upon reaching denser atmospheric layers where aerodynamic forces come into play, would ricochet back into space. By following such a "skip" path its range would be enormous.

In the words of Sänger and Bredt: "The launching and climb of the rocket bomber have the purpose of giving it, with a minimum of fuel consumption, the high velocity necessary to carry it through its long glide path; they are in the nature of an impulse which lasts only for a few minutes." They assumed the bomber would be catapult-launched along a rather long track; in effect it would have been a rocket-sled boost which would provide an initial 1000 miles per hour. This great idea remained in the project stage only, though rumors persist that the Russians have, since the war, developed the concept for their own use.

Sänger and Bredt wrote during World War II the following conception of an attack on New York by an antipodal bomber:

As an example of area attack with single propulsion and full turn, we use the attack on New York at a range of 6500 km. For $c = 4000$ m/sec, the bomb load is 6 tons, and the detailed attack runs as follows: the motor starts to work 36 seconds after the take-off at 12 km. distance from the take-off point, and consumes the total fuel supply of 84 tons in the next 336 sec. At the end of the climb process, the aircraft reaches a velocity of 6370 m/sec, an altitude of 91 km., a distance of 736 km. from the point of take-off, and a weight of 16 tons. Using only its store of potential and kinetic energy, the bomber flies on to the point of bomb release, 5550 km. from the take-off point and 950 km. in front of the target. At this point, which is reached 1150 sec. after take-off, the velocity has decreased to 6000 m/sec, and the stationary altitude to 50 km. After the bomb release the weight is 10 tons. Then the aircraft goes into a turn and in 330 sec. goes through a turn-spiral 1000 km. in diameter until it has reached the direction for the return flight to the home base. During turning, the altitude is greatly decreased in order to develop the aerodynamic forces necessary for the turn. At the end of the turn path, the velocity is still 3700 m/sec and the corresponding stationary altitude is 38 km. The supersonic glide path in the direction of the home base goes over 5450 km. in 2600 sec and ends 100 km. before the home base at an altitude of 20 km. and velocity of 300 m/sec. Subsonic glide and landing are completed in customary fashion. The whole flight lasts 4755 sec.

Japanese Rocket Airplanes

The story of Japanese rocket airplanes concerns essentially the *Baka*

Me 163B (General)

Contractor: Messerschmidt	
Years	1943-45
Powerplant mfg.	HWK liquid rocket
Powerplant type	109-509A
Powerplant weight, lbs.	365
Thrust, lbs.	3300 max.
Propellants	C-stoff, T-stoff
Specific impulse, lb.-lb./sec.	180-190
Firing time, min.	4½ (full thrust), 10-12 otherwise, and possibly to 20 min. by using intermittent glide techniques.
Airplane length, ft.	20
Airplane span, ft.	32
Airplane weight, lbs.	9000-11,000
Payload, lbs.	1500
Range, miles	22 (after climb at 495 mph)
Altitude, ft.	40,000
Speed, mph	450-620

The Me-163 Rocket Fighter Program

Model	Velocity (max. mph)	Powered flight time (min.)	Rate of climb (ft./min.)	Engine No.

piloted but powered bomb. They had their *Shusui* version of the Me-163, developed by the Navy, and other piloted bombs referred to *(Kikka, Toka,* etc.), but the *Baka (Marudai)* was their key development.

The *Baka* fired its rocket immediately after release from the mother airplane, and upon burnout glided to target, or it could initially glide and employ rocket power in terminal approach. The bomb generally was launched at altitudes up to 5000 feet and perhaps six or seven miles from the target. It could fly 60 miles if launched from 27,000 feet. The pilots would enter the *Baka* from a hatch in the bomber, much as they do today in entering X-1-type rocket airplanes.

Baka was attached by a mounting lug and a series of slings. Like the *Natter, Baka* was of wooden construction, with fabric-covered plywood surfaces. The guidance system, however, was unlike the *Natter*. First, there was no initial autopilot operation, and second, the human guidance system was considered expendable. Three solid-propellant rockets propelled *Baka,* though the idea of using additional wing-mounted rockets was considered in view of ground launch. The solid charge was a monoperforated double-base powder. If the weapon was launched at maximum altitude of 27,000 feet, it glided for 52 miles at about 230 miles per hour at a glide angle of 5° 35″. Then its rockets took over and during the last three miles speed went up to more than 530 miles per hour. If rockets were used during steeper glide angle, velocities increased to over 600 miles per hour.

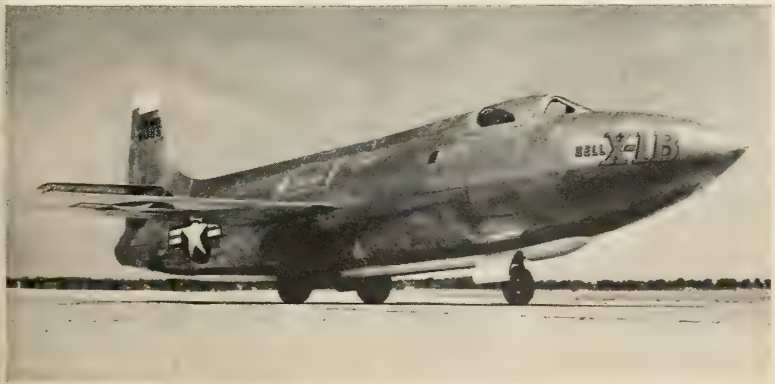
Baka was clearly a desperation weapon and one that could be employed only by a nation that could accept the planned expendability of life without even a one per cent chance of survival. While there were many ingenious features to *Baka,* its maneuverability was poor, and except during its brief powered flight, it was susceptible to enemy countermeasures. It seems certain that *Baka* represented one facet of rocket power airplane philosophy that is destined not to reappear.

American Rocket Airplanes

There is a certain resemblance to early American rocket-plane progress in the case of Germany. The former, like the latter, started off by outfitting gliders with solid rockets which had no important effect. For example, back in 1933, 86 solid rockets were supposed to have powered an airplane called *Spirit of Night.*

Similarly, the first practical rocket plane in this country was a military interceptor type, and it was developed under the cloak of secrecy during World War II. It was the Northrup MX-324 flying-wing design, with a span of less than 30 feet. Like the Me-163, it used a liquid engine, in this case the Aerojet XCAL-200, which produced 200 pounds of thrust on red fuming nitric acid and monoethylaniline. The pilot operated the plane while in a prone position, allowing a thin airfoil and permitting him to withstand considerable g-forces. The first flight occurred in July 1944 in California. Some models took off and landed on skids.

Once the feasibility of a rocket airplane was established, the Army Air Force approached Bell Aircraft in 1944 to apply the principle to the problem of designing a research airplane that could explore the transonic and supersonic flight regimes. At the time they wanted 800 miles per hour at 35,000 feet for two to five minutes of flight.



Bell first looked at a turbojet-rocket combination, then decided to use rocket power alone.

AAF went to Reaction Motors for its 6000-pound-thrust liquid-propellant rocket engine being developed for Navy use. This four-chamber engine could provide thrust levels of 1500, 3000, 4500 and 6000 pounds. Weighing 210 pounds, it occupied a space four and one-half feet long, with an elliptical cross section having an 18-inch major axis and a 13½-inch minor axis. Thus Bell Aircraft Corp. and Reaction Motors started off on the X-1 series of rocket airplanes that have since broken altitude and speed records and have accumulated vast quantities of data on manned flight at the aeronautical frontiers.

The RMI 6000 rocket engine compared most favorably with the German Walter 509s in that it developed nearly twice the thrust, yet weighed a third less.

The X-1 program has been widely discussed, so that here we shall content ourselves with salient details only. The X-1 weighed 13,400 pounds and was 31 feet long. The thickness/chord ratio was 8 per cent, and it weighed 4890 pounds empty. In 1946 some 10 glide tests were made from B-29s in Florida, and on Dec. 9, 1946, the first powered flight took place. The program was designed to gather data on drag, heat, stability and pilot physiological strain at high speeds and altitudes. The airframe was stressed for +18g and −10g. The following summarizes highlights of the X-1 program.

Like the X-1, the later (1951) X-1A was generally air-launched from specially modified B-29s (later B-50s). This model had the same RMI 6000-pound-thrust engine, but it could carry

The X-1B was designed to test the effects of aerodynamic heat on aircraft structures.

twice the propellants and featured a turbopump assembly rather than a gas-pressurization feed system. It was somewhat longer than the X-1, fired for over four minutes, and glided in for a landing at 150 mph. It was delivered to Edwards Air Force Base for test in November 1953, and within a month had reached 76,000 feet and Mach 2.5.

A second X-1A, with 4 per cent thickness/chord ratio and aspect ratio of 4 (versus earlier 6) was ready in early 1955 but exploded and was jettisoned from the parent plane. Along with the X-1A were the X-1B, X-1D and the currently used X-1E, last of the series. All operate on alcohol-water liquid-oxygen propellants. Essential data on these planes are presented in chart form.

The Douglas D-558-2 *Skyrocket* used the same 6000-pound-thrust engine as the Bell X-1 aircraft, and has the distinction of being the first plane in the world to reach Mach 2 in level flight. It was also the first plane to exceed 80,000 feet, its record being 83,235 feet (achieved by Bridgeman in 1953). It was outfitted with an air-conditioning system capable of maintaining cockpit temperature at 70°F during high-speed flight. Navy and NACA sponsored the research airplane.

In November 1947 the plane was ready and the first flight took place in February 1948, using only its Westinghouse jet-engine power. The rocket

The X-1E was the last of the X-1 series. It investigates high speed heat problems.

powerplant was still not ready. In February 1949 a combined rocket-jet flight was made. Later, air-launching techniques were employed, and in August 1953 an all rocket-powered flight was made which carried it to its record altitude. In November of the same year the record 1327-mph (Mach 2.01) flight was made.

Another Bell Aircraft development was the X-2, which was larger, heavier and faster than others of the X series. The history of the X-2 dates back to 1947. Delivery of the first unit was made during the summer of 1952. With small, swept, stainless-steel wings and a thick-walled nickel alloy fuselage, it was powered by a Curtiss-Wright XLR-25-1 variable thrust liquid-propellant rocket motor producing more than 15,000 pounds of thrust. The cabin was heat-insulated and all controls were power-boosted. The first of the X-2s exploded over Lake Ontario in May 1953, but the second went on to achieve aeronautical triumphs before it, too, was destroyed.

The X-2 used heat-resistant glass and heat-resistant alloys for all stressed parts. (At Mach 3, temperatures up to 350°C were expected.)

It made its first gliding flight in August 1954. Its first powered flight took place at Edwards AFB, California, in November 1955, and by July 1956 it had reached 1900 mph and an astounding altitude of 126,000 feet. Its record flight on September 27, 1956, brought it to Mach 3.1. On this flight, the "thermal barrier" research aircraft

German Rocket Airplanes

Airplane	Data	Comments
Antipodal bomber	Loaded weight: 220,500 lbs.; payload up to 672 lbs.; propellants: liquid oxygen/gas-oil; length: 91.8 ft.; thrust: 220,500 lb.	Project only; conceived in 1936, suspended in 1942; work performed at the Research Institute for Rocket Propulsion; designed to reach 93 miles altitude and 14,600 miles maximum distance from launch base.
Ar-234	With 45-second endurance, could reach 36,000 ft. in 3 minutes.	Made by Arado, with BMW turbojet and rocket.
DFS-194		High-speed interceptor investigated by A. Lippisch.
DSF-228	The 109-509A1 slated for this design.	A DSF-Siebel concept rocket reconnaissance craft. Prototype built and flown; was to have been operational up to 100,000 ft.
DSF-346	Two liquid rockets for Mach 2.6 speed.	Also DSF-Siebel design concept, scout bomber; initially a research type.
He-176	Walter liquid rocket on Heinkel airframe.	First flew in 1938; not operational.
Julia, P-1077	Thrust variable from 440 to 3750 lbs. over short periods; loaded weight: < 5000 lbs.; empty weight: 2000 lbs.; range: 40 miles; velocity: 500 mph.	Also a Heinkel development, it was a VTO type with four 2600-lb.-thrust, 10-sec. boosters plus a Walter liquid sustainer. Rate of climb about 40,000 ft/min.; skid landing. It was not built.
Ju-248	Approx. 26 ft. long; weight: 11,700 lbs.; range: approx. 100 miles; velocity: 620 mph; maximum thrust: 4430 lbs. Designed to reach 40,000 ft. in 3 minutes.	Used 109-509C1 liquid rocket engine; slimmer than the Me-163; a target defense plane. Only one was constructed.
Me-163B	See separate chart.	See separate chart.
Me-163C	Weight: more than 11,000 lbs.; designed for 590 mph, 52,000 ft. altitude. Endurance of 15 minutes at 500 mph.	A mid-wing monoplane, it evolved into the Me-262.
Me-262	Weight: 18,000 lbs.; thrust of liquid rocket: 2750 lbs.	BMW-718 rocket engine with BMW or Jumo jet engines; also designed to use one or two Walter rockets.
Me-263	Length: 25.9 ft.; span: 31.3 ft.; maximum thrust: 4430 lbs.; weight: less than 12,000 lbs.; velocity 620 mph (max.); rate of climb: 13,800 ft/min.	Used 109-509C1 engine; glide-tested only, however. Was a pure rocket fighter design. Development started by Junkers, turned it over to Messerschmidt. Ju-263 designation also seen.
Natter, BP-20B	Length: 18.75 ft.; span: 10.5 ft.; climb rate: 35,000 ft/min.; 2.2 g acceleration; 12 mile radius of action; cruising speed: 496 mph (max. at 16,000 ft.: 620 mph).	Had four SR-34 solid boosters (109-533 diglycol) by Schmidding, and a liquid Walter rocket (recoverable). Pilot rode forward of wings. Largely wood construction.
P-1104	Rate of climb: 39,000 ft/min.	Messerschmidt design, pure rocket interceptor. Mk-108 armament visualized.
Ta-183		Focke-Wulf jet/rocket, twin-boom airplane.
Volksjaeger, He-162	Design endurance: 45 minutes.	Heinkel rocket fighter project.
Walli, EF-127, -128	Length: 26.4 ft.; span: 20.6 ft.; weight: < 6500 lbs.; range: 60 miles; speed 630 mph. Thrust was variable from 440 to 3750 lbs.	A target defense fighter, not built; rocket engine only, i.e., not jet auxiliary.
Zeppelin Ram Design		To have been used for ramming; solid-propelled, like the Japanese Baka.

This variable-thrust rocket plane has reached the highest velocity and altitude to date.

crashed, due probably to loss of directional stability. Pilot Apt was killed.

The X-1E and the X-2 do not end the American rocket airplane research program. There are apparently at least two others. The first, the rumored Douglas X-12, is somewhat indefinite, but is supposed to be capable of reaching Mach 5, a range of 500 miles, and an altitude of 140 miles. It may be a Navy-DNR project. Details on the second, the North American X-15, are shaping up rather rapidly.

The X-15 is an Air Force-, Navy- and NACA-sponsored project and will be designed to probe two main unknowns: the effects on airplane and man of Mach 5-6 flight, and the effects on airplane and man of flight 100 miles or more above the earth's surface, including specifically heating, control, stability and re-entry.

What we are to see, in effect, is a manned spaceship, powered by a Reaction Motors 60,000-pound-thrust rocket engine and capable of operating in the void. An interesting fact about the airplane is that it is considered quite safe, despite the frontier regions in which it will fly. It has been thoroughly "human engineered," and aeromedical experts have labored on the project side by side with the aeronautical engineers. It will probably make its first test glide from the Edwards AFB flight test center in 1958.

The X-15 will have to be versatile to explore successfully a variety of speed regimes at a variety of altitudes. Top speeds will presumably be attempted at extreme altitudes—100 miles or so. Re-entry will be critical, and it is obvious that aerodynamic glide descent techniques will be employed. Results from X-15 flight testing are sure to be directly applicable to one of the most important facets of astronautics—descent onto planets with atmospheres.

Oddly enough, the United States has seemed to pay little attention to the rocket-powered military aircraft. Nevertheless, in the early 1950s, the development of an experimental rocket-turbojet interceptor airplane was sponsored by the Air Force. It was designated the XF-91 and was handled by Republic Aviation Corp.

It is noted mainly that it was the first U.S. rocket-powered combat-type fighter to exceed the speed of sound. This it did late in 1952 on a flight out of Edwards AFB. Test flights started in 1949, the first on May 9.

XF-91 had two powerplants, a GE J-47 developing 5200 pounds of thrust, and a Reaction Motors 6000-pound-thrust liquid rocket of the same type used on the Bell X-1 and Douglas D-558-2 research airplanes.

An interesting feature of the plane was the inverse taper on the swept-back wings, which reduced wingtip stalls due to lift loss. The wing also showed variable incidence, which allowed a high angle of attack for take-off and landing and low angle of attack for level operation. Pressurization and refrigeration were provided.

There are known to be other rocket airplane projects in the United States but details are not available. A rocket engine recently exploded during test at Reaction Motors, killing or injuring both RMI and Chance-Vought engineers. This set off new rumors about a suspected rocket airplane that may be under development by the two firms.

The Air Force has already predicted manned flight at Mach 10 within 10 years, which is double the speed assumed for the X-15. Rocket engines will gradually increase in power, and we may hear more of the turbo-rocket motor. Marquardt has one under development where the efflux of the rocket engine is passed through a turbine driving a compressor. Ram air is compressed and, by suitable ducting, is made to join the turbine exhaust, providing thrust. Aerojet-General has reported making studies of a 2000-mph commercial airliner which, it feels, could be available within 20 years.

This rocket-powered commercial airliner proposition was well publicized about a year ago in a series of articles by Dornberger. He visualized a two-stage rocket glider which would travel from 7000 to 11,000 mph at an altitude of between 25 and 35 miles. It would slow to 2700 mph for re-entry, and essentially would be automatically controlled.

Characteristics of Baka

Length (ft., in.)	19' 10"
Span (ft., in.)	16' 5"
Wing area (sq. ft.)	64.7
Wing loading (lbs./ft.²)	70
Weight (lbs.) (with 120 lb. pilot)	4535
Weight, warhead (lbs.) (with 1135 lb. explosive)	2645
Weight, airframe	1000
Weight, propulsion unit (lbs.)	768
Length, propulsion unit (ft., in.)	6' 6"
Thrust (lbs.) (max.) (average: 1500)	4500
Average firing time at 60° temperature (sec.)	~ 10
Velocities, considering maximum total horizontal range case (mph)	
1 rocket fired	350
2 rockets fired	455
3 rockets fired	535
(Note: Level flight speeds)	

French Rocket Airplanes

In the west France can be considered the European leader in the application of rocket power to airplanes, and is apparently the world leader when it comes to rocket combat-aircraft progress.

Her outstanding development at the moment is the *Trident* II SO.9050 airplane, which has been so successful that not only the French manufacturer, but German, Dutch and Belgium firms, have recommended that their governments adopt it as an interceptor.

The II model was preceded by the

The Fairey DELTA I is the British entry in the rocket research airplane field. Craft utilizes a liquid rocket for assisted takeoff and a conventional turbojet for cruise.

experimental SO.9000 *Trident* I, which in May 1955 reached supersonic flight in climb. Its main powerplant was a three-chamber SEPR481 (earlier 25) liquid-rocket engine with MD-30 *Vipers* on the wingtips as auxiliary jet engines. Both I and II were conceived by French designer Servanty, and the first "jet only" *Trident* I flight was made on March 2, 1954 with Jacques Guignard at the controls. Charles Goujon took it on its first rocket flight early in September of the same year. Though the rated thrust was about 9900, it actually built up 10,500 at sea level and 11,500 pounds at 40,000 feet.

The plane features short, thin, straight wings with no ailerons. It is light and fast, being designed for Mach 1.6 flight. Highly maneuverable, *Trident* I's rockets can be fired or turned off at will, both simultaneously or in sequence. The SEPR481 is believed to have undergone over 1000 ground tests and 125 flight tests during the development period. Specific impulse is 208-16 lb./sec. at high altitude.

SO.9050 *Trident* II is very much like *Trident* I. Apart from improved lift and aerodynamic considerations and a slightly shorter span, there is little to distinguish the two. *Trident* II uses two wingtip *Vipers*, but is shifting to Turbomeca *Gabizos* with afterburners at the present time. It has a two-chamber furfuryl alcohol-nitric acid SEPR631 rocket engine developing 6600 pounds of thrust. It makes use of honeycomb material and metal-to-metal bonding, is light, fast (has reached Mach 1.9 already and is designed for Mach 2 flight), and is operational at 50,000 feet. (It has attained 59,000 feet.) The plane is not area ruled.

This single-seat interceptor was first flown with jets only in July 1955 at Istres, near Marseilles, and in December Goujon took it on its maiden rocket flight. Since then more than 100 test flights have been made successfully. The plane is attractive to Europeans since it is simple, easily and cheaply produced, can be serviced rapidly, and can land on and take off from poorly prepared, small airstrips. (It needs about 1500 feet, and lands at 100 mph.)

It is a high-altitude interceptor that can patrol for a considerable time before making its supersonic close-in. It is reported capable of reaching 50,000 feet in two-and-one-half minutes. At the present time its ceiling is governed by pilot survival considerations only. The cabin is pressurized and has a canopy that can be jettisoned together with an ejector seat. Ten are on preproduction order by the Air Force. Production facilities are at Courbevoie.

Sud-Est's (now Sud) SE.212 *Durandal* may be dropped in favor of mass producing the *Trident* II. This mixed-engine interceptor first flew from Istres on April 20, 1956, with Pierre Maulandi at the controls. Like the *Trident*, delta-wing *Durandal* is a light, anti-bomber airplane that can make a sustained supersonic climb without even utilizing its rocket. More than 100 flights have been made.

Power is given by a SNECMA *Atar* 101-G-21 jet building up 9900 pounds of thrust and an SEPR rocket engine developing 3300 pounds. *Durandal* weighs about 12,000 pounds and has an announced speed in excess of Mach 1.5. Its armament consists of air-to-air homing missiles. A new, faster *Durandal* IV with an *Atar* 9 13,230-pound-thrust jet plus rocket is now being developed.

The *Espadon* SO.6025 (and 6026) jet-rocket airplane was used as a test bed for *Trident*'s rocket engine. At least 60 flights with the SEPR251 were successfully made, the first on June 10, 1952. Thrust was 3300 pounds, firing time 3.25 minutes. *Espadon* led directly into the current crop of French rocket airplanes, and was the first rocket plane developed in Europe since the war (Russia excluded).

Another mixed light interceptor is the *Griffon* 1500 (ex *Guepard*) of Nord-SFECMAS. This has an *Atar* 101-G with afterburner and two 2400-pound-thrust rocket chambers. It weighs 9000 pounds, has a Mach 1.3 velocity and first flew in September 1955. Nord's *Harpon* is a similar type. Dassault's MD-550 is a delta-wing airplane with *Viper* jets and an SEPR

X-1 History

1946	First powered flight (speed: Mach 0.795 at half throttle)
1947	Speed of sound exceeded in level flight (by Capt. C. F. Yaeger)
1948	Maximum speed of 967 mph attained
1949	Take-off from ground (2300-ft. run at full power; plane reached 23,000 ft. in 100 sec.)
1949	Maximum altitude attained (73,100 ft.)
1950	Retirement of X-1 to National Air Museum* in August

*Two other X-1s built, one of which had a turbopump assembly and exploded in November 1951.

U.S. Rocket Airplane Velocity Records

Plane	Velocity record
X-1	First to reach Mach 1
D-558-2	First to reach Mach 2
X-1A	First to reach Mach 2.5
X-2	First to reach Mach 3
X-15	Designed to reach Mach 5-6

The USAF-NACA-Bell X-1 Series

Plane	Remarks
X-1	See separate chart.
X-1A	Speed record set in Dec. 1953; altitude in June 1954. Air-launched at > 25,000 feet; duraluminum construction; ejection seat; tempered glass windshield.
X-1B	Like X-1A, weighs about 18,000 lbs; carries 1000 lbs. of special instrumentation; used from 1955 to determine effect of heat on structures.
X-1C	Cancelled.
X-1D	Destroyed in August 1951.
X-1E	Undergoing test. High speeds expected due to lighter airframe, less volume taken up by turbopump; heat studies being carried out.

liquid-rocket installation. Capable of Mach +1 flight, it first flew in Bretigny in May 1955. Its armament consists of air-to-air missiles and 30-mm cannon. This plane is better known as the *Mirage* I.

Mirage II used two Turbomeca *Gabizos*, plus its two-chamber, 2400-pound-thrust SEPR rocket. *Mirage* III is today's version, having a SNECMA *Atar* 101-G with afterburner and the liquid SEPR rocket rated at 3300 pounds at sea level. Turbine cooling is achieved by using a methyl alcohol-water combination to cool generator gases.

Flight testing of this interceptor and tactical support craft began in November 1956. Area ruled, *Mirage* III is 35 feet long, has a 26-foot span, and weighs 11,000 pounds. Its armament can consist of 30-mm cannon, air-to-air rockets, bombs, napalm, and so forth. It has a long-range search and missile-control radar, can be zero-launched and land on skids, or it can operate conventionally from small, poorly prepared strips. It flies between Mach 1.5 and 1.7. *Mirage* IV will be outfitted with an *Atar* 9, and should operate in the Mach 2 region. The SEPR66 rocket engine powering the *Mirage* has seen very extensive ground and flight testing.

The French Air Force may order "hundreds" of the III model.

British Rocket Airplanes

Despite the seemingly obvious requirements for extremely rapid manned interceptors, Britain has not given as much attention to rocket airplanes as France. Back in 1950 the Ministry of Supply backed a Fairey VTO project which employed not only a two-chamber *Beta* 1800-pound-thrust liquid sustainer but two solid boosters developing a total of 1200 pounds thrust. The announced object of this program was to determine the practicality of vertically launching interceptors at low accelerations.

With a delta-wing configuration, it featured autopilot control, correcting the vehicle's path by deflecting the thrust line of the upper chamber. The VTO was presumed to be a test vehicle for an advanced FD-1 research airplane.

Other than this VTO project, the British are rumored to be considering a rocket bomber, though no details have been made public. The Avro.720 rocket-jet interceptor project was cancelled some time ago during an economy move. The major current development program involves the Saunders-Roe S-R.53 (a competitive design to Avro.720), about which a number of details are known.

Before going on to the S-R.53, however, it is well to stop long enough to mention briefly some of Britain's rocket engine developments. In discussing them, the question again arises: "When, exactly, do you have a *rocket airplane* and when do you merely have a *rocket-boosted airplane?*"

Generally, it is felt that if the engine is permanently installed and is used for purposes other than just help-

French Rocket Airplanes

Air-plane	Desig-nation	Manu-facturer	Liquid rocket engine thrust (lbs.)	Velocity (Mach No.)	Remarks
Durandal	SE.212	Sud (ex-Sud-Est)	3300 x 2(?)	> 1	Delta-wing; bomber destroyer; supersonic in climb
Espadon	SO.6025 (6026)	Sud (ex-Sud-Oeust)	3300	> 1	Test airplane leading to Trident; post-war Europe's first rocket airplane; SEPR 25 then 251
Griffon	1500	Nord/SFECMAS	4800	1.3	Has Atar with afterburner; weighs 9000 lbs.
Harpon		Nord	4800	> 1	Similar to Griffon
Mirage I	MD-550	Dassault	3300	∧ 1	Delta-wing; first flew May 1955; armed with air-to-air missiles; has Viper jet.
Mirage II		Dassault	2400	> 1	Like I, with Gabizo jet.
Mirage III		Dassault	3300	1.7	Like I, with Atar 101-G jet with afterburner; area ruled; strong competitor to Trident II.
Mirage IV		Dassault		2	Like I, with Atar 9; not yet ready.
Trident I	SO.9000	Sud (ex-Sud-Oeust)	9900	> 1	SEPR 481 rocket & Viper wing tip jets; experimental
Trident II	SO.9050	Sud (ex-Sud-Oeust)	6600	1.9	In pre-production; like I, with shorter span; Gabizo jets; SEPR 631 rocket engine; may become standard NATO interceptor; reached 59,000 ft.

British Auxiliary Power Rocket Engines

	Screamer	Snarler
Designation	A.S. Sc. 1-2	A.S. Sn. 1
Developer	Armstrong Siddeley	Armstrong Siddeley
Weight (lbs.)	470	215
Chambers (No.)	1 (earlier, 2)	1
Thrust (lbs.)	800-9500	700-2000
Propellants	liquid oxygen/aviation gasoline/water	liquid oxygen/methyl alcohol/water
Specific impulse (lbs.-lbs./sec.)	208-217	200-200
Chamber pressure, psig	600	280
Remarks	First test, 3-54; first flight test, 12-55. More than 1300 firings have occurred. Program suspended in 1956.	Tested in 1950 on P-1072 interceptor. Can fire 3 minutes at full thrust; prototype flown, 11-47; over 650 firings. Program suspended in 1952.

British Rocket Airplanes

Name	Manufacturer	Powerplant(s)	Remarks
Avro-720	Avro	Liquid rocket plus turbojet	Projected rocket-jet interceptor; cancelled.
Fairey VTO	Fairey	Liquid rocket plus solid boosters	VTO launch test vehicle; possibly for FD-1 research airplane.
S-R.53	Saunders-Roe	Viper jet plus Spectre rocket (liquid)	Now being flight tested; called a recoverable booster for air-to-air missiles.
S-R.177	Saunders-Roe	Liquid rocket	Project only.

ing take-off it should be thought of as an integral part of the airplane design, and not only an added feature.* The RAE *Alpha* rocket engine, for example, was the main engine for a Vickers transonic airplane model, while *Beta* I and II, later, were also used on the aerodynamic research vehicle. *Gamma, Scarab, Scorpion, Sprite* and *Super Sprite* engines are ATO units. The *Super Sprite,* incidentally, is the first British aircraft rocket engine to go into production.

Both the AS.1-2 *Screamer* and the AS.1 *Snarler* are primarily auxiliary powerplants providing surge speed for fighters, and can be stopped and started at any altitude. *Screamer* has been successfully used on the *Meteor* 8, and was considered the successor to the *Snarler* (which was flight tested in November 1950 in the Hawker P-1072). That *Screamer* was cancelled last year despite the fact that it reached the flight clearance stage indicates that the sponsoring Ministry of Supply decided to use peroxide rather than liquid oxygen for its rocket interceptors.

The delta-wing, mixed-power S-R.53 interceptor has been described as a "recoverable booster" for air-to-air missiles, as well as "the most important link in progress between the current orthodox fighter and the unmanned ground-to-air missile of the future." A Saunders-Roe development, its 1750-pound-thrust *Viper* jet engine is a product of Armstrong-Siddeley, and its *Spectre* rocket booster is from de Havilland.

The *Spectre* is presumably an outgrowth of the *Sprite* and *Super Sprite* programs, and has performed well in the S-R.53 application. It is interesting to note that the ratio of jet to rocket propellant can be varied according to the tactical situation.

The *Spectre* rocket engine is the main powerplant of the S-R.53, and not an auxiliary. It is apparently the first British airplane that can really be considered rocket powered.

Little additional information is available on the plane. Its rate of climb is rumored to be 40,000 feet per minute, and it has a large quantity of avionics for automatic control. The S-R.53 first flew at the Aeroplane and Armament Experimental Establishment, Boscombe Down, in May 1957, and can take off from, and land on, small runways.

Reports have it that the S-R.53 will evolve into the S-R.P-177, an advanced rocket interceptor, though there is apparently no official Royal Air Force support for the project. It, too, presumably will employ a *Spectre,* but a *Gyron Jr* jet engine is expected to be used (a scaled-down 15,000-pound-thrust *Gyron*).

It is also probable that the English P.1 will eventually be outfitted with a Napier *Scorpion* rocket engine, making it, too, a mixed fighter. *Scorpion,* as it now stands, has two chambers producing 2000 pounds of thrust each on kerosene or wide cut gasoline. At the present time it provides JATO power for the *Canberra* bomber.

One could consider rocket-powered helicopters, such as Saro's Skecter *to be rocket airplanes. This model has Napier HTP rockets in the blade tips, much like Reaction Motors' ROR (rocket on rotor) projects in the U.S.*

Russian Rocket Planes

Airplane	Velocity	Remarks
Yak-21	700 mph	21-ft. span, 12,000-lb. weight. Auxiliary rocket powerplant (liquid).
La-17	Mach 1	36-ft. span, 16,000-lb. weight. Auxiliary rocket powerplant (liquid).
I-1	1700 mph	Rocket interceptor-type research aircraft. Altitude: 100,000 ft.
I-2	< 800 mph	Liquid rocket VTOL interceptor, with less than 8 min. flight time. Armed with air-to-air missiles, 37-mm cannon.

Russian Rocket Airplanes

We know less about Russian rocket airplanes than we do about Russian missiles. Yet we are fairly certain that Russia has made considerable progress in applying rocketry to aircraft, and it seems likely that German wartime efforts provided the basis for this trend.

There are many indirect indications of Russian interest in rocket airplanes. As Dr. Albert Parry has indicated, the Russians are trying to find out more about "weightless airplane" research, and "non-weight aircraft." It was pointed out that reference was made to work on gravitation in the United States and the Canadian Avro "flying disc." There is also evidence of Russian research on the problems of manned re-entry into the atmosphere in rockets.

For years there have been persistent rumors that the Russians were adapting the Sänger antipodal bomber design to their uses. A T-4A designation has been mentioned, with a range of from 4000 to 10,000 miles. Its apogee has been guessed to be in the neighborhood of 120 miles. It would hold a single pilot, according to some reports, though others hold it would be pilotless.

The Russians have admitted they are thinking about manned intercontinental rockets. On Sept. 20, 1830 hours Huntsville time, the author picked up an interesting broadcast from Radio Moscow. Missile expert Sternfeld, speaking on the program SCIENCE AND ENGINEERING IN THE USSR, devoted 10 minutes to a three-stage Moscow-New York manned rocket with an apogee of 750 miles. Poor reception did not permit further details to be recorded, though cut-off altitudes were apparently mentioned.★

Two seconds to "FIRE"...the time when your instrumentation cables must work

Are you responsible for any of the equipment involved in scenes of this kind? Any of the instrumentation or telemetering devices?

If so, you well know how little can be left to chance when a $100,000-plus pre-dawn "shot" is scheduled.

Even minor cable trouble at a time like this can be crucial and costly, especially if it happens on the equipment involved for which *you* are responsible.

That's why it's important for you to insist on electronic cables with *maximum built-in reliability*.

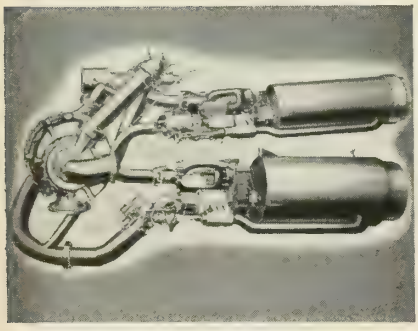
Quiz yourself on cable

Here's how to get this kind of reliability. Ask yourself these questions about the cable that's to go into your own equipment:

1. Who is the cable supplier? Has he:
   a. Thorough knowledge of electronic wiring problems?
   b. Engineering and research skill in developing special cable?
   c. Complete facilities for producing custom-built or specification cable?
2. Are his cable conductors full-size, uniformly annealed and precisely stranded?
3. Are his insulations and coverings uniformly applied compounds that have proved workable, dependable?
4. Can he supply those newly developed materials that might be needed?

You'll find all of these qualifications met in full measure by Rome Cable

Millions of feet of Rome wire and cable have already been installed in electronic gear for military and commercial uses. More is ordered every day.



When you require cable that must not fail—or which must meet unusual specifications—we can very probably help you. Simply contact your nearest Rome Cable representative—or write to Department 422, Rome Cable Corporation, Rome, N. Y.

Higher and faster than ever before

World's first throttleable rocket engine is one of a group of Curtiss-Wright powerplants and missiles capable of several times the speed of sound.

The Curtiss-Wright Rocket Engine would fit under the hood of your car, yet delivers a thrust equal to the power that drives a Navy cruiser at high speeds . . . a thrust that has flown man higher and faster than ever before. And this record-breaking power is controlled, by the hand of the pilot, for the first time in history . . . doesn't burn itself out in ordinary rocket fashion.

The pilot can control his thrust through a wide range, start or stop it at will, conserve fuel or use it all in one prolonged burst. Operating at speeds near the thermal barrier he can explore the advanced problems of supersonic and hypersonic flight.

The Rocket Engine is one of a group of Curtiss-Wright powerplants and missiles capable of several times the speed of sound...a group that includes also the Ram Jet... and the HTV rocket which reaches supersonic speed a fraction of a second after launching.

Human Factors in Space Flight

By Arthur Kahn
Westinghouse Electric Corp.

SINCE THE END of World War II and the accelerated development of rockets and propellants, there has been a renascent interest in the engineering problems of space flight. This has been heightened by the ascent of *Sputnik*.

In the main, most of the effort has been concentrated on the ability to function in a weightless environment and on the effects of high levels of acceleration. Much of this effort has been to determine the limit of the human's endurance rather than his capacity to perform tasks in this environment.

Originally, scientific interest in space flight had been well formed prior to World War II. Oberth's book WEGE ZUR RAUMSCHIFFAHRT (THE WAY TO SPACE TRAVEL) took up many of the technical problems of space travel. Oberth incorporated many of his ideas into a spaceship that was used in a German movie of 1929-vintage entitled FRAU IN MOND (WOMAN IN THE MOON).

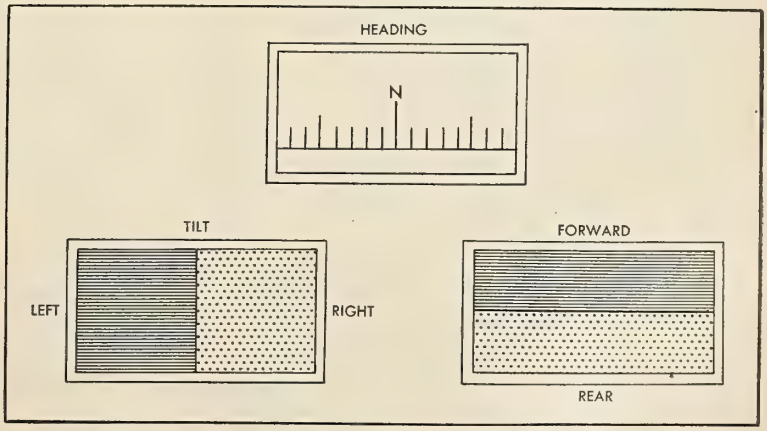
Until recently, Oberth's work was the most comprehensive source of space flight data. Much of this book and other material considered the engineering problems involved in constructing a spaceship and the propellants required for developing sufficient thrust to drive the vehicle beyond the earth's gravitational field. There is little mention of controlling the vehicle in flight, in landing on the moon and on the return trip to earth.

Despite this interest in manned space flight there has been little interest among engineers in providing solutions to the human factors problems. Oberth's most recent book, MAN INTO SPACE, devotes little space to the human factors problems other than to record the fact that these problems are being studied at the Department of Space Medicine, School of Aviation Medicine, at Randolph Field.

He indicates the crews for these vehicles must be selected in accordance with rigorous criteria which are not mentioned. With the present intensified interest in space flight, it is necessary to examine some of the problems in which the operator's requirements will determine engineering needs.

The problems involving the operator or operators of a manned vehicle traveling beyond the earth's atmosphere can be divided into four major categories: ecological, perceptual, personality and human engineering.

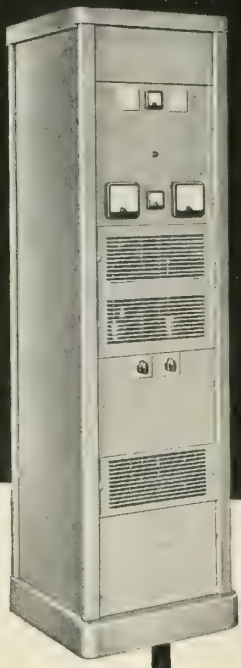
Physical Orientation



The ecological items are essentially aeromedical problems. Many of these problems now confront the equipment designer in high-altitude flight. The extent to which present operating conditions are akin to space have been indicated by Strughold in using the term "space equivalent" to denote those altitudes at which the human operator could be exposed to conditions within the earth's atmosphere that are similar to those in space. It is necessary to provide a full pressure regime beyond 50,000 feet. Blood "boils" at the vapor pressure that exists at 66,000 feet or 12 miles.

At nine-and-a-quarter miles, the amount of oxygen in the atmosphere is practically zero. At 15½ miles, it is impractical to pump air into the crew's quarters because the air is too thin. It also contains ozone, a poison. The environment must be controlled within reasonable limits by maintaining given pressure levels, humidity and temperatures as well as gaseous content.

A major problem is the removal of gaseous wastes of the respiratory process. In the earth's atmosphere, the CO_2 given off by humans is absorbed by plants which in turn give off the oxygen that man must have to survive.



Recent reports from the School of Aviation Medicine at Randolph Field suggest that such a closed system is feasible and can be incorporated into a space vehicle. If this closed system cannot be developed, oxygen must be either carried in the vehicle or somehow manufactured on board. Similarly, provision must be made for removing the CO_2. Protection also must be provided against cosmic radiation.

The problem of temperature and humidity control are related. Although man can withstand temperatures of over 100° for periods of time, he has an upper limit of 110°F. It will be necessary to maintain the temperature at a much lower level, in all probability about 80°F, if he is expected to perform tasks that require accurate computation and difficult decisions. Proposed tilt and heading indicator for ease of reading by crew.

6 cps to 100,000 cps at
1,000 WATTS CONTINUOUS DUTY
...with the new Genisco-Savage high-output amplifiers!

Here's the new line of quality, high-output amplifiers you've been waiting for! All seven models feature high power output, low distortion, exceptionally high reliability and stability, and excellent output voltage waveform.

The Model KLF, shown at left, is particularly useful as an exciter for vibration testing equipment and as a variable frequency power supply for a multitude of production and laboratory needs. It will operate *continuously* with an output of 1,000 watts from 6 to 2,000 cps.

Components of all Genisco-Savage Amplifiers are mounted on 19″ vertical panels to facilitate easy inspection and maintenance. Quick-release grill covers make all tubes readily accessible from the front. Numerous built-in safety features protect the equipment from operator errors.

Two New Shake Tables Available The new Model V1000 Genisco-Savage Shaker features a very light moving coil assembly, high thrust-to-weight ratio, automatic impedance matching, and an excellent output waveform. A continuous alternating thrust of ±600 lbs. is produced at 1,000 watts control power. Thrust can be increased to ±750 lbs. peak by use of a blower (Model V1000B). Both models have been stress-tested to withstand continuous operation at accelerations of 100 G's.

Seven models—rugged enough for production line testing; versatile enough for almost all laboratory needs.

The Genisco-Savage Model V1000 Shaker

BRIEF SPECIFICATIONS	MODELS						
	BM2	DM2	KM2	10K	KM25	KLF	KRF
Output	250 w at 50 or 100 v	500 w at 50 or 100 v	1000 w at 50 or 100 v	10,000 w maximum	1000 w at 50 or 100 v	1000 w at 50, 100, or 200 v	1000 w at 25, 50 or 100 v
Frequency Range	50 to 10,000 cps at 250 w	50 to 10,000 cps at 500 w	50 to 10,000 cps at 1000 w	40 to 10,000 cps at 10,000 w	50 to 10,000 cps at 1000 w	6 to 2000 cps at 1000 w	5 to 100 kc at 1000 w
Sensitivity	0.036 v at 600 ohms	0.04 v at 600 ohms	0.1 v at 600 ohms	0.16 v rms at 600 ohms for 10,000 w output	0.1 v at 600 ohms	0.05 v at 600 ohms	0.5 v at 600 ohms
Distortion	1% at 250 w, 1000 cps	0.75% at 500 w, 1000 cps	Less than 0.75% at 1 kw, 1000 cps	Less than 3% at 10 kw, 1000 cps	Less than 0.75% at 1 kw, 1000 cps	Less than 5% at 1 kw, 10 to 1000 cps	

Price and delivery of both amplifiers and shakers are exceptionally good. For complete specifications and prices send for the new four-page illustrated brochure.

search indicates that the optimum temperature will depend on the amount of clothing the operator wears, as well as upon the vapor pressure of the water vapor. It is obvious that it will be difficult to satisfy these requirements because at the beginning of space at about 500 miles from the earth, the temperature is about 900°K.

Psychological Orientation

The personality problems develop from factors in the individual's background. Such obvious problems as claustrophobia, inability to cope with fear of the unknown and social isolation must be considered.

At the present time the Air Force is sponsoring a study on these types of problems at Lockheed-Marietta. Beyer and Sells have discussed some of these problems in their article, "Selection and Training of Personnel for Space Flight." Clark and Graybiel have suggested that in some instances the feeling of detachment from earth may become a problem, particularly where the crew has little to do.

Many similar problems are being encountered in the selection of submarine crews and in the selection of men to man radar and weather stations in the DEW line. These problems emphasize the need for what has come to be known as small group research such as that conducted on combat assignments by the Air Force Personnel and Training Research Center.

Perceptual problems involve the capacity to "visualize" space as a kinematic environment with objects moving about the vehicle. The operator "builds up the space picture" from various sources of information that will be available to him. This is related to the problems of human engineering.

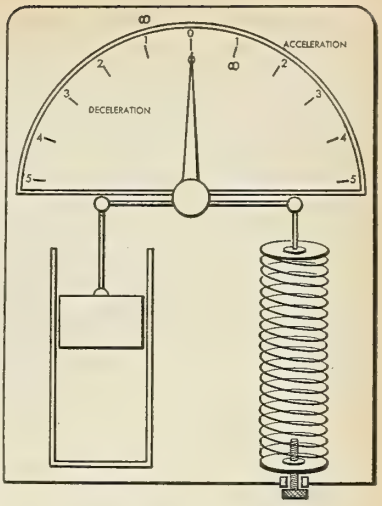
Human engineering factors should be considered in the construction of the various devices and displays that the crew will use to control the vehicle and its internal environment as well as the various equipment the crew may be required to wear.

The displays and controls for a spaceship can be divided into the following groups: (1) ecological systems (mechanisms for controlling the internal environment of the crew compartment), (2) navigation displays and control systems, (3) communication systems displays and controls, (4) displays for showing altitude of the vehicle and propellant conditions and controls for changing the altitude of the vehicle, and (5) the amount of propellant used.

The displays of the ecological system can be specified rather simply: pressure gauges and temperature and humidity gauges. The displays will also show the condition of the equipment maintaining the environment.

If the conventional pressure, temperature, humidity and rpm indicators are used, it would be quite an undertaking for the pilot and co-pilot to monitor all these displays in addition to performing some of the other tasks of navigation, communciation and vehicle control. Obviously, there is need for a display system that will present much of this information in such form that the operator will not be required to integrate various sources of information. The many problems of this one aspect of space flight must be attacked immediately if solutions are to be available when the instruments for these spacecraft are designed.

In developing the navigation displays, the methods used for navigation must be considered. Conley[1] suggests what he calls "V.S.A.—very simple astrogation." In this system, he requires the crew of a spaceship to make calculations of the flight time on a trip to the moon and position the moon at the end of the time of flight, making allowances for the sun's gravity drift.



He then requires the pilot to aim the craft at this point. This procedure requires exact knowledge of the position of the craft and a representation of this position on an appropriate display. The design of such a display will require the scaling of the solar system's dimensions into meaningful displays within the aircraft's confines.

Since the available displays for navigation are somewhat unsatisfactory for high-speed high-altitude flight, much work will have to be done in order to develop displays that will be easily interpretable without the integration of information from other instruments. The ability and the ease with which the pilot will be able to "visualize" the space picture about him will depend on how much effort is put into the development of the display.

The problem of communication between the home base and the spaceship is one that must be considered. Clark in his book INTERPLANETARY FLIGHT indicates that it is possible to transmit speech to a spaceship 10 million kilometers away from earth with present-day equipment using a frequency of 3000 megacycles per second and an aerial of one square meter on the spaceship and 100 square meters at the earth's station.

The only problem would be the time lag due to the finite speed of the radio waves, since it takes 1.3 seconds for a signal to reach the moon from the earth. This problem might be circumvented by storing the complete message

[1] J. Space Flight, *Vol. 2, No. 2, 1950.*

Acceleration-deceleration meter.

before reading it out through a speaker system.

Other than the lag problem, the communication problems are no different than those that plague present voice communication systems. Increasing signal-to-noise ratio, cutting down interference and increasing the intelligibility of spoken messages are a few of the present-day problems that will be encountered in spacecraft communications unless solutions are obtained.

The foregoing paragraphs have not covered the problem of control of the space vehicle. Conley[2] has suggested an instrument that might be comparable to the combination of a gyro horizon and a heading indicator in conventional aircraft. Fig. 1 shows this instrument. It is aligned with the vertical axis of the vehicle. It is assumed that the pilot is seated on the same axis.

The instrument gives the angle of the ship to the vertical and to the horizontal as well as the direction of the spacecraft. He has also suggested a design for an acceleration-deceleration meter.[3] This instrument is shown in Fig. 2. He suggests that three of these instruments be mounted so that the sliding tube of the weight of one tube is aligned with each axis of the space vehicle.

The scale is so designed that on the earth's surface, gravity is unity or zero on the scale. If the spaceship were on the surface of the moon, the operator would require three meters to know what accelerations were acting on the ship and himself, plus additional meters for angular accelerations. This information is vital to his assuming a

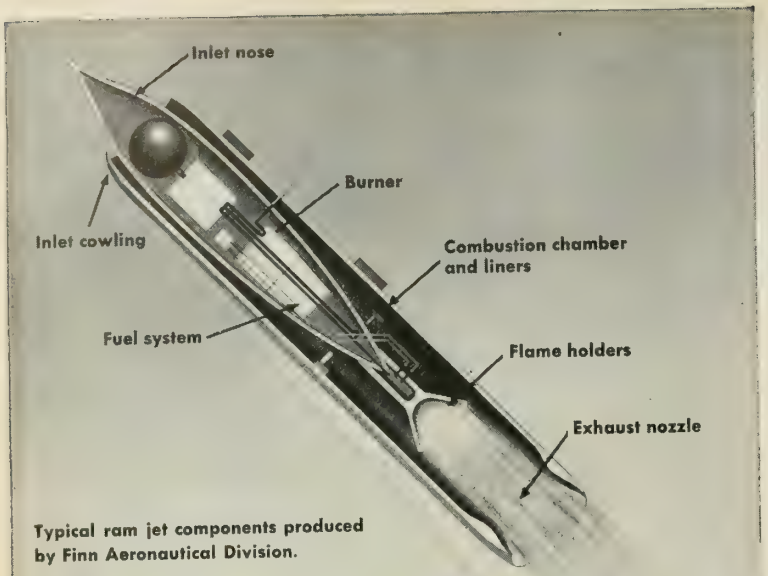
[2] J. Space Flight, *Vol. 3, No. 3, 1951.*

[3] *Ibid.*

position that will minimize the effect of acceleration. He must have it in some form. With this projected system, he would be required to integrate this information—altitude, position and accelerations on the vehicle.

Conley's work indicates the difficulties that will face the pilot if the displays are attacked in piecemeal fashion. To get information about the performance of the vehicle, the pilot must read all three as well as the tilt meters. In order to control the vehicle, he must integrate all this information into some meaningful whole before he attempts some control action.

Since it is anticipated that the control of a space vehicle will be achieved by the use of rockets arranged about the vehicle, there will be non-continuous control of the vehicle. Current research indicates that with this kind of control, precise movement by a human operator is quite difficult. Research may be required to determine a method of integrating stepwise control so that it appears continuous or a method of obtaining continuous control of rockets through some kind of power control valve. This kind of control might necessitate a new approach to propellants.



While the ecological problems and physiological effects, including acceleration involved in space flight, are being studied, these problems related to the control and navigation of the space vehicle by a human operator have been neglected. Since requirements for the proper specifications for instrument design are so great, it would be desirable to have a continuous research project to obtain the necessary information.

This research should consider the problem of scaling the physical measurements and variables to the different methods by which the human operator can obtain information. Provision must be made for appropriate gain changing.

Consideration must be given to building computers that can be incorporated into the system with such read-out devices that the crew can achieve an optimum combination of information at any given time. Research should evolve the optimum combination. Provision must be made for automatic log keeping and read-out from this log.

This undertaking should provide the space crew with a set of displays that will minimize the problem of extracting all the information it needs. This information display should minimize control difficulties and the decisions the crew will have to make.

Without this effort, the information displays of the crew will be just "one more set of steam gauges." ★

Typical ram jet components produced by Finn Aeronautical Division.

We specialize in precision welded sheet metal components for missiles, jets and ram jets

We have the experience, the equipment, the men and the approvals to carry out your most complex experimental welding and fabrication of jet, ram jet and missile engine components.

Some of the superalloys we've worked and welded include N-155...A-286...the Nimonics...Inconel-X...Inconel-W...Hastelloy...Timken...and stainless steel. Our welding department includes certified Sciaky spot welders, USAF certified heliarc welders and complete, USAF-approved X-ray facilities.

New Air for Engineers

by Joseph G. Logan, Jr.

Cornell Aeronautical Laboratory, Inc.

IN THE PAST few years, the interest of aeronautical engineers has turned toward higher flight speeds and flight Mach numbers—up to 30,000 feet per second, about 30 times the speed of sound. In the regime between Mach numbers of six and 30, the "hypersonic" regime, the ideal gas concept of air must be abandoned. While this fact will be of principal import to the aeronautical engineer, its effects may extend even to the electronics engineer.

Air at room temperature is, of course, composed primarily of a mixture of oxygen and nitrogen molecules, about 21 per cent oxygen and 78 per cent nitrogen by volume. The remainder consists of small amounts of argon, water vapor, carbon dioxide, hydrogen, neon, krypton, and xenon. For the maximum temperatures encountered in the supersonic flight regime, engineers could regard the molecules of oxygen and nitrogen as rigid dumbbells. In this concept the molecular motions induced by collision were conflicted to translation and rotation. In the hypersonic regime the molecules of air have a much more complicated behavior (Fig. 1).

For example, the temperature behind a normal shock wave at a Mach number of six is about 1500°K (2240°F). As the temperature of the air gradually increases above this point, the molecules cease to behave as rigid dumbbells and begin to vibrate as a result of collisions. At Mach 10 flow the temperature behind a normal shock wave reaches 3000°K (4940°F) and the oxygen molecules begin to break up or dissociate. At these temperatures the molecules and atoms also begin to ionize and collisions between molecules result in the formation of nitric oxide. Similarly, at a flow Mach 17 temperatures reach about 6000°K (10,340°F) and nitrogen begins to dissociate.

The extent to which the composition of air varies with temperature is clarified in Fig. 2. It becomes apparent that, as a result of the breakdown of oxygen and nitrogen molecules at temperatures of about 6000°K, the air can contain as many as 10 different components. The introduction of these new components alters the thermodynamic properties of the air, and forces the aeronautical engineer to discard many of the rules he has lived by for so long.

Flow Phenomena Modified

Recently, calculations of the "new" thermodynamic state of the air at high temperatures, including the specific heat and the speed of sound, have been carried out at CAL. A large increase in specific heat occurs as a result of the new ways in which energy can be distributed in air at high temperatures (Fig. 3). The chart reveals that the specific heat at constant pressure can exceed the ideal gas value by factors of 12 at temperatures of 7000°K. In other words, it takes about 13 times as much energy to raise the temperature of a given mass of air one degree at 7000°K as at room temperatures. Engineers designing hypersonic shock facilities for operation in the 5500°K to 8000°K temperature range find this a real problem.

Another phenomenon observed is the decrease in the molecular weight of air as a result of the increase in the number of particles at high temperatures. The equation of state must therefore be modified to include the molecular weight as a parameter. Normal shock calculations must also be modified to reflect the altered relations between pressure, temperature and density. Accurate knowledge of the state of the air behind shock waves thus becomes indispensable to the engineer making aerodynamic flight calculations.

Effects of Real Gas Behavior

The changes in those properties of air referred to as real gas effects may considerably alter the equilibrium phenomena in the flow field outside the boundary layer. The first marked effect of the real gas behavior on aerodynamic phenomena is observed in the temperature obtained behind normal shock waves, as, for example, at the stagnation point on a blunt body. Since the amount of energy required to increase the temperature of air depends on the number of ways in which the energy can be distributed among the air components, the introduction of any new degree of freedom requires that more energy be supplied in order to achieve a given temperature rise.

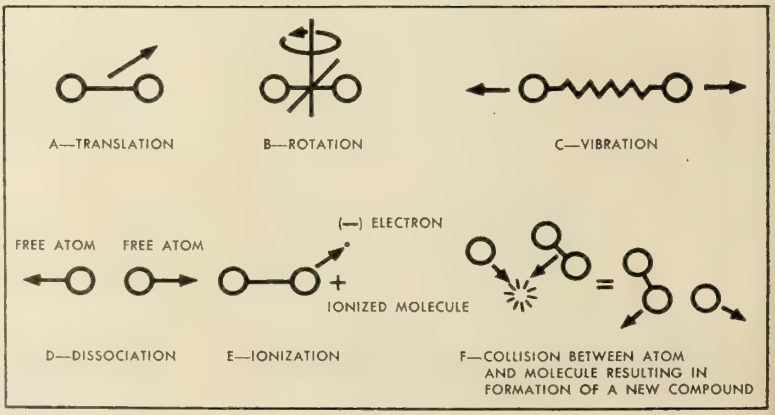

Fig. 1. The molecules of air in the hypersonic regime have a more complicated behavior.

"Swifter than arrow from the Tartar's bow"

. . . wings the modern-day research rocket on its mercurial mission. Plunging through the heavy atmosphere at supersonic speeds, the Grand Central Rocket Co. ARROW is demonstrating amazing versatility and reliability in all phases of ultra-high speed research.

Grand Central provided the multiple ARROW rocket power-plant for the two-stage HTV (Hypersonic Test Vehicle) developed by Aerophysics Development Corporation for the United States Air Force.

Grand Central ARROWS are also playing a prominent role in the final two stages of the United States Air Force's "Operation Farside" now being developed by Aeronutronic Systems, Inc., a subsidiary of the Ford Motor Co.

Resistance winding, supported on ceramic-insulated posts or on card, is in direct contact with environment to be measured, and can have time constants as fast as 50 milliseconds. Full-scale output voltages of 5 volts can be delivered directly to telemetry commutation circuits. Units operate over selected ranges from −320F to +750F (−200C to +400C), with accuracy better than ±1% of full scale and repeatability of ±0.2%. Calibration Certificate giving precise 5-point calibration supplied with each unit. Stainless steel case and rugged construction withstand 1500 psia pressures, ±25 g vibration, and 60 g shocks under MIL-E-5272A. Send for Technical Bulletins 1182 and 1350.

TRANS-SONICS
INCORPORATED
BURLINGTON, MASSACHUSETTS

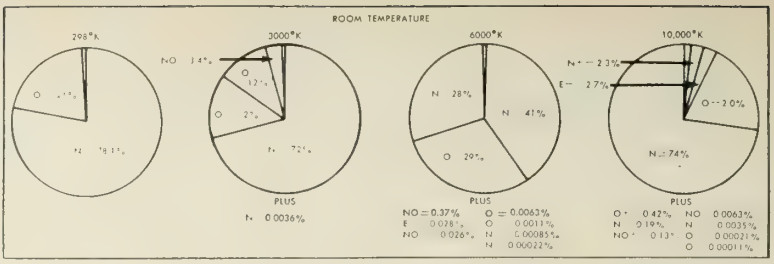

Fig. 2. Composition of high-temperature air (Density = one atmosphere).

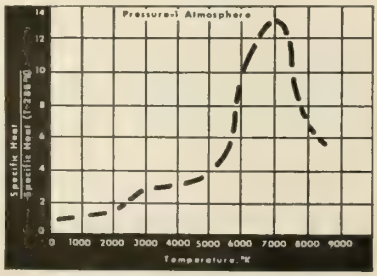
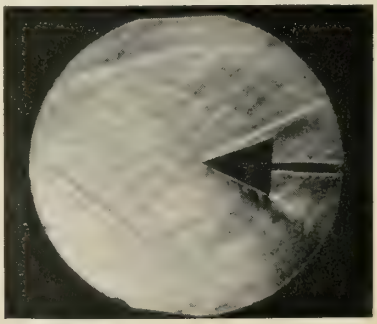
Conversely, if there is a large number of ways in which the energy can be distributed, the gas temperature that can be obtained for a fixed amount of energy is always less in the real gas than in the ideal gas.

Consequently, the actual stagnation temperatures achieved behind normal shock waves is much lower than the temperature which would be calculated assuming that the air behaves as an ideal gas with a specific heat ratio of 1.4. The results shown are based on the assumption that thermodynamic equilibrium is achieved behind the normal shock waves; that is, that sufficient collisions have occurred so that subsequent collisions do not alter the thermodynamic state.

Another important difference between high temperature and low temperature flows at a given Mach number is in the shock angle on a wedge (Fig. 4). This is important because measurements of attached shock angles are commonly employed in determining Mach numbers in wind tunnels. At a given Mach number large differences in shock angle can result from the thermodynamic changes occurring in high temperature air. The difference is most striking for the wedge angle for which the oblique shock just detaches from a wedge. For real gas flows at high temperatures the oblique shock wave can remain attached for much greater wedge angles.



Lift and Drag Complications



In two-dimensional steady flow expansions (known as Prandtl-Meyer flow), the actual flow Mach number increase across an expansion zone is smaller than would be calculated assuming ideal gas behavior. Fig. 5 shows that for supersonic flow expanding around a 20 degree corner the expansion zone is thinner, and the final Mach number is smaller than those obtained assuming ideal gas conditions. Since the pressure distribution over aerodynamic bodies is related to the flow Mach number, it can be expected that calculation based on ideal gas flow for pressure distributions over bodies will be inaccurate in high temperature flow fields.

As a final typical example, consider the effect of the real gas on the design of hypersonic test facilities. In the design of nozzles to obtain high flow Mach numbers, the nozzle ratio required in a real gas is much greater than the one calculated assuming an ideal gas.

The interpretation of data obtained in such facilities also is largely dependent on accurate calculation of tunnel flow conditions, since, as yet, the problem of measurement of temperatures and pressures in short-duration, high-temperature, low-density flows has not been entirely solved. However, before data obtained in these facilities can be reliably applied to full-scale bodies, it is necessary to learn much more about the air and its properties. One of the important problems being investigated at CAL deals with the actual state of the air in hypersonic shock tunnels. It has been assumed up to this point that the air in the high-

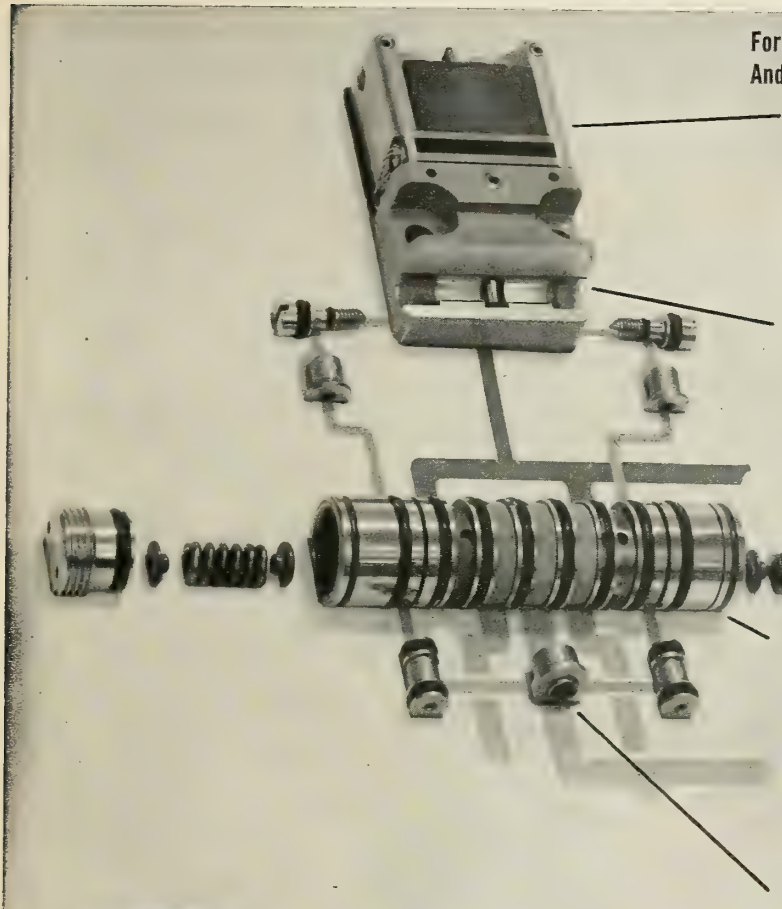


Fig. 3. (Below). Fig. 4. (Right).

New Low Hysteresis and Threshold in *HYDRAULIC RESEARCH'S*

DRY COIL SERVO VALVE

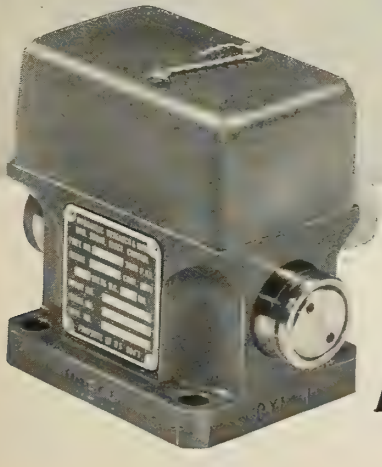
For High Performance Stabilization And Control Systems

DRY COIL TORQUE MOTOR

Unique isolation diaphragm in the Hydraulic Research Servo Valve acts as a fluid barrier to keep coil and motor completely dry. Build up of magnetic particles in the flux gap is eliminated. No magnetic filters are required. Because torque motor operates in air there is no coil deterioration due to immersion. Pressurized electrical connectors not required.

SYMMETRICAL HYDRAULIC AMPLIFIER DESIGN

Torque motor and nozzles are arranged about the center line of torque arm to minimize null shift. Motor mounting points are symmetrical about same center line to further improve stability in varying ambient and oil temperatures.



UNITIZED POWER STAGE CONTROL ASSEMBLY

Power sleeve houses control spool, centering springs and null adjustments. All are stainless steel. Adjusting mechanism is not subject to different coefficients of expansion, providing excellent null stability with temperature changes.

Near perfect alignment gained by this type of construction lowers threshold. Micro finishes keep friction to minimum reducing hysteresis and increasing valve life.

TRIPLE FILTRATION

All oil that passes through hydraulic amplifier section is filtered three times. The Hydraulic Research Servo Valve has five internal micronic filters of corrosion resistant steel to assure trouble-free performance and improved reliability.

The Hydraulic Research Dry Coil Servo Valve is available in quantity for high performance flight and control systems. ***Write for additional engineering information.***

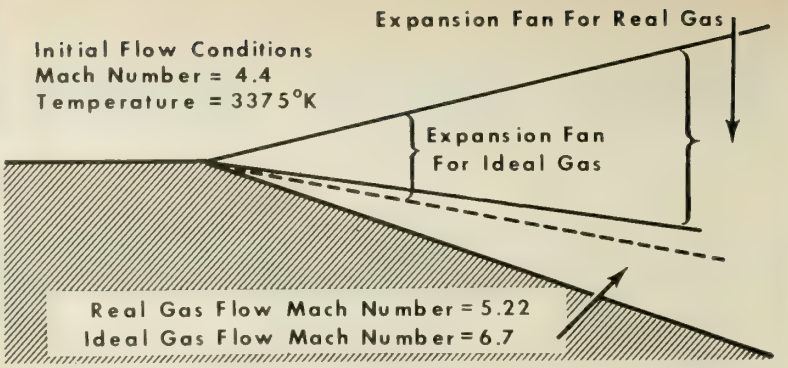

Fig. 5. Supersonic flow expanding around a 20 degree corner.

temperature region has attained the aforementioned state of thermodynamic equilibrium. Each of the forms of excitation shown in Fig. 1—translation, rotation, vibration, etc.—requires a certain number of collisions between air particles in order to reach the equilibrium state. A finite time, known as the characteristic relaxation time, is therefore required for equilibrium to be achieved.

Hypersonic nozzles must be designed so that temperature changes do not occur so rapidly that the thermodynamic state lacks sufficient time to adjust to the altered temperature conditions. Knowledge of the relaxations for the different processes are being carried out at CAL and other laboratories. Initial studies have indicated that it may be necessary to consider the relaxation time in the design of nozzles so as to insure that thermodynamic equilibrium is maintained in regions of rapid expansion.

More Answers Needed

Interest in the problems introduced by the high temperature phenomena has triggered many new fields of research. As an example, this interest has led to studies of the kinetics of nitric oxide formation and has stimulated the development of a special shock tube for the study of chemical reactions at high temperatures.

Only a few of the many new problems introduced by the high temperature air phenomena have been discussed here. There are many others—for instance, the heating produced by radiation behind a shock wave may have important effects at high flight Mach numbers. Such problems are now being investigated in special shock tube facilities at CAL. There is also a sufficient number of free electrons present in air at temperatures above 3000°K (or above a Mach number of 10) so that the conductivity of the air is high. This high conductivity may pose serious communication problems. Further, it is to be expected that the real gas effects may modify the boundary layer and heat transfer phenomena. For example, above 3000°K the air contains many dissociated particles and if these particles diffuse across the streamlines and recombine at the wall, the surface heating may be increased above that obtained without diffusion.

Consequently, aeronautical engineers are on the threshold of designing aircraft and missiles to fly through an entirely different medium—a medium whose ramifications are just beginning to be recognized and whose characteristics have been only sketchily explored. We call this medium a new air for engineers.★

Extra Muscle for Missiles

A DEPENDABLE SOURCE OF AUXILIARY POWER

Pioneers in the development of reliable, lightweight, self-contained monofuel auxiliary power systems for guided missiles and piloted high performance aircraft, Kidde now offers its combined engineering talents and precision manufacturing resources to firms interested in advanced applications of auxiliary power systems.

At present, Kidde has available turbine-driven units with horsepower of up to 200. These high speed units are designed to supply accurately regulated power at mean altitudes of 40,000 feet and up. However, they may easily be made environment-free, permitting airframe builders extremely wide latitude in systems design.

As a part of its power system development program, Kidde has gained wide experience with many monopropellants. These include ethylene oxide, hydrazine, hydrogen peroxide and propyl nitrate.

Whatever your present or future auxiliary power requirements, Kidde is ready to develop, test and manufacture equipment which will meet your exact specifications. For full information, write Kidde today.

Where Miles are Measured in Thousandths of an Inch

As ballistic missiles go farther and faster, weight becomes an increasingly critical problem. Walls of rocket cases, for example, must be still stronger to withstand higher pressures, yet still thinner to cut "hardware" poundage to a minimum.

Obtaining optimum wall thinness throughout in rockets now being developed is one of M. W. Kellogg's current defense assignments. It is a complex engineering task and demands a highly specialized knowledge of metallurgy, metal fatigue, heat transfer, corrosion, weight-strength relationships, and welding techniques.

The M. W. Kellogg Company has been closely associated with the development and fabrication of rocket cases and components since 1947. Inquiries are invited from organizations wishing to put Kellogg's specialized background to work on specific problems.

Human Engineering for Space Vehicles

New field of engineering for astronautics era

By Cmdr. George W. Hoover
Office of Naval Research

IN THE PAST human engineering has played the role of patcher-upper and ex-post-facto adviser—an aeronautical Mr. Anthony. Today it is playing a very definite part in the design of modern aircraft and spacecraft. Component manufacturers as well as airframe builders are retaining human engineers on their staff or in a consultant capacity. The human element is at last being taken into account in machine design.

Tomorrow, with the coming of the spaceship the human engineer must move up to take his place in the design team, because space flight cannot be achieved unless maximum integration is effected between man and machine. Effecting this integration is the human engineer's job.

Human engineering, however, cannot play its part in achieving space flight unless it is fully accepted by all members of the design team. Some engineers have refused to recognize this new field and in some cases have been well justified. Like every new science, human engineering has had and is still having "growing pains."

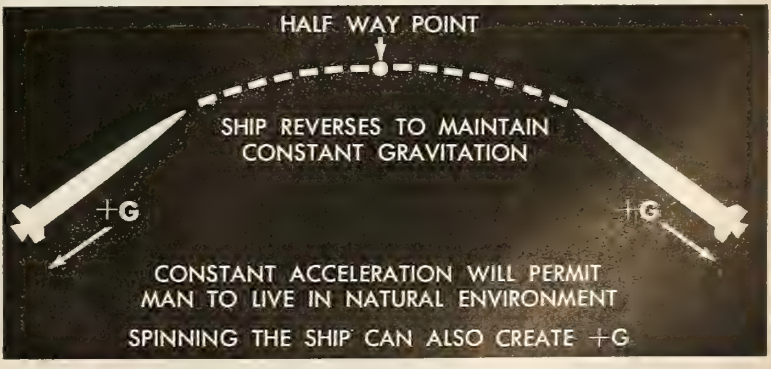
Common Language Needed

Perhaps the most important reason for this nonacceptance is due to a language problem. Most human engineers are psychologists by training and have had to draw from the vocabulary of that field to create new terminology to communicate the results of their findings. This was necessary because they were working in new areas where such things as "JND" (just noticeable difference) and "learning curve" (the rate of operational improvement in a given task) had no equivalent in engineering vocabulary.

This, however, certainly follows the pattern of other fields—the continuous misunderstanding between engineers and physicists, electrical engineers and electronic engineers, and even physicists and nuclear physicists. There is always a period when the language of a new art or science is being rephrased in terms of an old one.

But in the space flight problem, the language required is new to all engineers, physicists and human engineers alike, and so the members of the team must seek a common language in order to be able to interpret their mutual problems.

In the design of aircraft, until very recently, engineers as a rule could expect the pilot to meet the control requirements generated by the machine. At the present time these same engineers are facing much more complicated problems because the machine is forcing the pilot to extend his capabilities to the limit.



High altitude has forced the pilot to use oxygen equipment and pressure suits. High performance has brought about the need for anti-g suits. All of these require considerable training and demand that pilots be in extremely good physical condition. In the design of the spaceship the engineer will be forced to invite the aid of the human engineer because the machine's capabilities, by its very nature, will be far beyond the pilot's capability or physical limitation.

The spaceship will call for protection against extreme g loadings on the pilot due to the high thrusts which the ship may have to utilize. It will be necessary to protect against zero outside pressure in the event of loss of cabin pressure.

Because of the altitude the pilot must also be protected from cosmic and ultraviolet radiation, meteorite hits, intermittent weightlessness, and many other conditions abnormal to his ordinary pattern of living, all requiring definite procedures with no allowance for error. In space flight, just as in a submarine, there can be no mistakes, —but even more so, because the return to earth of a spaceship is more complicated than the return to the surface of the ocean by a submarine.

Man-Machine Interdependence

In space flight there must be as complete reliability as possible of both

Constant acceleration of vehicle eliminates problem of weightlessness in space.

man and machine. Both will be taxed to extreme limits.

If the spaceship is to operate successfully it cannot be designed by past conventional methods. Such methods might entail compromises of the total system which put an increased burden on either the man or the machine; and from past experience such burdens will undoubtedly be placed on the man.

In order to avoid any such compromise, the spaceship cannot be designed until a complete analysis of the problem is made and answers are found to such questions as these: What will man need to orient himself in space? How does man operate most efficiently under positive and negative g? What does man need to protect himself against extreme temperatures? Complete understanding is required of how man functions most effectively. Such an analysis can only be achieved by the joint efforts of engineers, physicists, human engineers and physiologists working as a team.

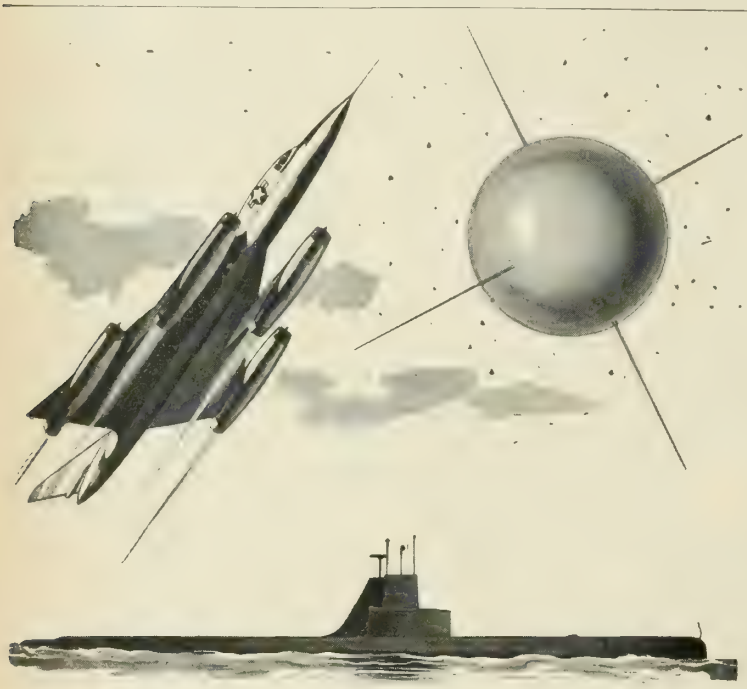
Human engineering is much more fundamental than experimental psychology and requires a thorough understanding of the way in which a man functions in order to determine his requirements when operating with a machine in a closed loop. Here the human engineer cannot accept what appears to be a reasonable answer, but must determine precisely what the man needs to operate efficiently and relay these requirements to the engineer.

Predesign Planning Vital

Generally, human engineers have been called into the design problem after the equipment has been designed and found to need improvement. They should be active in the establishment of the design requirements in order to insure compatability with the functions of the operator.

For example, the development of the space suit should have utilized the first signs of its need became apparent. services of human engineers when the Instead of this, the engineers were forced to design a suit to meet only the immediate problem with only partially adequate results.

The real task was to define the problem of how to create a proper environment to meet all conditions—not to attempt to solve it by designing a suit. A suit is only *one* way to create an environment, but unfortunately it does not meet total requirements, one of which is comfort.



Problems of space flight must be approached properly in order that mistakes which may prove fatal will not be made. Human engineers must be brought into the team at the beginning in order to insure that equipment will be designed to meet the crew's requirements.

Take the problem of weightlessness. A great deal has been written on this subject and many schemes have been devised to study means by which it would be possible for man to live in this environment. Many writers have pointed out the problems involved—eating and drinking, sleeping, working. They have pointed out the necessity for physiological as well as psychological studies to determine what will be required in the way of equipment and training for crews of spaceships.

Weightlessness comes about when the ship stops accelerating and coasts, or during extreme changes in thrust. There is no requirement for zero acceleration other than that based on present day rocket capability which, by no stretch of the imagination, will be sufficient to permit manned space flight.

Man's requirements necessitate his living in a gravity system. This calls for a vehicle which will be in a constant state of acceleration or deceleration, not one which will force man to live in an environment to which he is unaccustomed. The only problem will be during changes in amount or direction of thrust.

Is it better to accept a system

We may have already solved your flexible ducting problem

Flexible's been solving tough ducting problems in many different fields for a great many years. And has engineered all kinds of special shapes and tubings in a wide variety of fabrics and coatings for unusual applications . . . a starter duct for jet aircraft, for example, as well as special ductings used in the missile field for ground support. So it could be that we already have the answer to your particular problem. If not, we'll put our research facilities, including our brand-new laboratory, to work immediately. If silicone ducting is called for, our special Silicone Department, working with automated machinery, is prepared to meet your specifications.

To find out how Flexible can solve your ducting problems, write us, outlining your requirements. Our engineers will be glad to put their experience to work for you. Write to Dept. 21N.

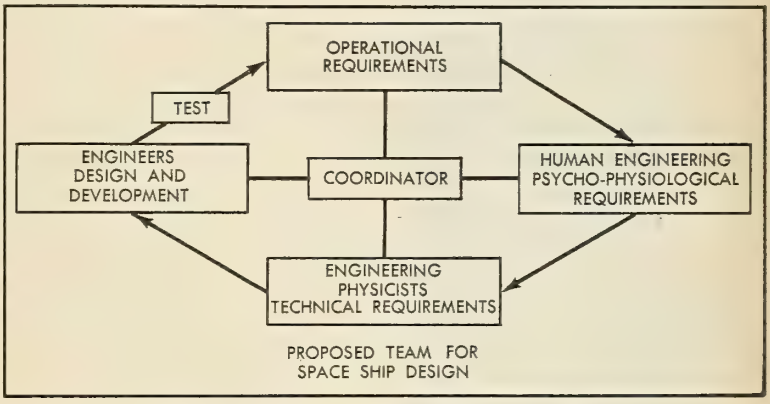
which creates an entire family of new problems, or to design a system which eliminates the problem? A man cannot be changed—the system can be.



Engineers will state that even by extrapolating the state of the art to some future time, there is no foreseen propulsion method which can give constant acceleration during space flight. This will have to be found. Just as important as the requirement for temperature-resistant material for re-entry, just as important as the need for maximum thrust, is the fact that man cannot change his way of living. This is a man-machine system and the man is just as important as the machine.

Human engineering must be used and emphasized if manned space flight is to become a reality. With human engineering the focus changes—from how much radiation a man can take, to how protect him against any radiation; from how much sudden acceleration he can take, to how to propel the ship within the pilot's normal limits; from how much temperature a man can stand, to how to maintain a tolerable temperature.

Up to now pilots and crews have had to be given special training and equipment and have had to adjust themselves to the deficiencies of inadequate machine design. In the spaceship this is not acceptable.

"Family tree" of human engineering springs from many scientific fields.

Organizational chart shows the interdependence of all phases of design problems.

Space flight is not something mysterious or impossible. It is just another advanced step requiring an efficient man-machine system. It must be faced squarely, and this can only be done with human engineers working as a team with the design engineers.★

Opinions are those of the author. They do not necessarily reflect the views of the Navy Department.

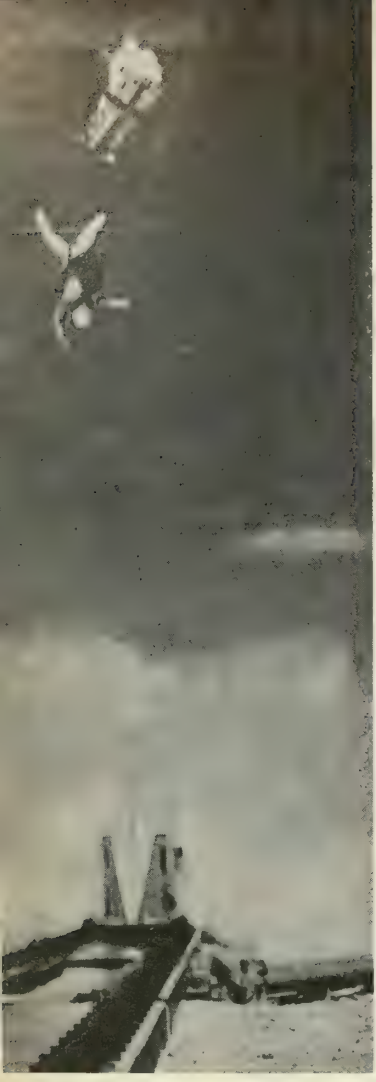
CUSTOM EXTRUSIONS
ROLL-FORMED SHAPES
AND SECONDARY OPERATIONS

WERNER Aluminum plays a vital role in the production efficiency and sales success of such industries as: aircraft—appliances—curtain walls—electrical fixtures—furniture—railway coaches—storm doors and windows—sliding door hardware—trailers—trucks—buses—TV antenna tubing and masts.

WERNER extrusion and roll-forming services cover all alloys including the High Duty alloys, RR57, RR58 and RR257.

WERNER equipment includes heat-treating and fabricating facilities as well as other secondary operations such as punching, drilling, riveting, cutting, bending, welding. Every manufacturing phase from coil or billet to finished part can be performed in our own plant.

WERNER quality controls guarantee exact conformance to critical dimension requirements and design specifications.



WERNER experience, skill and versatility assure prompt delivery to meet production schedules.

Get facts and data on what aluminum can do for you. Send for this free booklet— **"New Horizons In Aluminum."**

Rocket Sled Experiments

By Alfred Zaehringer

ROCKET SLED testing has become a vital part of our missile programs. Aerodynamics, propulsion, structures and even human factors are being evaluated in this economical, captive and recoverable method. There are now five major rocket tracks in the United States and four smaller facilities. The big tracks and lengths are:

1) SNORT, China Lake, 21,500 ft.
2) Baker 4, China Lake, 14,000 ft.
3) Edwards AFB, 10,000 ft., expansion to 20,000 ft.
4) Holloman AFB, expansion to 35,000 ft.
5) SMART, Hurricane Mesa, Utah, 12,000 ft.

Smaller tracks are located at Eglin AFB; Aberdeen Proving Ground, Aberdeen, Md.; Naval Proving Ground, Dahlgren, Va.; and Redstone Arsenal, Huntsville, Ala.

Tracks Busy

There is a great backlog of work stacked up for every track. Speed records for these tracks have constantly edged up to keep up with the ever increasing speed of aircraft and missiles. The Coleman track, for example, qualifies at Mach 2 (1500 mph at track elevations) but recently SMART had an 1800-mph run. This high-speed SMART run was made with a 9400-pound vehicle which went off the track, over the end of the 1500-foot high Hurricane Mesa, and some one and a half miles into the valley below.

The highest speed attained to date is believed to be the 2180 mph attained by SNORT on a single rail sled with recovery at the end of the run. In a two rail run on SNORT, 1705 mph was attained. Holloman engineers believe that when their 35,000-foot track is completed, it may have Mach 4 capabilities for aircraft and missile testing. Edwards will have its 20,000-foot track finished in about a year. It is designed for Mach 4.

Grading on the Edwards site has been completed and digging and pouring the concrete foundation should start soon. The distinguishing feature

Left—Hurricane Sam flails wildly during an ejection sequence. Sled has just entered water brake and is about to hit arresting gear. Below—Aerial view of SMART facility at Hurricane Mesa, Utah. Breech end is at top. Test specimen hurtles over 1,500 ft. cliff at lower left. Track is 12,000 ft. long.

of the Coleman track, the 1500-foot cliff at the "muzzle" end, will keep SMART in the business of testing human escape techniques, essential in high-speed jet and rocket aircraft.

Survival Tests

The escape problem for high-speed aircraft still remains critical. Above supersonic speeds, only 20 per cent of the pilots can expect to survive during an emergency ejection. With increasing speeds and altitudes, the trend appears to be heading toward pods or capsules which will insure safety at ultra-altitude operations. Capsules eliminate the effect of air blast and also obviate the need for special suits and survival gear.

An ever increasing track function, on the other hand, is to test nose cones of ballistic missiles. It has been said that the major function of the longer tracks is to simulate heating problems of full-scale, nuclear warheads for the IRBM and ICBM.

Hot Slippers

One of the major problems associated with the present slipper-type sleds is friction. These shoes have to clamp over the rails to keep the vehicle captive at all times. Since vehicle weights are not very high and since the fast speeds mean only transient contact, present rails suffer only small wear at speeds of 500 to 600 mph. However, vehicle weights have been going up: full-sized escape systems, then entire cockpit sections.

Missile nose cones and warheads have also grown. Therefore, hot slippers are becoming a problem. Stainless steel has been successful here but increasing attention is being paid to the ceramics, ceramets and ceramals. There is also the hydrodynamic approach, which would eliminate any solid contact surfaces.

Solid versus Liquid

The old question of rocket propulsion systems—solid versus liquid—again cropped up. It was agreed that for sled propulsion the following conditions have to be satisfied: (1) performance, (2) economy, and (3) reliability. At present, solids are widely used because of their high utility. Solid motors often give the highest thrust per given cross-sectional area. This is especially important in track work, and therefore solid motors have become workhorses at most tracks. Everybody, too, is likely to agree that solids are much more reliable than liquids. However, economy, especially for high thrusts and repeated operations at these high thrusts, may dictate going to liquids.

It would be more economical, for example, to couple 10 18,000-pound solid RATO motors for a few runs than to develop an 180,000-pound-thrust liquid motor (or two 90,000-pound engines). But, if you have a hundred or a thousand tests at 180,000 pounds, it may pay to develop a liquid engine. The Coleman track, because of its remote site, has heretofore operated exclusively on solids, but has just taken delivery on two Aerojet acid engines of about 50,000-pounds thrust.

As one track man put it, solid motors make nice modular units and allow great flexibility in arriving at almost any thrust level. Too, solid motors, having been loaded at the factory, are time and personnel savers, letting the track concentrate on the testing.

The SMART track has used six different solid units with great success. Coleman has a stockpile of now-obsolete *Loki* rockets for smaller vehicles. HVARs have also been used. Two of the most commonly used units are the 2.2KS-11,000 and 5KS-4500 RATOs. Two of the larger units are the T-50 booster and the 224-B made by Hercules Powder Co. ★

PRESSURIZATION!!!

Now get the facts on Kahn's versatile new Portable Air Stand. This dependable, portable equipment provides HIGH PRESSURE – dry air or nitrogen for pressurizing aircraft or missile systems.

- 4-Stage Compressor delivers 15 SCFM of dry air at pressures to 5000 PSIG.
- Kahn's High Pressure Automatic Dryer provides dryness of minus 65 degrees F. or lower dew point.

KAHN'S HIGH PRESSURE PNEUMATIC ACCESSORIES TEST STAND

Highly versatile 3-Station Component Test Stand delivers 5000 psi. air at minus 65 degrees F. dew point. Tests components such as Pressure Switches, Solenoids, Cylinders etc. KAHN'S INTERLOCK SAFETY feature prevents component tampering under pressure.

Inquiries Invited.

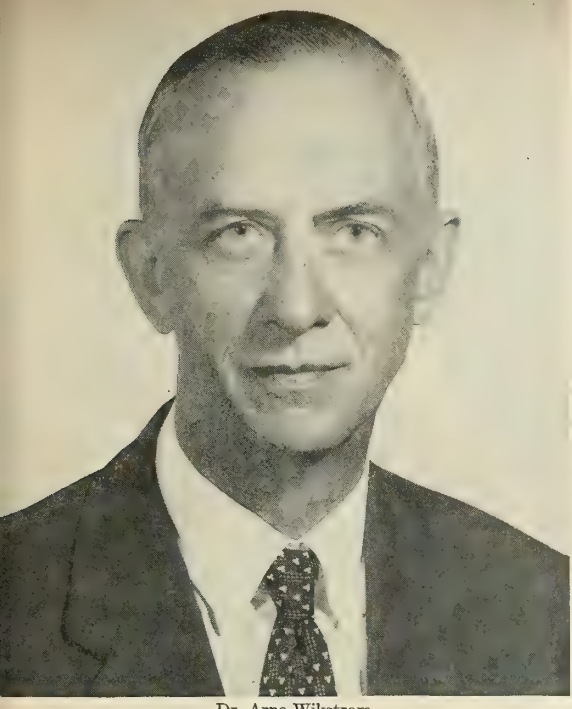
Propulsion Engineering

By Alfred J. Zaehringer

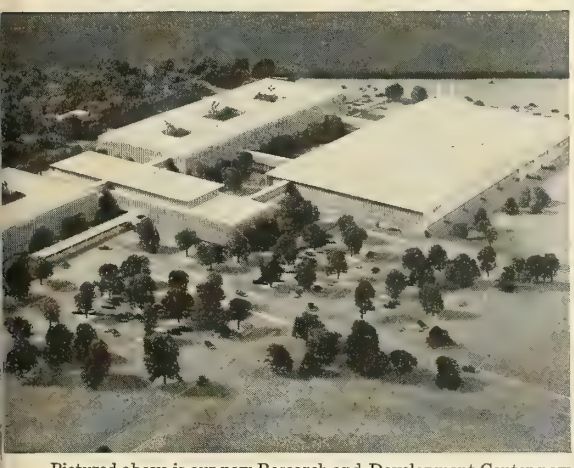
ROCKETS VERSUS BALLOONS. Performance of both vehicles is surprisingly similar, according to High Altitude Test Division at Holloman. The balloon has lifted 1300 pounds 76,000 feet high (98.7×10^6 ft/lb) while an *Aerobee* has lifted 154 pounds some 119 miles (97.0×10^6 ft/lb).

BURNING RATE OF NITRIC ACID PROPELLANTS has been studied at USNOTS, China Lake, Calif. With 2-nitropropane and 90-100% HNO_3, small changes in acid concentration (near 100%) cause large changes in consumption. This "low pressure step" is said to be related to the surface temperature of the burning liquid. Turbulent combustion is related to acid concentration and the number of carbon atoms in the fuel.



NEW PERCHLORATE. Nitrosyl perchlorate, $NOClO_4$, has been found to be quite stable in the anhydrous state. However, research in progress at the University of Amsterdam shows that the compound can be exploded by ultraviolet radiation.

BORON FUEL RESUMÉ. After 11 years of research, NACA finds that general combustion performance of the hydrides is good. Handling and storage are problems but not impossible to solve. Big problem is the formation of boric oxide on combustion. At 1000-2000°F B_2O_3 is a solid, but in the 2000-4000°F range it is a messy, syrupy liquid that clogs up hardware. This crudding is especially bad in turbojets, which may restrict it to special engines or to afterburners. However, NACA has successfully flown a pentaborane-powered ramjet. On the other hand, the Lewis Lab is disappointed in its results with metallic boron-jet fuel slurries: high combustion efficiencies could not be achieved at high-altitude conditions.



HOKO CONCENTRATED NITRIC ACID PROCESS is now being introduced to the United States. The Pintsch-Bamag process produces the 98-99% pure acid directly and can also produce nitrogen tetroxide, nitric oxide, RFNA or any concentration of nitric acid. Raw materials for 100 tons/day of 98-99% acid are 29 tons of anhydrous ammonia and 17 tons of oxygen.

LITHIUM DEUTERIDE may be under study as a fusion rocket propellant. Small amounts fed into a combustion temperature heated to 4000-7000°F would generate large amounts of heat which could be used to expand the helium gas exhaust product. Nine grams of LiD would liberate 4.3×10^{20} ergs. However, two of the big problems are diluting the stream to keep down temperatures and yet maintaining a self-sustaining reaction and adjustment of the proper feed rate.

METALS FOR ROCKETS. Satisfactory oxidation resistance for molybdenum still hasn't been attained. Tungsten might provide another 300-500°F increase but its oxidation resistance is also poor. Columbium may, however, provide another temperature increase.

Dr. Arne Wikstrom

Pictured above is our new Research and Development Center now under construction in Wilmington, Massachusetts. Scheduled for completion in early 1958, this ultramodern laboratory will house the scientific and technical staff of the Avco Research and Advanced Development Division.

A SCIENTIST-ENGINEER SPEAKS ABOUT AVCO

MORE AND MORE it is being appreciated that no sharp borderline between science and engineering should exist. These two fields must strongly overlap to bring into being the fullest creativity of both.

To span the gap between science and engineering is one of the *big* problems—it is one which no laboratory can ignore. In this no-man's-land there are engineers who are physicists and physicists who are engineers. Avco is encouraging a staff of such men, men who are highly trained in the sciences but who realize that the ultimate goal is to apply this knowledge in ways that will enable mankind to live better in a better world of tomorrow.

Industrial research must rest on the foundation provided by the creative basic scientist. Yet its end product—new commercial items, new defense systems and new techniques—comes into being only through the insight and skill of the creative engineer.

Avco's newest division has a climate of creativity, coupled with long-range corporate goals. In this atmosphere creative and far-sighted professional men, whether scientist, engineer or any one of the infinite number of combinations thereof, will find rewarding work at the Research and Advanced Development Division of Avco.

A. Wikstrom

Dr. Arne Wikstrom
Special Technical Assistant to the President

Avco's new research division now offers unusual and exciting career opportunities for exceptionally qualified and forward-looking scientists and engineers in such fields as:

Science:
Aerodynamics • Electronics • Mathematics • Metallurgy
Physical Chemistry • Physics • Thermodynamics

Engineering:
Aeronautical • Applied Mechanics • Chemical • Electrical
Heat Transfer • Mechanical • Reliability • Flight Test

Ultimate Weapon: The Mind of Man

By Tom Wilcox

Air Force Office of Scientific Research

THE SIZE, force and shock action of a military machine are formless, useless capabilities without the supreme motivation, guidance and intuitive genius of the mind of man. In the military affairs of our nation, as in all other endeavor, the study of science alone—without a clear understanding of the implications of its findings—can result in the enervation of man's progress. The finding of a principle or a thing is no more important than the recognition of its implications.

The Air Force Office of Scientific Research, Air Research and Development Command, provides a mechanism for daily translation of this philosophy from words into action. Scanning constantly all areas of industrial and scientific research, it seeks, finds and supports investigations which help to keep the Air Force in a position of technical and strategic superiority.

It has been said that the Air Force scientist is working the aviator out of a job; that research and development effort leads inevitably to only two possible conclusions: the removal of man from the aircraft and the development of the ultimate in destruction.

The first of these statements is neither inevitable nor desirable; the second is only partially correct. If it were true that science is taking the pilot out of the combat picture, we should view this as tragic and dangerous.

For science to serve the ultimate ends of the military mission, it must insure that the mind of man will, in some way, influence and control every weapon system we create.

To subordinate the intellect of a military commander to a synthetic complex of electronic gadgetry would be to deprive that commander of the imaginative and intuitive genius which has always led to victory in battle. Engineers and technicians can produce many types of computers which will rapidly calculate the most complex mathematical problems. They can provide them in many shapes and sizes. They can place them on the ground or fly them. With them, we can control speeds and altitudes. We can use them to navigate and to drop bombs or fire missiles and bullets.

But computers are unemotional. They cannot think. They do not reason. They need no food, or any stimulus other than the power which feeds their circuitry. They cannot be motivated to performance beyond that which has been punched into them, nor can they be trained to take advantage of an unforeseen circumstance or to change course in the light of unpredictable conditions. In short, they are nothing more than morons—and *wars are not won by morons.*

The history of warfare has been compared to a balance. The evolution, development and employment of new weapons tip the scale forcibly toward the side which has evolved the new concept. However, each new measure stimulates countermeasures which, if effective, balance the scale. To weight the balance to his own advantage the commander must do two things: first, he must employ his forces so imaginatively that, despite the equality and strength of his force and that of the counterforce, the imaginative commander quickly and successfully achieves his objective while the countermeasures result only in striking at phantoms.

The second factor for successful command is the ability to recognize and use the full capability of one's own resources. The creation of imaginative concepts of warfare and the recognition of our full capability are the mission of the Air Force Office of Scientific Research, and its unique contribution to the United States Air Force. Weapons which we are evolving today came from recognition of scientific discoveries of the more or less recent past.

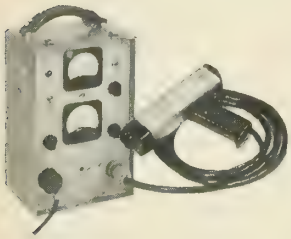
Recognition of decades of exploratory research by inspired mathematicians and physicists led to our World War II Manhattan Project. This gave us the first use of atomic energy in war and, in turn, our present nuclear fission weapon systems and industry.

Germany's work on the V-2 rocket stemmed from military recognition of the early exploratory efforts of a small group of pioneer rocket experts.

The Air Force Office of Scientific Research role in support of basic research is unique. The Air Research and Development Command has 12 major activities concerned with developing and testing weapon systems and supporting research aimed at solving the problems of weapon development.

AFOSR builds no missiles, no rockets, no aircraft. Its program is concerned entirely with sponsoring the most basic exploratory work. The AFOSR program is designed to serve as a focal point within the Command for contact with university and industrial scientific research groups in all parts of the free world.

By communication and support of these scientists, AFOSR encourages them to bring to its attention entirely new concepts and capabilities. Some of these new concepts will eventually result in forming a basis for the development of new weapon systems and concepts for their employment.



AFOSR does no actual laboratory work within its own organization. It serves as a vantage point for scanning all scientific areas and supports by contractual means those which offer the greatest promise.

Some of its programs might seem far removed from military application. For example, AFOSR might investigate the magic substance chlorophyl, the chemical which, by photosynthesis, converts the carbon dioxide in the atmosphere to life-giving oxygen. This may have important future military application.

A future spaceship may depend on a closed environment to sustain life. With present techniques we would have to carry large quantities of oxygen and equipment in order to breathe. The quantities required, of course, would be governed by the time we kept the craft aloft. So it becomes obvious that an ability to regenerate our enclosed atmosphere would have a direct bearing on range and altitude. In aerial warfare these are essential factors of tactics and strategy and may actually determine whether we will be victorious or vanquished in some future war.

The Air Force search for scientific implications might be likened to a ground-force commander's study of terrain seeking to find the vantage points of high ground and maneuver area. AFOSR and its mechanism rep-

HALOGEN LEAK DETECTOR

resent the Air Force's search for the high ground and maneuver areas in science. We must have this capability. Our potential enemy has it and backs it with resources far more extensively than we do.

Certain fields of investigation receive financial support which is no more than that required to buy two or three ordinary military trucks. The results of any one of these programs may save us millions in lives and dollars.

Research and development in the basic technical fields are among the most important investments being made to insure a safe, bright and prosperous future.

We cannot insure this future unless our support is sufficient for the task at hand—the job of searching, recognizing and supporting all scientific areas of military interest.

The need for resources is high. To exploit all areas properly, the support of exploratory research must be augmented.

A current need is for leaders of the financial and industrial world to join forces with the military in a strong partnership for support of scientific research aimed at providing the strongest, fastest, highest Air Force in the world.

We need to go higher and faster. There is a future requirement for a satellite or a platform in space. The pages of history are filled with the names of commanders who were beaten in battle by rocks, spears, arrows or shells hurled from heights they had considered impossible to scale. To scale the heights of science requires no less measure of courage, imagination and tenacity.

These two things we know: our fight for a dominant technological position must continue in full force; and we must not negate the judgment of man if we are to succeed.

We can send into space a platform for observation. We could instrument this platform to relay to us a great deal of information. But, no matter how fully we equipped it, we could still miss the basic ingredient of useful surveillance: the instant and meaningful interpretation of important data and the ability to initiate prompt action of a command nature.

Soon after man started to use the airplane as a combat observation post, someone tried to shoot it down. In short order, two men were aloft and shooting at each other. Thus evolved a completely new military dimension.

We are on the point of introducing another new military dimension as important and revolutionary as aerial warfare was a generation ago. Manned space flight and observations are within the foreseeable future, and it seems clear now that there will be uses far beyond observation. It also seems clear that, if we should put a device in a predictable orbit, it would be only a matter of time before someone tried to shoot it down. The optimum weapons system still must be guided by the unpredictable and random output of a man's imagination.

If we would insure technical victory in the present race for survival, we must mobilize all the human imagination and ingenuity in our entire storehouse of science. We must apply our findings to a complex of weapon systems in a manner which insures that they are only the useful servants of a commander, not his master. We must evolve weapons which can be employed in the unpredictable pattern of the human mind, rather than the cold, set logic of a machine. In the final analysis, it is the proper combination of man and weapons that wins wars—cold or hot.

By careful recognition and employment of our scientific input, we can insure that the order of battle will be the influence which directs the weapon. We must not build ourselves an arsenal which will direct or influence the order of battle. Much of our current effort is directed to the building of missiles. They currently deserve top priority. We must have the best possible as soon as we can.

It would be dangerous, however, to think of the missile as the ultimate end of weapon development. Countermeasures to stop missiles and means of detecting them will surely follow. We must accomplish two things: we must build missiles and missile countermeasures and, at the same time, strive for new concepts which will take their place when enemy countermeasures reduce their effectiveness.

We cannot safely assume that simply placing bigger bombs on predetermined targets will insure the final victory, or that a fixed or static defense machanism can stop the forces of an imaginative enemy. Such assumptions can well lose us a war, the nation, the American way of life.

The great strength of American arms has historically been augmented by the quick, imaginative flexibility of its manpower, from general to private. In the process of scanning our world of science, and developing and employing our arms, let us always remember a brief pasage by the contemporary author, John Steinbeck: "Our species is the only creative species, and it has only one creative instrument—the individual mind and spirit of a man. ★

The views expressed in this article are the author's and do not necessarily reflect those of the U.S. Air Force.

PRODUCTION KNOW-HOW

The organization and facilities of the newly streamlined Rheem Aircraft Division are geared to produce aircraft and missile airframe assemblies in high production quantity. New and modern operational concepts are being constantly applied to the basic talents and facilities available at Rheem Aircraft Division to assure the aircraft, propulsion, and ordnance industries of an on-schedule, high quality, low cost producer. Your letter of inquiry will receive prompt attention from our Marketing Department. *Rheem has manufactured more than 10,000 major aircraft assemblies since 1951.*

McDONNELL *Aircraft Corporation*

Nutrition in Space Flight

By Dr. Carsbie C. Adams

National Research and Development Corp.

ONE OF THE BIGGEST problems of space flight is nutrition. How is the crew adequately fed over a long period with the extreme limitations of space? How is nutrition affected by pressure, zero gravity, radiation and the inevitable psychological reorientation?

Studies to date indicate that there are no serious obstacles to nutrition in space if the individual is in good health. Digestion should not be adversely affected if the ambient pressure is not so low as to produce a physical and nervous strain to the body generally.

The matter of spaceship cabin pressure raises the question as to how great a compromise can be made with sea level conditions for long-duration exposure.

There are reports that the feasibility of zero gravity has been established. This would seem to solve the major problems of orientation as related to nutrition.

Since the exact nature of cosmic rays' origin, density and composition have not been completely established, we can only speculate on certain close similarities to conventional atomic radioactivity. One is left with the supposition that a sufficiently strong cosmic flux will induce anemia and possible leukemia. The latter disease would be quite beyond the restorative powers of nutrition.

Pressure

There has been no direct evidence of a relation between nutrition and pressure except from the view of dietary results where food has apparently been consumed in normal ambient conditions and prior to flight. However, the WADC Report 55-353 reveals some potentially useful information: a high carbohydrate meal before ascent (15,000-17,000 feet) increased both altitude tolerance (by 1000 feet) and psychomoter performance (by 2000 feet).

Adult male rats on a vitamin B_1-deficient diet for two months showed a greater resistance to lowered barometric pressure (34,000 feet) which was decreased to normal in one to three hours after supplemental thiamine feeding. However, a two-to-five month subminimal-thiamine diet seems to have no effect on man's altitude tolerance.

There is a more rapid loss of alcohol from the blood at 12,500 to 16,000 feet than at ground level. The most rapid loss of body water from adult rats at 15,000 feet occurs during the first eight hours of altitude exposure.

For the first 48 hours thyroid activity of unacclimatized rats is noticeably decreased at 11,500 feet and is accompanied by a sharp drop in rectal temperature for the first 12 hours of exposure. Thiouracil (anti-thyroid substance) taken for from four to 35 days does not affect the altitude tolerance of man at 32,500 feet.

Daily three-hour exposures to a simulated 12,000-foot altitude produced no significant change in appetite, gastrointestinal absorption, adrenal cortical function, sodium and chloride balance, urine volume or ketosteroid excretion.

The respiratory rate of an experienced pilot in action is directly related to the complexity of a given task.

Cabin pressure in a spaceship may not be equivalent to that in terrestrial craft. A typical airline cabin is set for 8000 feet pressure equivalent, just below the altitude for physiological effects.

Experience may reveal that tolerable pressure drop is an inverse function of duration.

Appetite may be influenced by mood. It has been demonstrated that eight hours at 10,000 feet induces "boredom, incoordination and headache."

Elimination at tolerable pressure reductions would either be unaffected or slightly aided. The body as a whole will eventually assume the pressure of the environment and thereafter the effect of pressure on elimination one way or another is negligible or zero.

Ingestion should not be adversely affected at any pressure which the unprotected body can endure. The pressure at which water would erupt (boil) at ambient temperature would kill the body by explosive decompression.

Susceptibility to anoxia (17,000 feet for two hours) may be reduced by a high-carbohydrate diet prior to ascent. Administration of glucose did not alter the susceptibility of rats to the acute effects of anoxic anoxia (4.5-5.6 per cent O_2). Glucose ingestion 30-50 minutes before flight prolongs consciousness time with high-altitude anoxia (27,000-30,000 feet).

The ingestion of 50 grams of glucose one half hour prior to altitude (12,700-17,200 feet) ascent decreased the intensity thresholds for vision at those altitudes. This is attributed to the elevated blood sugar. Cortico-retinal function (peripheral vision) and psychomotor function (block placement) tests indicate that significant gains in altitude tolerance (15,000-17,000 feet) can be achieved by ingesting high-carbohydrate foods before and during flight. With partial inanition, there is also an increased hypoxia tolerance due to lowered oxygen requirements.

Nicotinic acid increased the minimum survival altitude for rats by 4525 feet. Vitamin C does not affect consciousness duration in man at 27,000 to 30,000 feet. Oral vitamin E increases anoxic anoxia survival time in adult rats; mitigation occurs if the diet contains more than 12 per cent fat. Vitamin E similarly affects the rabbit. Iron supplementation in rats does not increase hypoxia tolerance at 20,000 feet.

No direct connection between appetite and oxygen has been found. Any deviation from normal sea level oxygen content in space would tend to be in the direction of hypoxia. Use of 100 per cent oxygen, except in case of emergency, would be an extravagance. The reduction of body temperature, associated with hypoxia, may demand or create the imaginary requirement for additional food, disregarding the influence of the lesser exertions of free-fall, if present. It may be expected that a modeate hypoxia of sufficient duration could be psychologically depressing and would adversely affect the appetite.

No connection between oxygen content of the cabin breathing mixture and the processes of ingestion, digestion, and elimination have been encountered in current literature.

Zero Gravity

Work is now in progress on the relationship between nutrition and zero gravity. One aviation magazine confirmed that "experiments related to the

space travel regime have established the feasibility of eating and drinking during a condition of weightlessness. The studies, conducted by the School of Aviation Medicine, Randolph AFB, Texas, employed a Lockheed F-940 following a parabolic flight path that afforded interludes of weightlessness as high as 45 seconds."

Earlier reports which considered the possibilities of adverse effects due to disorientation were pessimistic. It was thought that vertigo, induced by disorientation, would create a situation making digestion all but impossible.

The element of appetite in this respect would seem to be related to individual adaptability to the situation. Flights in the X-1 and X-2 airplanes suggest that vertigo would not appear if the pilot kept his eyes open and thus maintained the visual element of the orientation trial. Compensation presumably kept the orientation from collapsing altogether.

Ingestion would not present serious problems insofar as valve action of the body is concerned. Food placed in the mouth would be retained by the confining action of closed lips. The main problem apparently is preingestion status of the nutritive material. Solids may be confined by their structural nature (as in sandwiches) or by continers, and liquids introduced either as part of the solid material or administered by squeeze-type bottles.

Liquids and solids, reduced to a paste-like consistency, may require some help from the tongue to move them into the esophagus. This skill should be acquired with a minimum of practice.

Digestion, including the later-phase process of assimilation, runs into the problem of digestive fluids dispersing into foam, and may, according to Buettner, tend to isolate the food material to be processed from the peristaltic agencies of the alimentary tract.

The solution here appears to be the inclusion with the food of a defoaming agent which is compatible both with the food and the organs of the body performing the various digestive processes. No data has yet appeared on these, but no serious problem is evident at present.

The only problem in elimination is disposal. Special toilet installations, or some such local device as centrifugation, might solve this.

Radiation

Two types of radiation hazards must be considered as cumulative in their effects. No impediment to appetite, ingestion, digestion, assimilation or elimination is known in the sense of immediate effect.

One major source of radiation likely in space is bombardment by cosmic ray particles.

Cosmic radiation may manifest itself in two ways—action on food and action on the body. Buettner says categorically that "radiation hazards to food may be safely excluded since cosmic radiation in this respect is completely harmless." This is not surprising on reflection, as radiation using atomic energy is currently contemplated. The scientists seem to be very confident of the general feasibility of the idea and are worried mainly about such groups of food as dairy products, which stubbornly resist irradiation processing for preservation.

The effect of cosmic radiation on human beings is another matter, because the impact of particles on cellular components, notably nuclei, is thought to be quite capable of pathological effects. The difference of opinion on the matter is somewhat curious. The only thesis the optimists can defend is that the radiation intensity has been greatly overrated.

If there is division of professional opinion on so basic an aspect of cosmic radiation, there is not much hope for a concise description of general cosmic radiation and its specific effects on humans. To treat it as analogous to atomic radiation, with certain obvious exceptions, seems logical, but not more than this can be said at the present time. Cosmic ray biologists are still determining the best type of specimen to send aloft.

One is left with the cautious supposition that cosmic ray sickness will manifest the same symptoms as atomic radiation sickness, and thus have the same effects on the alimentary processes. Human tolerance to gamma rays is about 0.5 roentgen.

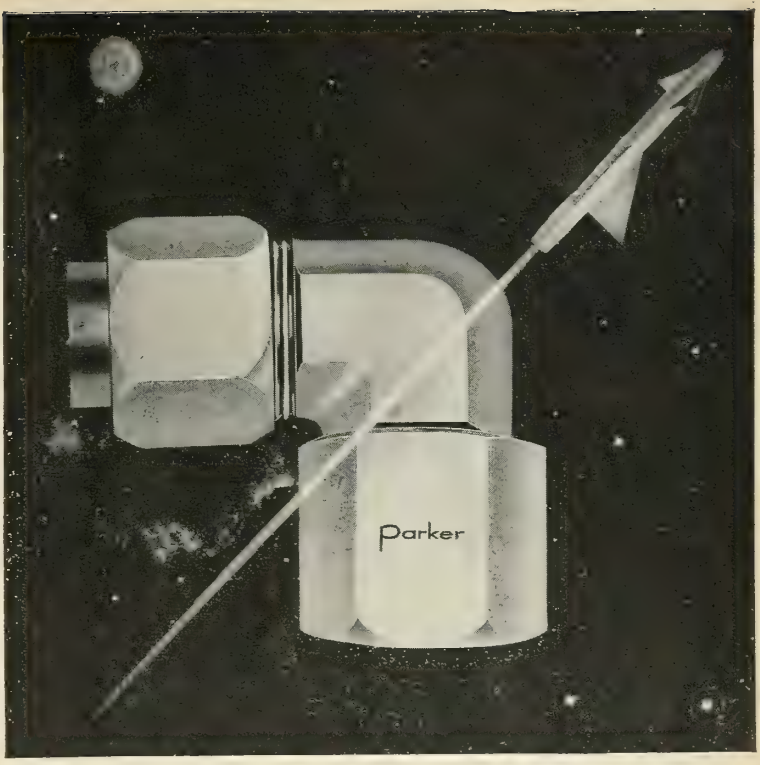
Overirradiation produces vomiting, then fever, diarrhea, weakness and progressive anemia. Hemorrhages result from impairment of blood-clotting mechanisms. The reduced white blood count would handicap the victim in event of exposure to disease. Space flight may be harmless, hazardous or suicidal, depending on the flux density.

Careful Selection

It is assumed that the crew has been carefully screened for emotional stability and general good health, using the same high standards as in the selection of jet fighter pilots. It is further assumed that sanitation and toxicological hazards have been taken into account in the design of the ship.

Nutritional substance must be adequate in quantity, well balanced, palatable and provide adequate body energy. Adequacy of quantity requires extreme compactness. Some improve-

ment along this line has been noted in conventional food merchandising, notably in frozen foods, dehydrated products and sometimes in the techniques of meat cutting. This is not enough for the logistics of space flight.



Some effort has been devoted to tabletized and other forms of concentrated nourishment. There are two opposing schools of thought on whether or not the body can safely survive with bulkless food. One school maintains a certain minimum is required to maintain conventional gastrointestinal peristalis. The other school points to the fact that the body accumulates and voids itself of waste long after the last food ingested has been eliminated. However, there is no record of an experiment where subjects attempted to subsist completely on superconcentrated foods and water alone. Meanwhile, it would be folly to assume that bulkless, tabletized foods can be trusted for long sojourns into space.

Another aspect of the nutrition problem is preservation, which often requires refrigeration and always asepsis. Food kept outside the vehicle and in shadow will be adequately refrigerated, and space is certainly sterile. A food product or concentrate which required neither would be very convenient.

Algae has been advanced as a food substance and is presumably fairly rich in carbohydrates. The present state of the art indicates a good start, but algae is not yet at the point where it is a very serious contender to other forms of food except insofar as it does regenerate itself. The Arthur D. Little Co. has in operation a pilot which measures 600 square feet in area and with 1200 gallons of culture produces somewhat over 0.75 pounds of dried algae per day. The quantity of useful food substance from this has not been determined, but is surely not 100 per cent. Even if it were, this is hardly enough to provide adequate nutrition for human beings even with a zero margin for error. If the vehicle is sufficiently large, it might help in providing part of the daily requirements.

Palatability complicates the nutrition problem and algae does not stand out in this respect. It does not whet the appetite nor encourage ingestion in the average person. Artificial preparations have an advantage here, as palatable additives enhance the overall acceptability.

What remains is a synthetic food concentrate, which is light, compact, balanced, palatable and requires little or no refrigeration or post-packaging asepsis. Concepts on nutritional adequacy will have to be altered to fit the needs of space flight. ★

Parker Triple-lok fittings stand up under severest temperatures and stresses

Exhaustive tests by Parker and by missile builders prove that Triple-lok tube fittings stand up under the severest punishment of rocket stresses and strains, high pressures and temperatures . . . give you leakproof, dependable, *safe* connections.

Used on missiles and launching pads, Triple-lok fittings simplify construction, provide trouble-free connections, last longer. No matter how close the quarters, or how intricate the system, Triple-lok fittings are fast, easy to install.

Will even hold helium. Parker Triple-lok fittings can be furnished with specially treated flare nose surface that will trap even elusive helium, which no ordinary metal-to-metal seal can do.

The industrial standard. Triple-lok fittings come in a wide range of sizes and shapes (including *straight* threaded and *female* pipe threaded bodies). Available in type 316 stainless steel; in other alloys on special order. Warehouse stocks in all industrial centers. Ask your Parker Distributor for Triple-lok Catalog No. 4310, or write to —

The F-94C aircraft used in parabolic flight to obtain reduced gravity states.

Progress in Space Medicine

By Maj. Gen. Otis O. Benson, Jr.

Commandant, School of Aviation Medicine

THE LARGER portion of the atmosphere, from the standpoint of human flight, is not unlike interplanetary space, if we ignore some conditions caused by the presence of the solid body of the earth itself. This knowledge makes us realize that space operations in the form of space equivalent flights are here and are of immediate interest to the Air Force.

In the *preliminary* phases of space operations most of the medical problems are encountered as they most probably exist in the *more advanced* and *final* phases of space operations, such as in interplanetary space travel. The main difference is the duration of the flight.

One of the most important medical considerations is engineering of the cabin of a space vehicle from the standpoint of human factors. This must be a development of close cooperation between the engineer and the biomedical scientist.

The cabin, of course, must be completely sealed. It is interesting to note that such a space cabin is required at altitudes as low as 70,000 to 80,000 ft. This cabin is not pressurized by the use of outside air, but rather must be pressurized from within —a self-sustaining system. It is the task of Space Medicine to provide the crew with the best possible artificial atmosphere providing adequate barometric and oxygen pressures. Removal of carbon dioxide produced by the crew in respiration is of special importance.

Other problems include humidity control, temperature control and odor removal. The magnitude and complexity of these technicophysiological problems require careful experimental studies in the laboratory.

On the vertical frontier opened by the rocket, human factors will play an important or even a decisive role. The medical problems involved in rocket or space operations are the subject matter of Space Medicine, a branch or an extension of Aviation Medicine. During the nine years that Space Medicine has existed as an organized entity, considerable progress has been made in both theoretical and experimental considerations. Here, briefly, is an updating.

Such studies are possible in experimental hermetically sealed cabins, such as the so-called space cabin simulator at the School of Aviation Medicine. This experimental device is different from altitude chambers where body reactions under decreased air pressure are studied. In contrast, task of the space cabin simulator is to *take care* of its occupants. Considerable progress has been made in this research field.

A Lesson From Plants

Experiments have been carried out for periods up to 24 hours under normal barometric conditions, and for a number of hours under reduced pressure corresponding to an altitude of 24,000 ft. Similar studies have been done in sealed gondolas for high altitude balloon flight at the Aero Medical Field Laboratory at Holloman AFB.

In space operations of longer durations, the scope of the problems will increase. New methods for the regeneration of cabin air may become necessary from the standpoint of economy. One means to accomplish this is the production of oxygen and removal of

If your problem calls for

MISSILE GO-NO-GO TESTING

Link's Design, Engineering and Production Abilities Provide the Answer

Link has established an enviable record of achievement in the design, development and manufacture of Go-No-Go systems evaluation test equipment. With this experience, Link serves many industries confronted with problems in the field of electronics.

In addition to test equipment, Link's know-how in the rapidly-changing electronics industry covers many other areas, including:

- Simulators
- Evaluators
- Optical Systems
- Ground Support Equipment
- Component Assemblies
- Computers

Experience, highly specialized engineers, and modern, complete production facilities enable Link to custom-build electronic equipment for many missile applications. Each item of equipment—a result of continuous research and development, imaginative management and stringent quality control—is the most advanced in its field.

Link can be of assistance in solving your problem. Write or call Jack Ritchie, Engineering Sales, Binghamton 3-6311 (ext. 277) for complete information. A brochure of our facilities is available on request.

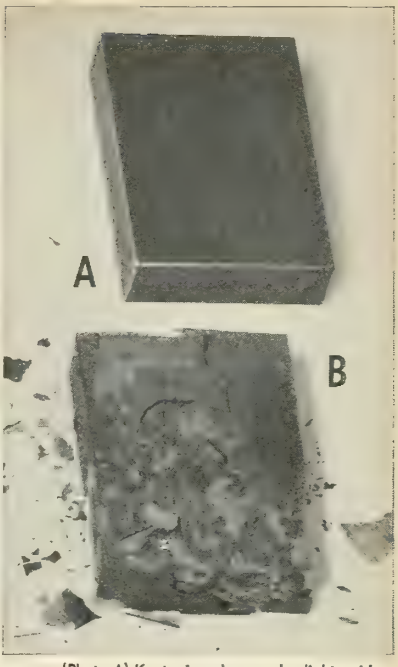
carbon dioxide with the aid of photosynthesis as it occurs naturally in plants.

In experimental studies sponsored by the School of Aviation Medicine and carried out by Dr. Jack Myers, head of the Department of Algal Physiology, University of Texas, it has been found that five pounds of a species of alga are sufficient to supply the respiratory requirements of one man. These studies are being pursued and more data are being obtained.

Maj. Gen. Otis O. Benson, Jr.
Commandant, School of Aviation Medicine

Of course, in space equivalent flights and space operations of short duration, we will never resort to such a photosynthetic gas exchanger because of the weight and volume of such a device. For space operations of long duration it might be a different story; and under such conditions, the elimination and reutilization of waste products may become necessary. Developmental studies in this direction will make the scope of the physiological problems involved in a closed ecological system complete.

Problems of another nature, such as the psychological behavior in closed systems, will also enter the picture. Such studies are under way.



External Protection

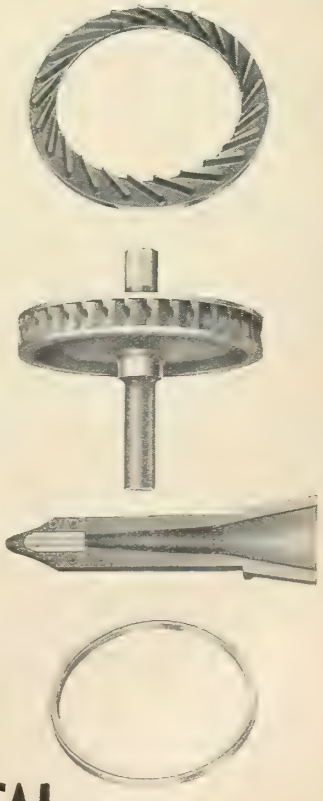
A space cabin also must be equipped to protect the crew against external factors, such as meteorites and cosmic ray particles. Here is a fruitful field for close cooperation between the astronomer, astrophysicist, engineer and the bioscientist.

Insofar as cosmic rays are concerned, we are much better informed today as a result of theoretical calcula-

KENTANIUM*

unharmed at 2000°F while → heat-resistant nickel-chrome alloy disintegrates

(Photo A) Kentanium shows only slight oxidation after test and is good for many more hours' exposure at 2000°F. (Photo B) Hard nickel-chromium (35%) alloy is badly oxidized and began to disintegrate during test.



Exceptional resistance to oxidation, combined with great strength at very high temperatures, are characteristics of Kentanium, a titanium carbide composition. Here's proof.

A square of K161B Kentanium and a similar square of a well-known, heat-resistant 35 chromium-15 nickel alloy were exposed for 120 hours in an unsealed muffle furnace heated to 2000°F. The accompanying photographs vividly show how each piece was affected. While Kentanium is still good for hours of exposure at high temperatures, the nickel-chrome alloy has oxidized badly and has begun to disintegrate.

This demonstration suggests how well Kentanium will perform in such applications as furnace parts, heat-treating fixtures, quench guide rings, turbine blades, nozzle vanes, bushings and other parts where strength at high temperature, plus high resistance to oxidation, are factors.

Parts illustrated at the right are typical applications of Kentanium. The Kentanium series represents only a part of Kennametal's wide range of hard carbide compositions that are helping designers who require metals offering high resistance to abrasion, deflection, deformation, impact or corrosion. Perhaps one or more of these Kennametal compositions will help you get your idea off the drawing board into production. These materials are described and many applications discussed in two booklets: B-111-A—"Characteristics of Kennametal," and B-222—"Designing with Kennametal."

Space cabin simulator used at Randolph AFB to study human reactions.

tions and experimental observations from high altitude balloons. For short-time exposure at altitudes where the primary cosmic rays are encountered, the situation is less dramatic than was thought some five years ago. With regard to flights of long duration, however, the question of health hazards from exposure to cosmic rays remains unanswered.

In the experimental sealed cabin we can simulate a number of space flight situations; but one condition that can hardly be produced in the laboratory is that of the state of weightlessness. Comparative studies have been made in a swimming pool, in which some of the features of weightlessness are achieved.

For a more complete understanding of zero-gravity and its biological effects during actual flight we must produce the "real thing"—namely, weightlessness in flight.

The method of producing weightlessness in parabolic flight maneuvers in jet planes is now pretty well understood. Control systems have been developed and a significant number of experiments have been carried out at the Aero Medical Laboratory, Wright-Patterson AFB, Ohio, and at the Aero Medical Field Laboratory, Holloman AFB, N. M., as well as at the School of Aviation Medicine.

These studies are designed to determine the performance of man under a state of reduced gravity to the point of weightlessness and to assess his tolerance to this strange situation. From current data, inference is drawn that man adapts very well to fractional gravity states of short duration.

Tests To Date

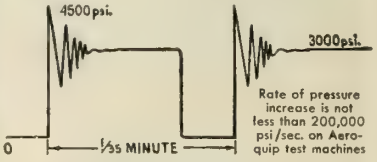
The experiments of Dr. S. J. Gerathewohl of the School of Aviation Medicine have shown that about 25% of the subjects became moderately nauseated during maneuvers associated with parabolic flight, 25% were relatively indifferent, and the majority of human subjects enjoyed the experience. These and other studies, extremely important to engineers and bioscientists, must be extended over longer periods of weightlessness before final conclusions can be drawn. Our preliminary observations may have a bearing upon the ultimate selection and training of aircrews for space operations.

This is only a very brief survey of the problems and interests of Space Medicine and its progress. From the fueling of a rocket vehicle through its launching and flight, its re-entry into the atmosphere and ultimate descent, the bioscientists are attempting to identify the problems and obtain solutions.

Toxicity of propellants, forces of acceleration during launching, and deceleration forces upon re-entry are under study in terms of their effects upon the personnel.

The elements of discrimination, decision and judgment still dictate that man is superior to the "black box" in innumerable situations and that he hasn't been ruled out for space flight operations. Our interests always are in the man who flies—from ground level to infinity. ★

Aeroquip



Engineering Notes

B. A. MAIN, JR.

The advertisement at the right reveals a new construction for high pressure hose of Teflon. Naturally there is a reason for going to this type of construction and I'll try to show here why we did it.

The most widely used measuring stick for evaluating high pressure hose is the impulse test. In this test, the hose line is subjected to hydraulic impulse pressure varying from 0 pressure to 3000 psi., with a surge peak pressure which reaches 4500 psi. The pressure curve shape is shown below:

Rate of pressure increase is not less than 200,000 psi/sec. on Aeroquip test machines

A hose line is considered adequate if it will withstand 100,000 cycles or applications of this pressure curve, and in the case of hose of Teflon, the fluid in the hose and the ambient air surrounding it must be held at 400° F.

We began this development by building and testing hoses using conventional two-wire braided reinforcement around the inner tube of Teflon. In the -4 size, two wire braids proved to be adequate reinforcement to withstand the impulse test, each time samples were tested.

In the -6 size, we tested many constructions of two-wire braided hose of Teflon. We explored both 302 and 304 stainless steel wire in sizes from .011" to .015" diameter. We also explored the use of carbon steel wire for the inner braid using various wire sizes. Twelve separate impulse tests involving hundreds of samples were necessary to investigate all combinations; in every case one or more samples failed before completing the 100,000 cycles of impulse. Our experience with the -8 size paralleled that with the -6 size.

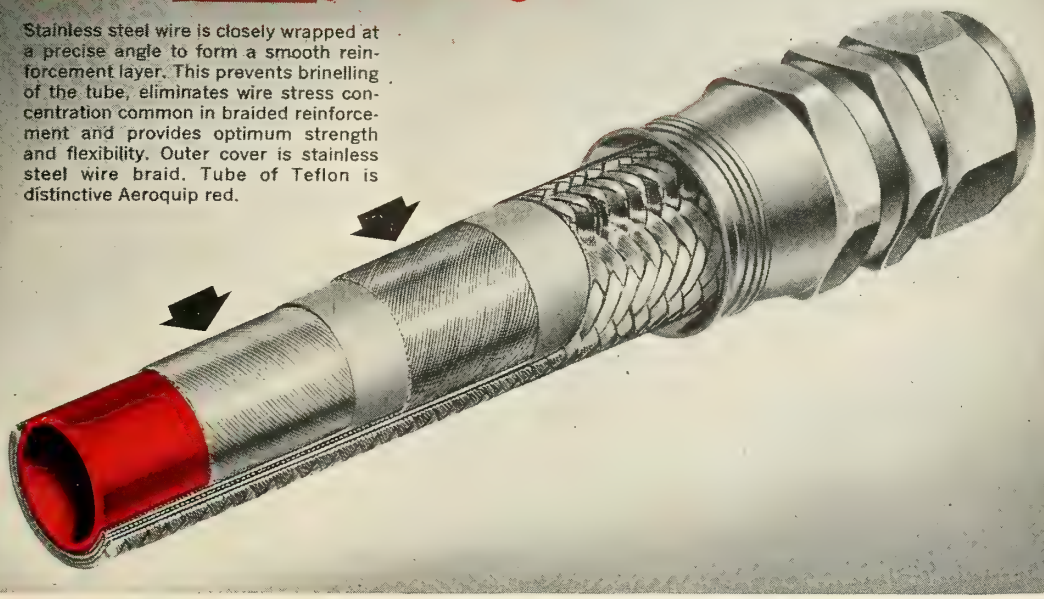
The failures always begin with the inner braid. Here, individual wires break at the crossovers which are formed when wires are first brought over and then under other wires in braiding. As soon as a sufficient number of the individual wires break, the hose bursts during the test.

The obvious solution to this problem was to eliminate the crossovers of braiding by substituting the two spiral wire wraps for the inner braid. This required new machinery and techniques, but we now produce the hose successfully.

We have now finished six separate impulse tests successfully on the -6 and -8 sizes. The samples tested have included both carbon steel wire and stainless steel wire for the spiral wraps and both wires passed the 100,000 cycles every time.

Work on this project has convinced me that it is impossible to build a braided hose size -6 and larger which will withstand this impulse test every time the hose might be subjected to the test.

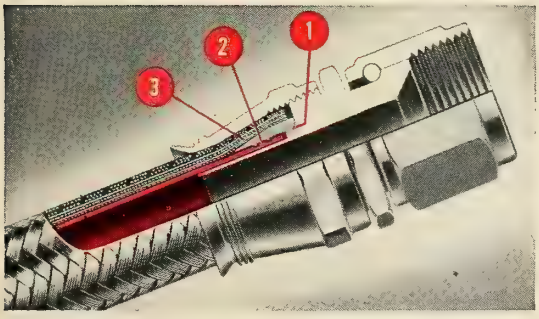
In our tests of the -6 size we did have two successful tests of braided hose, but when these were retested the samples failed, so you can't judge by one test alone.



The spiral construction provides the best high pressure hose available today. It can be used at the same bend radii as equivalent two-wire braided hose, and compares nearly exactly in weight and size.

B A Main Jr

VICE PRESIDENT, ENGINEERING
AEROQUIP CORPORATION



SPIRAL WRAP
adds lasting strength

Stainless steel wire is closely wrapped at a precise angle to form a smooth reinforcement layer. This prevents brinelling of the tube, eliminates wire stress concentration common in braided reinforcement and provides optimum strength and flexibility. Outer cover is stainless steel wire braid. Tube of Teflon is distinctive Aeroquip red.

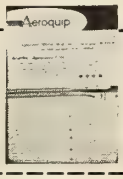
Specify Aeroquip 677 Hose of TEFLON* and Reusable "*super gem*" Fittings for 3000 psi. Systems

GET ALL THESE IMPORTANT ADVANTAGES:

Leakproof, too! This cutaway view shows how Aeroquip "*super gem*" Fittings protect against leakage at all pressures: **(1)** a metal-to-metal line seal; **(2)** a lip seal formed by the tube of Teflon seated, but not compressed, between the nipple and sleeve. Compression of wire reinforcement **(3)** assures positive grip and lasting protection against fitting blow-off.

*DuPont trade name for its tetrafluoroethylene resin.
"*super gem*" is an Aeroquip Trademark.

Hose Strength that lasts and lasts! The secret is in the hose construction perfected by Aeroquip . . . multiple spiral wrap reinforcement that resists impulse fatigue and prolongs the life of the hose line.



Reusable "super gem" Fittings that cut costs! Fittings are often the most expensive part of a hose line, well worth saving when engineering or production changes call for fluid line alterations. With "*super gem*" Fittings you save ALL, not part, of the fittings. Hose line assembly and disassembly is quick and easy, using ordinary bench tools.

High performance, high temperature hose lines of Teflon especially designed for 3000 psi. aircraft systems by the leading producer of hose lines for aircraft applications. Mail the coupon below for complete information.

rocketeer profile

Pied Piper Bob Truax

By Erica Cromley

. . . a glimpse behind the braid of the man who spurred the Navy's rocket program

CMDR. ROBERT C. TRUAX is said to be the only man ever to fire a rocket in the engine room of a U.S. naval vessel. Let us hope so. A man who has earned many honors for his "firsts" in Navy rocketry, Bob Truax feels this is one tribute he can do without. He claims innocence.

The Navy's rocket expert does admit, however, that he rigged up a rocket engine test stand aboard the USS *Enterprise* in 1940 and continued the rocket experiments he had begun as a teenage Naval Academy midshipman in the late 1930s. Although the shipboard project was encouraged by the skipper, Navy sources say there was an audible sigh of relief when the young rocket enthusiast was assigned to the Bureau of Aeronautics. Bob Truax, now 39, has lived rockets since his boyhood days when he did his rocket tinkering in the basement. While a midshipman at the Naval Academy he badgered everybody and anybody for bits, parts and pieces from which to make a rocket engine. The U.S. Naval Engineering Experiment Station near Annapolis helped him build a test stand.

He was unable to evoke a single explosion, but six years later in 1945, after he had graduated and was back at the test station, he effected what he describes as a "doozie." It shattered bulletproof glass. The device—a nitromethane engine.

In August 1946, he was ordered to BuAer in charge of rocket powerplant development, having, in effect, sole responsibility for BuAer's progress in this field—a $6-million-a-year project.

Among the projects he mothered were development and test of the powerplants for the D558-2, the *Viking* and the earth satellite vehicle (1946-1948).

Says the rocketeer in recollection, "At this time I completed a study of a long-range [1100-mile] ballistic missile for fleet use and succeeded in getting BuAer endorsement on a program to develop this missile. The program was rejected by the Chief of Naval Operations. This engine is slated for use in the NAA X-15 airplane."

Four years later, with a master's degree in nuclear engineering, he was assigned to head the BuAer surface-launched branch of the guided missile division. Here he supervised the *Rigel, Lark, Regulus* I and II projects.

He says of this stint: "My duties also included proposing new projects. I vigorously advocated initiation of a ballistic missile program and an anti-ASW missile of original concept."

In the fall of 1954, he was borrowed by the Office of Naval Research to study the problem of fleet air defense. His report, submitted six months later, resulted in sweeping changes in the missile radar control equipment and shipbuilding programs. He still has the letter of commendation from the Chief of Naval Research for this work.

Bob Truax, perhaps more than anyone else, was responsible for getting the Navy started on its rocket program. However, the Navy apparently didn't move fast enough for him and it wasn't long before the Air Force requested that he be assigned to its ballistic missile program.

Currently the naval rocket pioneer channels his talents into the Ballistic Missile Division Headquarters, Air Research & Development Command. Title: Deputy Director, USAF Ballistic Missile Division.

Since he joined Maj. Gen. Bernard Schriever's staff, Bob Truax has been working on the Air Force' reconnaissance satellite project, frequently referred to as Project *Big Brother*. The project's name, however, is *Pied Piper*.

This satellite, which was originally part of President Eisenhower's open-skies plan, started out as nothing but a study project. Today the project has come to life, more money has been granted for it, and Bob Truax is expected to be stuck with it for some time to come.

Only a few of the Truax achievements in rocketry are recorded here. He has received awards from various scientific associations for his work, has published many papers and reports of inestimable value to other rocketeers and holds seven patents for aero-rocket devices. He was a director of the American Rocket Society from 1947 to 1950 and is about to step down as its president next month.

In tribute to his work, the Navy has a couple of honors in the works: the Legion of Merit Award "for his continuous outstanding service in the field of rockets and missiles," and a promotion to captain.

Considering his achievements, a portrait would emerge of an intensely

The Truax talents run in many directions. This is the Truax-designed home in Arlington, Va.

Junior and Senior Truax sea-shelling on family weekend trip.

Posing for dad. Ann, 15; Kathleen, 13; Steven, 11; Gary, 6.

dedicated, senior, introverted science type, with no time for anything but his life's work. Not so.

Bob Truax takes his work seriously; himself, not. He has a tremendous zest for living which is immediately apparent on meeting him. He resembles nothing so much as an exuberant undergraduate (crew-cut included) who has just received a bigger check from home than he expected.

The 39-year-old rocket whiz has been termed by his friends as magnetic and dynamic, with boundless energy and countless friends. Said one, "I have never heard him say an unkind thing about anyone." His co-workers all use identical phrases when they describe him: extremely dedicated, gets along well with everybody, farsighted, extremely modest and not aware of his greatness.

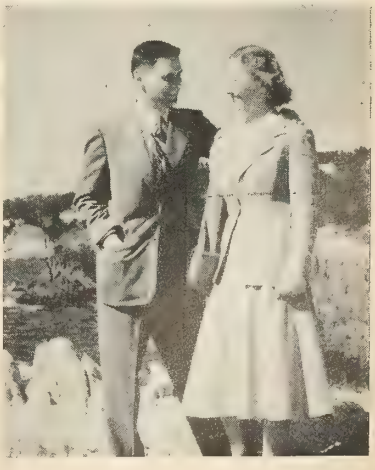
He has a flair for expressing himself well which puts him in great demand as a toastmaster. Though modest about his rocket achievements, the Truax pride is vocal where his family is concerned. There are four junior Truaxes ranging in age from six to 15. None of them are basement rocket tinkerers. Six-year-old Gary is more interested in making airplanes, collecting bones and skulls. He also likes to draw spaceships. "Watch today's kids," says father Bob. "What they draw today may well turn out to be the designs of tomorrow."

Steven, 11, who just became a boy scout, gets his kicks on the baseball diamond as a Little Leaguer. Kathleen, 13, is taking art lessons, and 15-year-old Ann, who wants to be a nurse, has her head buried in first-aid books.

Indirectly, rockets were responsible for Rosalind and Bob Truax getting together. In 1938 during a search for a refractory material for a nozzle, he met Carl Schroeder, a metallurgical engineer from New Jersey. At the invitation of mutual friends, Schroeder and Truax met to talk over nozzle problems. The friends also invited Schroeder's daughter, Rosalind. This led to an invitation to the hop at Mem Hall, a three-year courtship and a trip to the altar in July 1941.

They set up housekeeping in Annapolis. Here Bob Truax started on the JATO development project at the Experiment Station a few months before Pearl Harbor. They have moved 22 times in the 16 years since.

The commander describes his current home as a "typical California tract house, what you call a rambler though this one doesn't ramble far." They're renting. Home is in Arlington, Va., a Truax-designed house complete with work-saver cabinets. "A showplace," he says in a rare burst of immodesty.



The Truaxes are outdoorsy types. There are family hiking and camping weekend trips. A recent such excursion took the family on a canoe trip down the Colorado River.

He looks forward to spending time with his family but admits it is not nearly as much as he would like. The experiments still go on in the basement where he concocts electronic devices using the "cookbook" method. And like many a cook, chef Truax's concoctions do not always turn out as planned. Once he started out to make a Geiger counter and wound up with a computer. He expects to track *Sputnik* with a six-inch reflecting telescope of his own making.

Bob Truax is a nonsmoker, nondrinker and easy to please in the food department. Preferences run to hash, and macaroni and cheese. This may be more than a matter of choice. In addition to six Truaxes, the Navy rocketeer supports two cats, one black cocker and a horse. Dog is named Jet. Horse is named Rocket. Of course.★

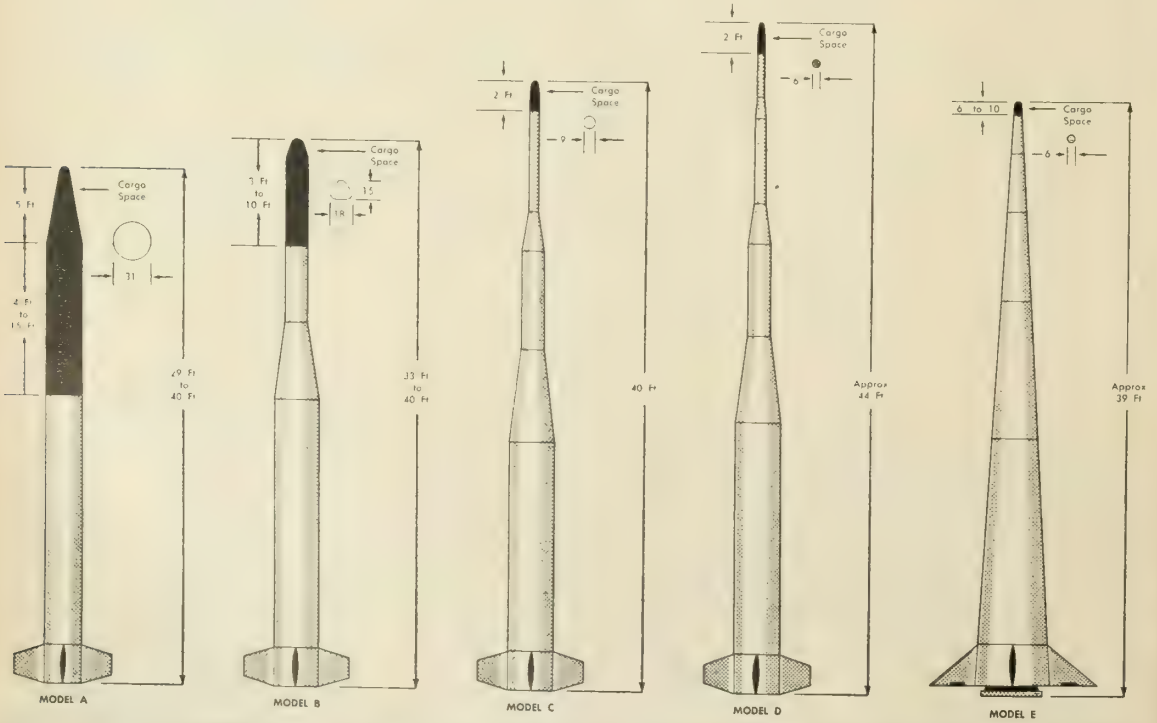
Below—Hometown father and son game in Rolling Hills, Calif., with Father Bob at bat.
Right—The Truaxes at Monterey, Calif. They have moved 22 times in the past 16 years.

MISSILE AGE

By Norman L. Baker

Lockheed Offers Satellite and Moon Rockets

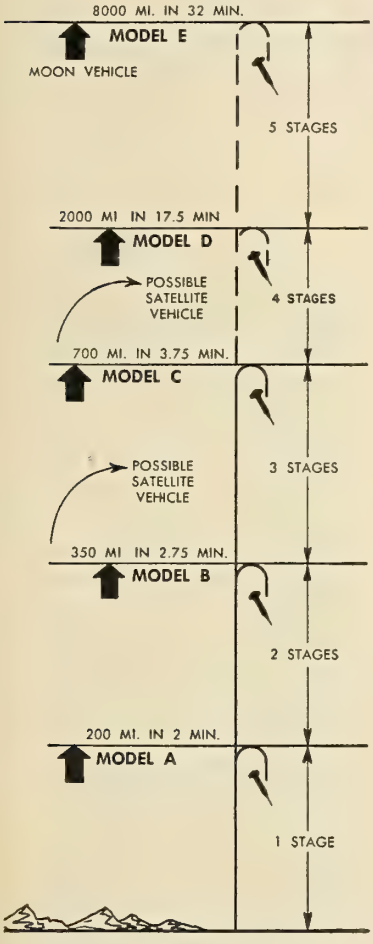
The Missile Systems Division of Lockheed has proposed a practical, realistic approach to the task of gathering upper-atmosphere data desperately needed in our ICBM, anti-ICBM, satellite and missile programs. The beauty of the Lockheed proposal is the use of a family of research rockets evolving from the successful X-17 re-entry test vehicle that will reach altitudes ranging from 200 to 8000 miles up and out. Most advanced models could reach orbiting and escape velocities.



Designated *Explorer,* the series consists of five models ranging from one to five stages. The vehicles combine a wide range of payload and altitude capabilities with reliability, safety, simplicity and easy portability. Rocket motors are "off the shelf" solid propellants, developed by the Thiokol Chemical Corp., that have been thoroughly flight-tested in previous operations. The staged vehicles use a combination of *Sergeant* and *Recruit* rockets. The *Recruit* is the same rocket that is used in the four-stage *Far Side* vehicle.

The performance characteristics of the *Explorer* models make them acceptable for geophysical and communications data gathering. The high g accelerations (100 g) expected with this type of vehicle make them unsatisfactory for the evaluation of components or equipment sensitive to rolling or high g forces. A vehicle incorporating roll stabilization and guidance is now under study and will meet the requirements needed for evaluating highly sensitive components in the ICBM and AICBM programs.

It became obvious during the X-17 program that a vehicle of similar capabilities could be utilized to investigate the problems beyond those of immediate concern to the ICBM re-entry phase. A re-evaluation of the X-17 vehicle resulted in the *Explorer* series. The *Explorer* would embody the same dependability and portability as the X-17, but with a much wider range of capabilities.



Model A

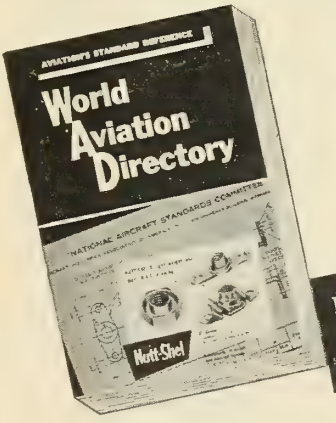
This is a single-stage vehicle utilizing the Army XM-20 *Sergeant* sur-

MODEL A: XM-20 SERGEANT, gross weight 9000 lbs., thrust 50,000 lbs., MODEL B: gross weight 10,000 lbs., thrust (first stage) 50,000 lbs., (second stage) 104,000 lbs., MODEL C: X-17 research re-entry vehicle, gross weight 10,400 lbs., thrust (first stage) 50,000 lbs., (second stage) 104,000 lbs., (third stage) 34,000 lbs., MODEL D: gross weight 10,459 lbs., thrust (first stage) 50,000 lbs., (second stage) 104,000 lbs., (third stage) 34,000 lbs., (fourth stage) 1680 lbs., MODEL E: gross weight 19,000 lbs., thrust (first stage) 62,000 lbs., (second stage) 115,000 lbs., (third stage) 37,300 lbs., (fourth stage) 8100 lbs., (fifth stage) 1800 lbs.

face-to-surface missile powerplant. The cargo compartment, 31 inches in diameter and four to 15 feet long, could carry from 100 to 500 pounds of instrumentation. Its ability to remain at peak altitude of 200 miles for as long as two minutes makes it suitable for collecting geophysical data. As a testing range instrumentation vehicle, with a payload of 100 pounds, it would have a range of 400 miles and an apogee of 50 miles.

Model B

This two-stage model would use a *Sergeant* first stage and three *Recruit* rockets for the second stage. The aerodynamic design has already been proved in flight. Instrumentation payload could weigh from 80 to 500 pounds. It would be capable of remaining near peak altitude of 350 miles for almost three minutes.



Model C

Identical to the X-17, this three-stage model has a *Sergeant* motor for the first stage, three *Recruits* for sec-

NEW FINE PITCH GEAR ACCURACY

GERITE*
Gear Generating Machine
Remarkably accurate,
extremely versatile,
ideal for short runs.

Faster, more accurate Fine Pitch Gear production and quality control with these 4 Illinois Tool Works developments

Get higher standards of accuracy, reduce rejects and avoid wasted production and inspection time with this new ITW team in your plant. GERITE (above)—this machine permits tooling up and producing gears overnight! MICRITE*—for the first time an analytical check of fine pitch gear involute profile. MICRAC*—automatic charter utilizing precision ground master worm. Accurate to .0001, ideal for production checking. GEAR ROLLING INSTRUMENT—provides extreme accuracy and economical inspection on the production line.

(*Trade Mark)

ond stage and a single *Recruit* for the last stage. With a 50-pound payload it has a peak altitude of 700 miles or 350 miles with a 250-pound payload. The payload space is nine inches in diameter and two feet long.

Model D

This four-stage rocket, and the Model E, would require further development in order to achieve the desired ranges of altitude and payload capabilities. Requiring only a mimimum of development, the Model D could be made by adding a fourth stage rocket, similar to the *Arrow*, to the Model C. It would carry a 10-pound payload to an altitude of 2000 miles. It would place its payload near peak altitude for almost 18 minutes.

Model E

Lockheed states that this version is based on a proven and reliable design concept with capabilities of extending measurements into the region from 2000 to 8000 miles above the surface of the earth. Using currently available solid propellants, it is expected to exceed satellite orbital velocities. Escape velocities are possible with recent propellant improvements. This rocket vehicle could, with adequate guidance, transport a payload to the surface of the moon. Preliminary design results indicate that a cargo space six inches in diameter and six to 10 inches in length will be available for a payload of 10 pounds.

In addition to the basic vehicle, Lockheed could make available all the necessary equipment and organizational capabilities for use with the *Explorer* flights. The equipment includes the launcher, umbilical stand, mobile crane, handling slings, mobile scaffolding, forklift, and tractor and lift-trailer combination for towing and erecting the missile.

The original Lockheed proposal for the *Explorer* research vehicles was made at the beginning of the IGY. It was well received by the National Committee for Rocketry and Meteorology, but due to lack of funds for further programing the *Explorer* project is still in the planning stage.

Lockheed's approach to the missile and space research program is indicative of the realistic thinking of some of the top planners in our research programs. A recent example of this approach was the *Far Side* project.

Few companies holding large defense contracts are willing to become involved in a low cost, small quantity production item like the *Explorer*, especially when the major components of the vehicle are manufactured by another company.

Litton Chamber Probes Space Conditions

An inhabited high-vacuum laboratory has simulated the pressure conditions that prevail 95 miles above the earth.

The laboratory is an invaluable research tool in performing fundamental studies needed for the development of outer space weapon systems.

Niels Jensen, a scientist from Litton Industries, Inc., Beverly Hills, Calif., has been working inside the 15-foot long, eight-foot diameter "high-vacuum" chamber with only a special pressure suit to protect him against the simulated conditions that exist in the thin atmosphere.

Protected by the unique pressure suit with its external system of oxygen supply and heat removal, an operator can inhabit the vacuum of the chamber and perform intricate research.

The laboratory will be used to facilitate the advancement of knowledge about the behavior of physical phenomena, equipment and instrumentation under conditions of extremely low pressure and density.

Also to be explored by the new laboratory is the chamber's applicability to electron-tube research.

Grand Central Builds Rocket Fire Fighter

The U.S. Forestry Equipment and Development Center at Arcadia, Calif., is evaluating the *Little Vanguard* solid-rocket-propelled forest fire extinguisher. Developed for Grand Central's own protection on its 8000-acre

mountain-walled test site, it first attracted national attention when a mass firing was demonstrated publicly.

It is a solid-propellant-powered missile slightly over 54 inches in length and is launched from a simple wooden trough. Payload is 8.5 gallons of borate or 76 pounds of other material. On impact it covers a splatter area of 700 square feet. Range is 410 yards with one rocket motor or 1200 yards with two motors.

Aeronutronic Plans for Advanced Missiles

Aeronutronic Systems, Inc., Ford Motor Co.'s West Coast subsidiary, has leased 100 acres and optioned a like amount as a site for its new multi-million-dollar research and development center near Newport Beach in Southern California.

Construction will begin immediately on the first unit, a series of aerothermochemical laboratories to explore problems associated with the design of advanced missile systems. These include anti-missile systems, reconnaissance systems and upper atmosphere vehicles. April 1958 is the targeted completion date for the first phase.

Propeller Company Turns to Rockets

For many years a byword in the propeller manufacturing field, Hamilton Standard is offsetting the problems of reduced defense appropriations and declining volume of business by greatly expanding their missile efforts.

Hamilton's latest expansion, a 410,000-square-foot building, will move them still more firmly into the jet propulsion era. It is probably the largest facility built solely for the development, testing and production of controls for turbine, atomic and rocket engines.

Hamilton Standard currently is producing air conditioning systems, turbine starters, hydraulic pumps and pneumatic valves as well as fuel controls, and is developing still newer products for the turbine and missile fields.

American Rocket Co. Plans Lithium Production

American Rocket Co. announces that it has been working on lithium rocket propellants for about a year. The high-energy propellants are based on lithium perchlorate, nitrate and other chemicals. Both solid and liquid propellants have been formulated and are being evaluated.

Aerojet-General Awarded $55-Million *Titan* Contract

Aerojet-General was recently awarded a $55-million AF contract for *Titan* engine units. Fabrication and testing of the engines has been under way for several weeks at Aerojet's Sacramento plant.

Manufacture of the large engine components at AF Plant 70 is proceeding on schedule. *Titan* is a two-stage ICBM under development by The Martin Co. of Denver. First-stage engine thrust has been reported at 300,000 lbs., with second-stage thrust at 60,000 lbs. First flights of the *Titan* are expected shortly before January 1st.

Goodrich Increases Rocket Research Facilities

B. F. Goodrich Aviation Products has purchased land and buildings at Rialto, Calif., for expansion of their rocket research program. Goodrich, engaged in rocket propellant research since 1953, will continue research and development in this field in the Rialto location.

Vitro Labs Awarded *Terrier* Systems Contract

Vitro Laboratories, a division of Vitro Corp. of America, has been awarded a contract with the Bureau of Ordnance for systems engineering of *Terrier* guided-missile installations on new carriers of the *Forrestal* class.

The work covers installations on new attack carriers and a nuclear-propelled carrier which has been authorized for construction.

IS YOUR JET ENGINE RPM MEASUREMENT ACCURATE AND SAFE?

TAKCAL®

READS JET ENGINE SPEED to GUARANTEED ACCURACY of 10 RPM in 10,000 RPM (±0.1%)

The inter-relation of RPM to efficiency and thrust in jet engines is fundamental. Proper adjustments for maximum thrust, maximum engine life and maximum safety of operation can be made only upon accuracy of instrumentation. The TAKCAL tests to guarantee that accuracy.

The new B & H TAKCAL incorporates a refinement of the frequency meter principle. It operates in the low (0 to 1000 cps) range, reading the frequency of the tachometer generator on a scale calibrated in percent RPM corresponding to the engine's RPM. It reads engine speed while the engine is running with a guaranteed accuracy of ±0.1% in the range of 0 to 110% RPM. Additionally, the TAKCAL circuit can be used to trouble-shoot and isolate errors in the aircraft tachometer system, with the circuit and tachometer paralleled to obtain simultaneous reading.

The TAKCAL's component parts are identical with those used in the J-Model JETCAL Analyzer. They are here assembled as a separate unit tester and for use with all earlier models of the JETCAL Tester.

The TAKCAL operates accurately in all ambient temperatures from −40°F. to 140°F. Low in cost for an instrument of such extreme accuracy, it is adaptable to application in many other fields.

For full information write or wire...

CHECKS TACHOMETER "SYSTEM" ACCURACY. ADAPTS TO ANY FREQUENCY PROBLEM!

Explosion-proof TAKCAL for special applications. Measures 200 to 7500 RPM, direct reading, with ±0.1% accuracy.

West Coast Industry

By Fred S. Hunter

Have you heard of "Frescanar?" This is nomenclature for a frequency scanning radar technique Hughes Aircraft Co. has had under wraps since it was first conceived in 1948. First application is in the Hughes-developed AN/SPS-26 shipborne radar system recently installed by the Navy in a guided missile cruiser for sea tests and shipboard evaluation. Reports indicate that AN/SPS-26—an integrated electronic system for accumulating three-dimensional data on all airborne targets—has revolutionary capabilities. Tests on the first model of the surface pulse search system before delivery to the Navy are said to have been highly pleasing to the Hughes ground systems division which developed the antennas and circuits for the Frescanar technique. These tests included many hours of on-the-air operation at high power. The radar system also incorporates some new tube developments, notably a traveling wave tube designed by the Hughes microwave laboratory.

•

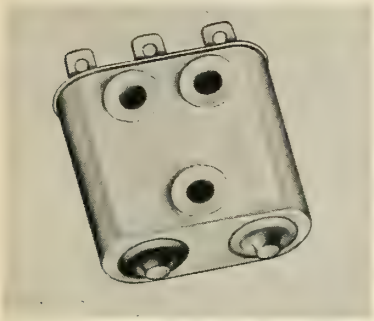
Aerojet-General will be back on schedule on solid-rocket production December 1 at Sacramento, where $500,000 worth of fire damage was incurred in two explosions about a week apart. Included in the repair is redesign of the No. 3 line to incorporate production improvements. Aerojet also has a brand new No. 5 line of the latest type going in at the Sacramento solid plant plus a new propellant chemical laboratory. When you mention a line at a plant like Aerojet's, incidentally, you aren't referring to a production line in the ordinary sense. You mean a group of five, six or seven buildings spaced apart and protected by revetments between one another.

•

Boeing now has its YIM-99 logistic depot in operation at Seattle for storage and distribution of spares for the service-test (Y) *Bomarc* interceptor missile, together with maintenance, repair, modification and supply of components. It will serve, in effect, as a "prototype" depot as the Air Force prepares to fit the *Bomarc* weapon into the continental defense. The first *Bomarcs* are scheduled to become operational within the next fiscal year, beginning July 1, 1958. Initial launching of the *Bomarc* prototype took place just five years ago this fall. A ramjet, the *Bomarc's* mission is to intercept fast bombers, but in Seattle recently Lt. Gen. C. S. Irvine, deputy chief of staff, materiel, said the Air Force might look at an advanced version for an anti-missile missile.

•

To keep pressurizing gas from mixing with liquid oxygen used as an oxidizer in liquid-propellant rocket engines, Rocketdyne has come up with a perforated inlet tube to slow down the nitrogen as it is diffused into the LOX system. Instead of mixing with the LOX, the nitrogen is forced to the top of the LOX tank before starting its pressurizing cycle. From 10 to 20 times less dilution of the LOX takes place with the new inlet tube, and this may increase performance up to 30 per cent for a long-range missile.



•

Lockheed picked Starline Way as the name for a street to be cut through the Sunnyvale missile plant site because it suggests the company's long line of star-named aircraft, now followed by the *Polaris* missile . . . Transistor business now about $30 million a year, is expected to reach $150 million a year in the next couple of years.

NEW MISSILE PRODUCTS

PRECISION SWITCH

Haydon Switch, Inc. has developed a unique type of miniature precision switch which is hermetically sealed, yet unaffected by high ambient pressures. The company claims that the actuation force remains constant even under atmospheric pressures as high as 180 psi. The switch is said to work equally well in a vacuum.

The design is applicable to miniature and subminiature switches of various electrical ratings. The company can also furnish the switch with a seal impervious to the deteriorating effects of immersion in corrosive liquids.

Circle No. 203 on Subscriber Service Card.

MICROSYN

Lear, Inc., is manufacturing a self-contained microsyn of approximately 1" diameter and 1" length, with a sensitivity of 500 millivolts per degree and with a threshold of 0.01 degree at 20V excitation. Linearity is within 0.5% to seven degrees. The subminiature microsyn weighs less than 1.2 oz.

Intended for use wherever there is need for accurate translation of angular displacement into electrical signals, the miniature units may be used in such

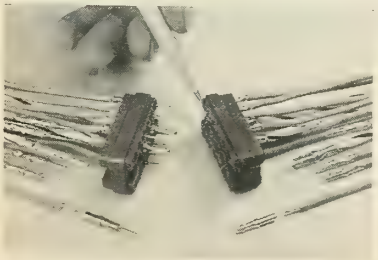
applications as position-indication of gyros, control follow-up devices, computation, motion and torque amplification, etc.

The company produces the microsyns with pigtail connectors or with color-coded teflon-insulated terminals. Excitation may be 20V, 400 cps or 25V 800 cos. The units use standard BuOrd mounting and have demonstrated resistance to the most severe environmental conditions.

Circle No. 214 on Subscriber Service Card.

ALUMINUM CASTINGS

New investment casting techniques in aluminum developed by Arwood Precision Casting Corp. are claimed to give higher guarantees of strength and ductility than have ever been possible in aluminum investment castings.



Castings produced by the "suparcast" method can be used wherever aircraft-quality castings are called for, and the user receives minimum guarantees of tensile strength, yield strength and elongation.

In high-stress areas of the casting, Arwood guarantees minimum tensile strength of 38,000 psi, minimum yield strength of 27,000 psi and elongation of 5%.

Circle No. 209 on Subscriber Service Card.

SOLDERLESS CONNECTOR

Solderless multi-lead plug-and-receptacle connectors designed to speed the wiring of electronic harnesses and achieve

greater dependability and versatility have been introduced by Burndy Corp.

Called the "Hyfen" the connector has two mating units, a plug and a receptacle. Instead of being soldered, pins and sockets are crimped to wire ends by single-stroke manual or high-speed automatic tools.

This method is said to be not only faster than soldering but also to make more reliable, more easily checked connections. Elimination of solder fluxes and dissimilar metals improves resistance to corrosion. A minimum number of contact points also reduces reliability problems.

Circle No. 202 on Subscriber Service Card.

SILICONE RUBBER

A new room-temperature vulcanizing silicone rubber has been introduced by Dow Corning Corp. Identified as Silastic RTV 501, it is intended for encapsulating electric and electronic parts and for general potting, sealing and caulking applications.

The material has a long shelf life in the unvulcanized state, is easy to handle and blend and retains its rubber-like properties over a temperature span of from –70 to as high as 500°F.

Silastic RTV 501 may be mechanically or manually mixed as long as three hours before application, in the proportion of 25 parts to one part Silastic Catalyst A by weight. Both ingredients have a viscosity of about 60,000 centistokes, or the consistency of a heavy fluid.

Vulcanization takes place within 24 hours at room temperature. The compound is completely stabilized after 48 to 72 hours. Moderate heating (up to 200°F) will accelerate curing in most cases.

Circle No. 204 on Subscriber Service Card.

ALL-PLASTIC GATE VALVE

The Vanton Pump & Equipment Corp. is making an all-plastic gate valve specifically designed to meet the problems of conveying corrosive and abrasive liquids in lines that cannot be chemically contaminated.

The product, called the "Flex-Plug" gate valve, combines both the straight-through flow, non-pressure drop characteristic of a gate valve and the throttling, flow-control feature of a globe valve, allowing for wide versatility of application. The valve is available in 1" and 2" sizes with screwed ends.

One of the design features of the valve is the resilient synthetic cap which can be removed quickly and replaced easily without removing from the line.

Wear of the resilient cap is at a minimum since the cap is flexible and seated on a swivel that is free to turn. It never reseats at the same place. In addition, because of the flexibility of the cap, the valve can handle slurries despite their abrasive action.

PRECISE CURRENT for your TESTING NEEDS!

VARIABLE FREQUENCY MOTOR GENERATOR SETS

ADJUST 360 to 440 CPS.

Generator mounted controls include reset buttons, limit switch. Motor and generator remain stationary. Vari-drive pulley adjustment controlled by small motor. Remote control panels available.

IMPORTANT DEVELOPMENTS AT JPL

Teamwork in Missile Development

The Jet Propulsion Laboratory provides a wide range of research and development activities. Projects include problems in the fields of Electronic, Mechanical, Aeronautical, Chemical and Metallurgical Engineering, Physics and Mathematics.

The fluid character of these activities provides a keen incentive to JPL engineers and scientists. These men are given wide latitude and unusual individual responsibility—at the same time working as a thoroughly integrated team on all aspects of entire missile systems rather than on certain highly specialized missile components.

JOB OPPORTUNITIES NOW IN THESE FIELDS . . .

SYSTEMS ANALYSIS • INERTIAL GUIDANCE • COMPUTER EQUIPMENT INSTRUMENTATION • TELEMETERING • FLUID MECHANICS • HEAT TRANSFER • AERODYNAMICS • APPLIED PHYSICS • PROPELLANTS AND MATERIALS RESEARCH

U. S. CITIZENSHIP REQUIRED

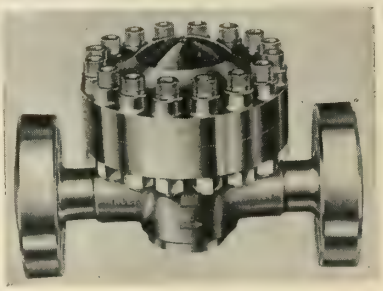
jpl

JET PROPULSION LABORATORY

A DIVISION OF CALIFORNIA INSTITUTE OF TECHNOLOGY

PASADENA • CALIFORNIA

The new Vanton Flex-Plug gate valve has a back-seating feature created by the pressure exerted by the seating of the flexible cap on the bottom face of the bonnet when the valve is fully open, thus relieving pressure of the packing.



The Flex-Plug gate valve is rated for 200 lbs. working pressure. The valve performs excellently under vacuum service. Research and field tests conducted by Vanton show that seating with a resilient surface against rigid plastic materials will hold a vacuum more efficiently than a metal-to-metal seal.

Circle No. 208 on Subscriber Service Card.

PRESSURE REGULATOR

A servo-dome pressure regulator has been introduced by Accessory Products Corp. which features exceptional accuracy in flow and/or pressure control.

Performance features include identical line and orifice sizes from ¼" to 3"; inlet pressures from 0 to 6000 psi; outlet

pressures from 0 to 5500 psi; zero leakage through positive shut-off; precision control accuracy and instantaneous response; and direct action which eliminates pilot control.

The valve handles a wide range of fluid media—air, gasses and liquids; a temperature range of –65°F to 250°F; internal or downstream sensing control; external or self-contained dome loading; burst pressure is four times rated pressure. Available in stainless steel, aluminum, alloy steel and bronze.

Circle No. 201 on Subscriber Service Card.

FLOWMETER

A new line of lightweight, turbine-type flowmeters with an accuracy of ½% has been developed by the commercial research division of the George L. Nankervis Co. The new flowmeters handle chemicals and other liquids over a wide range of temperature and pressure conditions.

Pressures up to 5000 psi are easily accommodated at temperatures ranging from –80° to 1000°F, viscosity permitting. Designated as the Cox Type 20, the new instruments are available in stainless steel or aluminum.

Accuracy of the new flowmeters is guaranteed to be ±½% of any reading over the 10:1 range of the instrument. Repeatability is ±.1 of 1%.

The flowmeter consists of a stainless steel (or aluminum) housing, a precision turbine wheel suspended in the housing, two flow straightening assemblies and a magnetic pickup coil. It can be calibrated either in gallons per minute or pounds per hour.

A significant feature of the new instruments is the fact that they can be easily disassembled for cleaning and servicing and reassembled without affecting

The Bell XH-40 turbine-powered 'copter . . . the Army's frontline workhorse of tomorrow

DISTINGUISHED PERFORMANCE . . . PLUS ECONOMY!

In designing rotor blades for the XH-40, the Army's most advanced utility helicopter, Bell Helicopter engineers were seeking a structural design that would combine outstanding performance with bedrock fabrication economy.

The solution? A uniquely different kind of rotor blade laminated of multiple layers of thin-gage, contoured aluminum sheets, bonded into an homogeneous structure with a high performance, high peel strength structural adhesive. This structure offers a host of performance and fabrication advantages . . . outstanding aerodynamic smoothness, low maintenance, excellent sealing qualities, high corrosion resistance, plus complete absence of assembly distortion. Furthermore, by completely eliminating stress concentrations, the bonded structure takes full advantage of the optimum fatigue life of the blade configuration.

Best of all, the bonded blade design has resulted in a dollar savings of 40 percent as compared with a conventional tapered forging design.

The adhesive used to accomplish the unusually large area bonding required in the fabrication of these laminated blades? A Narmco product, naturally . . . high peel strength, high fatigue resistant Metlbond 4021®. . . one of a great family of sandwich and metal-to-metal adhesives designed specifically to accomplish the toughest jobs in aircraft and missile design.

Cutaway cross-section of inboard half of the XH-40 rotor blade showing how the extrusions, machined parts, and contoured aluminum sheets are bonded with Narmco Metlbond 4021.

U. S. Army Photo

Experimental rocket being launched from tower at DOFL's Maryland test facility.

ELECTRONIC AMMUNITION THAT "THINKS" IS DEVELOPED AT ARMY'S DIAMOND ORDNANCE FUZE LABORATORIES

Since 1940, scientists and engineers at Diamond Ordnance Fuze Laboratories, with their industrial contractor counterparts, have made important contributions to electronic ordnance. These include the proximity fuze, greatly improved fuzes for antitank and other special ammunition, and, more recently, fuzing systems for guided missiles. Other basic results of DOFL's research and development teams are new electronic systems which increase the accuracy of measurement of distance, velocity and direction, new electronic and mechanical control systems, and new and radical components and materials. DOFL's main laboratory is in Washington, D. C., and it maintains an extensive test facility at Blossom Point, Maryland. Over 1400 scientists, engineers, technicians, and supporting personnel work in these centers.

Electronic ordnance was born in World War II. Ammunition of this type, a DOFL specialty, senses the presence, distance, and direction of a target and causes the warhead to function at the instant when it will inflict the most damage. Electronic control can be compared to having a sharpshooter in every piece of ammunition. The accurate effect is devastating.

Many advances in ruggedness and miniaturization, pioneered by DOFL, are contributing significantly to peacetime technology. Typical industrial products which sprang from ordnance programs are printed electronic circuits, tough and tiny electronic tubes, and rigid mounting of components in solid plastic blocks. These valuable by-products have contributed heavily to the ability of DOFL's industrial teammates to design safer, smaller, and better components.

This is one of a series of ads on the technical activities of the Department of Defense.

linearity. Twelve sizes of flowmeters, with capacities ranging from .25 to 125 gallons per minute, are available.

Circle No. 212 on Subscriber Service Card.

FREQUENCY CONVERTER

Designed for application with guidance systems and in telemetering functions, a new transistorized frequency converter is being marketed by the Aeronautical Division of Robertshaw-Fulton Controls Co.

A substantial size-weight reduction is said to have been achieved over previously available rotary electro-mechanical frequency converters. Use of transistorized circuitry has reduced weight and overall size by approximately 60 per cent, and brought about minimum maintenance conditions.

Circle No. 215 on Subscriber Service Card.

HYDRAULIC PUMP

A large capacity variable delivery hydraulic pump has been developed by the Stratopower Division of The New York Air Brake Co. The pump, designated as the STRATOPOWER 64W1000, is claimed to have several design advantages over existing pumps on the market, including high horsepower per lb. ratio (2.8 hp/lb.), a light, compact package delivering over 50 hydraulic horsepower in an envelope 9⅛ x 6¼ inches weighing approximately 19 pounds, and exceptional control stability.

Other features include high overall efficiency of 90 per cent or more, low inlet pressurization of under 50 psi at full speed, self-aligning rotating members and exceptionally low pulsation and oversurge characteristics.

Circle No. 205 on Subscriber Service Card.

MAGNETIC HEAD

A 7-channel magnetic tape recording head developed by Data Storage Devices Co. can be directly connected to thermocouples to record without the use of amplifiers, using only 20 microwatts. The complete system is carried aboard a missile and the head has been designed to withstand high shock and vibration forces as well as high temperature and thermal shock.

Other features of the small, lightweight, aluminum head include gap alignment scatter under 1/10 MIL, mounting base machined to within 90° ±15 seconds of the gap line and tape guides integral with the head.

Circle No. 216 on Subscriber Service Card.

TAPERED ORIFICE VALVE

A valve expected to replace needle valves in nearly all applications has been introduced by General-American Valve Co. The tapered orifice valve features a new concept of flow control and will pass foreign particles up to twenty times larger than comparable needle valves.

By moving a plug with a tapered slot into an out of the circular valve opening, the flow of fluid or gas is controlled by the area of the tapered slot at the head of the opening. A circular sealing ring eliminates by-pass.

Principal advantages of the new type valve are its high accuracy in flow control, infinitely variable control, non-clog-

LIQUID OXYGEN AND NITROGEN TRANSPORT UNITS

Hofman 3000 Gallon Trailer

Built to A.S.M.E. and I.C.C. specifications in sizes from 500 to 3500 gallons. Efficient performance is shown in this Hofman powder in vacuum insulated equipment. CHIEF OF DESIGN

This internationally known aeronautical equipment engineering and manufacturing firm is looking for a "balanced", premium quality Chief of Design. The salary, very high, matches the requirements.

Must have proven creative design ability. Must be able to lead, and inspire, two groups . . . more than 100 engineers and more than 150 detail and layout draftsmen. Offer constructive criticism and evaluate their efforts. An able assistant will relieve him of routine duties.

Naturally, he must have a broad knowledge of manufacturing techniques for a variety of mechanical and hydraulic devices. He must understand cost factors, both from a development viewpoint and in-operation amortization viewpoint. He must keep current on not only all skills and techniques employed by his company, but throughout the industry.

In summary: our Chief of Design will constantly judge designs and drawings for functionalism, sound integration into existing components, and legitimacy of production from a profit perspective. He must maintain and guide technical groups to achieve such output economically.

Reply to: Mr. Robert F. Webb, 250 Park Square Building, Boston 16, Massachusetts

LIQUID SPRINGS

A miniature spring using liquid compressibility has been developed by Taylor Devices Inc.

The ½" diameter, self-contained liquid spring developes 800 lbs. force at ¼" stroke with an 80 lb. preload and is only 2" long plus ⅜" mounting stud. By the use of an internal hydraulic levering principle, the liquid spring produces up to 20 times the force of a standard coil spring of the same diameter and length. Liquid springs and Spring Shoks up to 50,000 lbs. force are available from the company.

Taylor's liquid springs, with standard ⅜-24 mounting thread, are preloaded and completely self-contained, eliminating stripper bolts, washers and mechanical springs.

"Old Faithful"

Rocket motors powered by Phillips solid propellants have set new standards of confidence in programmed performance. Scheduled firings are made on schedule . . . to the second! The reliability of Phillips solid propellants in jet-assist take-off applications is extremely high.

Such outstanding uniformity and dependability are due to the design simplicity of Phillips solid propellant systems. Because they require no pumps, valves, or internal controls, the possibility of mechanical failure in Phillips solid propellant rockets has been substantially eliminated. Process and quality controls assure in advance that each production unit has the desired ballistic characteristics.

Recent technical breakthroughs achieved by Phillips extend the limits of solid rocket thrust and duration with less weight and greater efficiency. Furthermore, Phillips solid propellants are easy and safe to handle or store . . . and the cost advantage is considerable.

Check with Phillips for latest developments in this field before your designs are committed.

K-FACTOR TESTER

Specific thermal conductivity of materials is measured with a K-factor tester developed by Tatnall Measuring Systems Co. The device consists of a portable hot plate unit, a cold bath and a relay rack. The hot plate unit is a seven-layer sandwich of plates held together by spring-loaded bolts. The unit and electrical connections are enclosed in a bag of thin plastic. The two outside plates are metal coolant plates and the three central members form the heating part of the apparatus. Specimens up to 1.25" thick are held between the coolant plates and the heating section. Special models operating at temperatures up to 600°F are available. The cold bath comes in three models which operate from room temperature down to —100°F. Various models use water, water and glycol, or alcohol and solid CO_2 for coolant, depending on the operating temperature required. Measurements take from two to six hours, depending on specimens, and readings may be taken from the recorder on the relay rack or from a potentiometer.

Circle No. 208 on Subscriber Service Card.

ROCKET IGNITER TESTER

Model 101-5A igniter circuit tester has been approved by the Army Field Services Division and the Safety Engineer at the Office of Chief of Ordnance. Featuring very low output for maximum safety, the 101-5A is used for preflight testing or for routine quality control igniter inspection.

Unit has .005 amp. output and this is achieved at net loss in accuracy which is —.01 ohm in the 0 to 5 ohm range, and —.02 ohm in the 5 to 30 ohm range. Instrument is suited for field use because of its portability, fast operation, weatherproof construction, one-year battery life, and 4-place digital readout.

The tester is manufactured by Allegany Instrument Co., Inc.

Circle No. 258 on Subscriber Service Card.

CO-POLYMER SEALING COMPOUND

Stillman Rubber Co. has developed a compound said to have exceptional oil and fuel resistance at extreme temperatures for use in bonding and sealing operations. Designated SR 251-70, the compound is available for prototype and small production orders.

The compound may be bonded to aluminum and many other metals, making it suitable for poppet applications at temperatures as low as —65°F. For dynamic sealing, minimum recommended temperatures range from 400° to 500°F, depending on duration of heating. The material is suitable for both dynamic and static sealing.

Circle No. 209 on Subscriber Service Card.

CHECK VALVE

High pressure valve operating at 5000 psi (7500 psi proof, 12,500 burst) and from —320°F to 450°F in fuming nitric acid, LOX, liquid nitrogen, propylnitrate, anhydrous ammonia, helium, hydraulic fluids and other liquids and gases. Construction is of Carpenter #20 steel with body poppet and stops, Hayne's alloy #25 steel spring, entrapped Teflon seat; available from ¼" to 1". Cracking pressure is ¼ psi and a variety of port sizes are available.

Circle No. 217 on Subscriber Service Card.

LIQUID DENSITY MEASUREMENT

Precision Thermometer and Instrument Co. has developed a precision device for measuring liquid density of continuously flowing process liquid. The device has zero-set and temperature adjustments for original calibration under working conditions and to provide temperature-corrected specific gravity readings. Readings can be made directly without reference to charts or graphs. The instrument is for use at temperatures to 220°C, and is available in ranges from .01 to .50 specific gravity. It can be used at pressures up to 125 psi., and is equipped with standard connections.

Circle No. 221 on Subscriber Service Card.

PRECISION AIR GAGE

Precision air gages to check gimbal alignment and concentricity are being produced by Federal Products Corp. The three readings, gimbal alignment with each pivot with the centerline of the gimbal and concentricity of one pivot with the other, are indicated simultaneously on dials of a triple-unit air gage. Dials are graduated to 20 millionths of an inch.

The company says that gages have been developed to handle gimbals up to two feet or more in diameter, and the techniques can also be applied to the accurate positioning of parts when machining to tight tolerances.

Circle No. 222 on Subscriber Service Card.

RADOME CERAMICS

Kearfott Co. has announced the availability of high-purity, aluminum oxide ceramics for use in radome construction. The material is said to have unique dielectric properties in the microwave region. At 50kMc its loss factor is only 0.000093; X-band and Ku-band loss factors vary from 0.0017 at room temperature to 0.00017 at 1000°F. Most significantly, its dielectric constant of 9.38 ± 1% remains stable over the entire temperature range up to 1000°F. The material has a frequency loss at high temperatures 50 times smaller, and at 10kMc the loss is 20 times smaller, than commercial high alumina materials.

Circle No. 223 on Subscriber Service Card.

BALANCED MIXER

A series of millimeter wave balanced mixers (Series MA-1026) has been developed by Microwave Associates, Inc. The series is designed for use with RG-96/U waveguide transmission systems and when used with matched pairs of 1N53 or 1N53A coaxial mixer crystals, the units provide high local oscillator noise suppression in Ka-band radar receivers over the 34-36 KMC/s range. The VSWR is 1.3 maximum, balance is ½ db, cross talk is 20 db minimum, and output capacity is 3 uuf, nominal.

Circle No. 224 on Subscriber Service Card.

PRESSURE REGULATOR

A hand-adjustable pressure regulator and relief valve for accurately controlling gases such as helium, nitrogen and compressed air, under pressures up to 3000 psi has been developed by Futurecraft Corp. The regulator, termed the Hi/Lo handloader, is of the zero-bleed internal venting type with hand-adjustments of the control knob regulating pressure and providing pressure-relief over the entire 0-3000 psi range.

missile miscellany

It's spelled S-P-U-T-N-I-K; pronounced SPOOTNIK; means "fellow traveler." It also means that we, as a nation, have goofed badly. We insisted Vanguard had no military or political significance—wrong on both counts. We separated Project Vanguard from all other (military) projects—and isolated it from all other knowhow and proposals. We stubbornly refused to consider at least two other vehicles which could have placed a satellite (of much political and some scientific significance) in an orbit—the X-17, 18 months ago; Jupiter-C, at least a year ago. Either could have and still can get an 18-to-20-pound beeper up there. Army not only has Jupiter-C's ready to go but satellites as well.

And just in case you missed them, here are some of the bitter quips that ran through Washington in the immediate P.S. (post-Sputnik) days: A suggested sign over Vanguard Chief Hagen's door: "Washington slipped here." Sputnik decoded #1: "I like Ike. I like Ike. I like Ike. I . . ." And as it goes over Washington #2: "Beep, beep, beep—ha ha—beep, beep, beep—ha ha—." Real name for Vanguard—Rearguard; or Offguard . . .

There's renewed talk in Washington of a preventive war (by the same old spielers) should Russia conclusively demonstrate she's too far ahead of us technologically. And a counter-fear that Russia, or more specifically Khrushchev, might try the same just to keep himself in power. Everybody loses either way.

Chess-playing Russia aimed to sputnik on September 17 in honor of space flight pioneer Tsiolkovsky and missed by a mere 17 days. Then before the Reds had lost their advantage, Sputnik became Sputniki. This is pawn position. Next the knights, castles and bishops will move out onto the board, and finally the queen—man into space. Placing half a ton of satellite into an orbit means Russia has the rockets to do this now. Recovery of the dog alive will mean the Reds also have the other necessary knowhow. The West faces a grave and deepening danger.

After the recent AF press conference announcing the results of Project Far Side, the correspondent for one of the nation's leading newspapers remarked bitterly, "My paper detests liars." So does this page. So it aims to put the record straight: Before Sputnik, there were two official attempts to kill Far Side—once last spring when ARDC tried to shift it over to its Cambridge research division or have it eliminated, and once this summer when Asst. Secretary of AF Horner tried to kill it, saying, "AF has no business going to the moon." In both instances Air Force Office of Scientific Research fought hard and won. Second try though (when AF gave in), it categorically refused to grant more money. Thus, taxpayer paid $750,000; Aeronutronics Systems, Inc., put up $400,000 of its own funds. With Sputnik, however, top AF types hailed this as greatest thing ever; now claim full credit for dreaming it up, pushing it through and being so well prepared to hold up our country's honor. And put such pressure on Eniwetok launching teams to hurry up that three shots launched in marginal weather were failures. Credit where credit is due: To Dr. Morton Alperin, Col. Wm. O. Davis, Thomas Wilcox, Dr. S. Fred Singer, Dr. Harold Wooster, Mel White and the men of Aeronutronics

and to the Army for having low-cost off-the-shelf rockets available. In August this page wrote: "This page figures the future's for those who stick to the facts; that for those who would cite fact and fiction as one, tomorrow will be rough; end early. And speaking of facts, like dates, those who have reason to fear the first shake should beware the Ides of October."

It's still true after Sputnik as well as before . . . Let's cut the politics; let's quit trying to cover up; let's use the past solely as a classroom; and get on with the job—before the Russians atomize or Siberianize us.

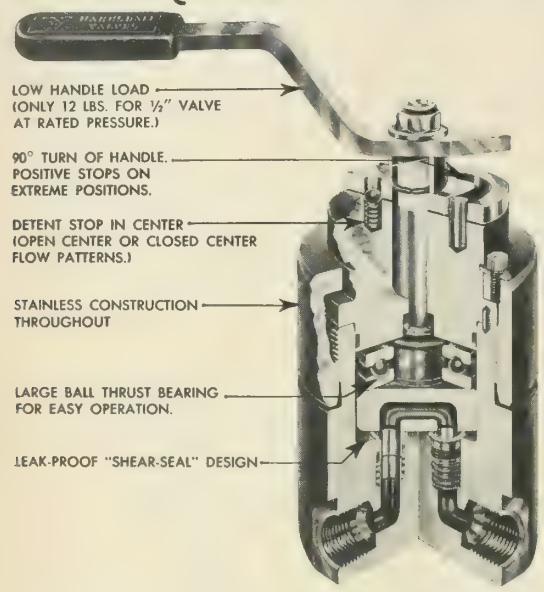
Reports of Soviet 820,000-pound-thrust rocket motor may mean they're well along with T-4, their boost-glide skip bomber . . . Reds also claim to have solved manned re-entry problems with parachutes . . . Feat of atomic-powered Nautilus submarine going 1000 miles under arctic ice pack could have connection with U.S. Navy claims that fleet ballistic missiles can be fired from under arctic ice—by first melting a hole in it.

Chicago University astronomer G. P. Kuiper, using self-designed infrared spectrometer, has decided Saturn's rings are made of snow; there's CO_2 in Martian atmosphere; some of Jupiter's moons also have snow . . . Temple University Research Institute is static-testing liquid rocket engines using 100% pure liquid ozone; also firing LOX with cyanogen to achieve 4800°K combustion temperatures . . . Ultrapure titanium, zirconium, chromium, hafnium, columbium, and vanadium can be made by aluminum reduction of their oxides . . . Gold-bonded transistors show improved alpha cut-off frequencies . . . AF has run up against a stone wall in trying to find name for radar-jammer-jammer.

Anent Pentagon flip-face on giving out missile firing information, this page was warned: They can tell just as little of the truth with a flood of claims and statements as they can by keeping mum. Step's for the good, though.

There's a vernier solid-propellant engine now under development for Jupiter at ABMA-Redstone. It mounts behind nose cone with a break-away nozzle and has some connection with improved terminal guidance, hiked range or both.

The other night this page listened with respect to a dedicated space flight man who claimed our only hope of getting really ahead of Russia in the current technological race was to cut through—to go directly to the step after next and to work toward putting man into space for 48 hours and safely recovering him. There are some people in qualified positions who think that, with the right management, we could do that within 30 months, and it need not cost many billions of dollars —maybe under $200 million, in fact.



Also a suggestion that the U.S. would do well to establish something outside the military services roughly equivalent to Russia's very active Commission on Interplanetary Travel. And a hope from the people in this country who are worried that Sputnik may have been like an . . .

10,000 P.S.I.

4 WAY VALVE

FOR LIQUIDS OR GASES

This new four-way valve series comes in pipe sizes from ¼ to 1 inch, but may be obtained with tube, AND 10050, or any preferred special high pressure connection. It will withstand surges of up to 15,000 P.S.I. without damage to the valve's sealing qualities. It is designed for a burst pressure of 30,000 P.S.I.

No port to port leakage occurs in the detented positions because of the exclusive "Shear-Seal" design.

Long, maintenance-free service is assured because the optically flat metal to metal sealing surfaces of the sealing rings and mating rotor faces are protected by staying in constant intimate contact; flow is always through the center of the "Shear-Seal", never across sealing surfaces (as in conventional valve design). Sealing qualities actually improve as the self aligning "Shear-Seals" lap themselves to a more perfect fit with each valve operation.

Of course, there is no external shaft leakage, because the pressure is confined to the flow passages.

This highly successful principle of extreme pressure control is fully described in "Shear-Seal" bulletin BVM-2.

SCIENTISTS AND ENGINEERS:

Lockheed Missile Systems offers staff positions at Palo Alto and Sunnyvale, California

(Both facilities are within 38 miles of San Francisco)

Weapon systems management programs at Lockheed Missile Systems call for achievement of a high order in these fields. Assignments are on the Polaris Intermediate Range Ballistic Missile program and other extremely important activities.

Aerodynamics

Theoretical and experimental investigations of the aerodynamic characteristics of missiles at Mach numbers through the hypersonic range; optimization of controlled missile performance; specification and supervision of experimental aerodynamic investigations required to verify and improve missile and weapon system design; analysis and interpretation of aerodynamic flight test data.

Flight Dynamics

Analysis of missile dynamic motion and establishment of stability and control systems criteria for trajectories with 3 or more degrees of freedom; development of techniques for the analysis and interpretation of flight dynamics test data at hypersonic speeds; study of special dynamics problems arising during preliminary design and development of missile systems.

Thermodynamics

Boundary layer and heat transfer analysis in hypersonic flow fields such as pressure gradient- and real-gas effects; analysis of thermodynamic performance of missiles in continuum flow, slip flow and free-molecular flow; calculation of transient structural and equipment temperatures resulting from aerodynamic heating and radiation; specification of ground tests and flight tests required to verify and improve thermodynamic design of missile and weapon systems; analysis and interpretation of thermodynamic ground test and flight test data.

Engineers and scientists are invited to address inquiries to: Research and Development Staff, Palo Alto 7, Calif.

Missile Business

By Seabrook Hull

THE ADMINISTRATION CAN DO NOTHING of a major nature for weeks, maybe months, to try and counteract *Sputniki*. A combination of the statutory national debt limit plus the expenditure accounting system now employed mean that there is neither money nor obligational authority for moving quickly. The Administration is hog-tied until either Congress raises the debt limit, the expenditure accounting system is dropped or tax revenues as a result of 1957 earnings start coming in. This last will result in an easing of the situation by about mid-January, 1958.

WATCH CONGRESS FOR THE TIP-OFF on the how's and when's of a major reorganization of our missile effort. Almost to a man, the House and Senate are stung (a) by Russia's technological surge ahead and (b) the Administration's efforts to laugh it off. There has been a basic loss of confidence by the American people which Congress feels probably more than the White House.

Any precise forecast of just what the next 12 months hold for our missile, rocket and space flight effort obviously isn't possible. However, you can get a pretty good idea by running down the list of probables, based on public statements by the Congressmen and on private conversations by m/r editors. Two basic things are certain: The final result will be a major reorientation of our whole space flight and missile program. And, it will mean more missile money for you—or less.

HERE'S HOW CAPITOL HILL THINKING IS GOING—a list of the actions that will be considered, some of which you can count on being adopted:

A NATIONAL ADVISORY COMMITTEE FOR ASTRONAUTICS—a wholly independent, nonmilitary agency drawing on the best from all sources to make U.S. space flight effort a No. 1 priority project, like Russia's Commission for Interplanetary Travel. Russian *Sputniki* are Russian—not Army, Navy or Air Force—satellites.

A JOINT CONGRESSIONAL COMMITTEE FOR ASTRONAUTICS, similar to that now in being for atomic energy, to keep constant watch on our progress in space fight.

A DEPARTMENT OF SCIENCE with a scientist in the Cabinet—to assure optimum efficiency in fighting Russia in the technological struggle.

A COMPLETE SERIES OF INVESTIGATIONS by several major Congressional committees, such as Appropriations, Armed Services, Government Operations and Atomic Energy. These will be aimed not so much at fixing the blame for our current lagging position as they will be aimed at finding out why and what can be done now to remedy the situation. In these hearings Congress will rely heavily on people in Government.

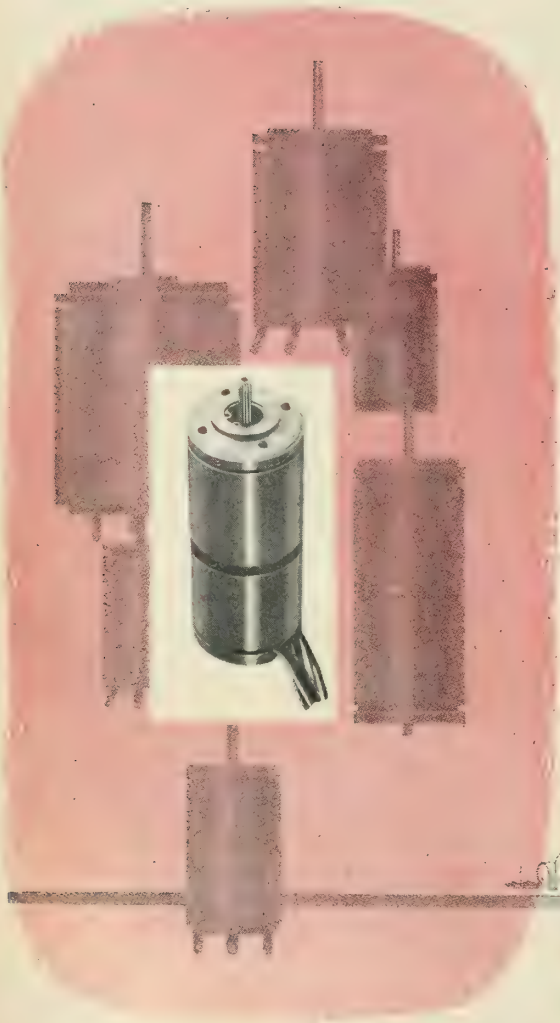
NO CUTBACK NOW ON MANNED AIRCRAFT until new weapons are really available, but maybe a major effort to jump way ahead with such projects as boost-glide skip bombers, manned satellites, a true space force, man on the moon, etc. This means a budget increase and a major reshuffling of current emphasis.

OPENING THE FLOODGATES OF MONEY is definitely not in the cards. Selectivity is a must. Congress will insist on it, being pretty much convinced the fault was not how much money but how it was spent.

A MAJOR LOOK AT EDUCATION is also certain. In this instance, *Sputnik* may provide the incentive to really do something about increasing teachers' pay and bringing school capacity up to population. Also, there will will be a real effort to revamp what is taught, when and how. This means more emphasis on mathematics and the physical sciences in grade and high schools. It may also mean a Federally supported system of scholarships to assure that those young people with promise get the chance to go to college.

MORE PAY AND RECOGNITION FOR GOVERNMENT SCIENTISTS is a good bet. Also, Congress may suggest that industry develop some means of rewarding its technological manpower other than by promoting them into administrative jobs.

EDISON MINIATURE -- HI-TEMP



servo systems and components

The Edison Instrument Division is now offering design engineers an extensive line of miniature and subminiature Hi-Temp Servos and Servo Components . . . in addition to a complete facility for custom designed units and servo sub-systems.

Edison's Size 11 Motor Damping Generator for example, was built to such precise tolerances that a leading systems manufacturer was able to make this particular unit do double duty as a tachometer generator. This miniature unit's fast response and large output signal makes it ideal for applications where weight, size and high performance are prime requisites.

Precision production and rigid quality control inspection have made these "customized" components possible. In addition to these special units, Edison also manufactures an extensive line of standard servo motor and servo motor-generator combinations from size 8 - up, a quality group of synchros, and custom-engineered magnetic heads for flight and ground-based analog computers.

For information about Edison precision Servos and Servo Components, write for Catalog No. 3044 . . . your copy is reserved.

EDISON SERVO MOTOR DAMPING GENERATOR

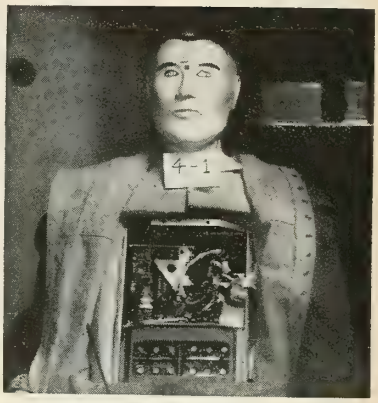
special features

Will commercial TV networks interfere with missile technology?

Limited space in the radio spectrum allocated for radio telemetry is creating a serious bottleneck in missile performance data-gathering. AAP Electronics Editor Henry Steier discusses the importance of telemetry in the transition to unmanned flight (page 149).

What are the applications of electronic components miniaturization in the missile system?

In missile evaluation the Micromation (miniaturization) concept is being applied to computing, controlling and indicating functions of complex missile systems. Sidney Herman of Waldorf Instrument Co. introduces typical applications of the Micromation system (page 154).



Is it necessary for specialized precision instrumentation to be confronted with continuing obsolescence?

Walter H. East, Vice President of Electro Instruments, Inc., presents one solution to the problem of obsolescence. An integrated modular instrument design is capable of combining and integrating with other instruments to form complete data-handling and automation systems (page 160).

How can missile training costs be reduced?

Expenses have been greatly reduced in the training of guided missile operators by use of electronic devices instead of actual missiles. An m/e editor, Frank McGuire, describes the system produced by Giravions Dorand, a French firm (page 166).

cover picture:

Hurricane Sam, an anthropomorphic dummy, is the star performer at the SMART test track located at Hurricane Mesa, Utah. Base cost of Sam is $3000 and when fully instrumented costs $10,000. Tests with Sam have been conducted to investigate the F-94C ejection seat at a speed of 600 mph. The dummy was ejected about 11,000 feet down the track from the breech end. However, Sam did not separate from his seat and, as a consequence, became a battered dummy on the mesa slope below the muzzle end of the track. Sam's instrumentation was designed to withstand the tremendous accelerations and impacts encountered.

Unhampered by traditional thinking, TELECHROME engineers have developed an entirely new concept in telemetering equipment. Today's new environmental conditions and distances for missiles require new designs. TELECHROME units are unequalled in compactness, ruggedness* and dependability. Because of their superior qualities these highly efficient units are replacing equipment of other manufacture.

washington briefs

BATTELLE MEMORIAL INSTITUTE in Washington says it is studying the effects of radiation damage to semiconductors under an ARDC contract. Details of the mechanism of radiation damage will aid in selecting semiconductor materials for use where radiation is a potential hazard.

NATIONAL BUREAU OF STANDARDS here is conducting research on the chemical and electrical properties of solid wax electrolyte batteries. A new field of battery research, the investigation is expected to help in understanding the phenomena that takes place in wax electrolytes subjected to electrical fields. It may also show better methods of fabricating such batteries.

TWO NEW ELECTRONIC STANDARDS for the electronics industry have been published by EIA in Washington. They concern fixed film resistors (high stability) and power filter inductors for electronic equipment.

ATOMIC ENERGY COMMISSION is asking for bids from qualified companies for preliminary studies on a compact nuclear reactor system for military use. The Department of Defense wants a mobile powerplant with moderate power rating (up to 2000 kilowatts net electric output), extreme compactness and low weight.

AIR MATERIEL COMMAND'S Brigadier General Ben I. Funk has told the West Coast Electronics Manufacturers Association that almost every subsystem of the ballistic missile is almost totally dependent on the successful application of some type of electronic hardware. In view of this, he added, "it becomes apparent that we not only want your participation in our program, but that we need it badly."

RELIABILITY AND QUALITY CONTROL SYMPOSIUM will be held in Washington from January 6 to 8, at the Statler. Papers will be presented by more than 40 industry authors and those from the military, government and research institutions. Open panel discussion on reliability definitions will be moderated by C. M. Ryerson of RCA.

RADIO ASTRONOMY has given rise to a new method of using solid-state amplifiers which give 20- to 30-db improvement over noise problems. The technique is applicable from 1500 mc to the infrared portions of the spectrum.

WESTINGHOUSE RESEARCH LABORATORY has developed a magnetic steel which allows magnetism to turn around corners, and which promises to improve the performance and simplify the construction of electrical apparatus. Named Cubex Steel, the material is a major scientific breakthrough for the electrical industry and is technically known as "cube-oriented silicon-iron." Crucial characteristic of the steel is its unusual ability to be magnetized easily in four directions, eliminating the need for piecing a magnetic core together.

TESTERS FOR ELECTRONIC TESTERS have been developed for ARDC to calibrate and adjust AF electronic equipment for maximum accuracy.

USAF IS HAVING A HARD TIME finding a term for the device to jam radar jammers. As in the anti-anti-missile-missile-missile (one that destroys anti-missile missiles), they are afraid it will be the start of a chain—such as counter-countermeasure device . . . and here we go again.

HOW BIG IS *SPUTNIK* I? Electronics experts are wondering. Andrew Ledwith, Smithsonian Astrophysical Observatory technician, figures that it is either 16.7, 33.4 or 66.8 inches in diameter. He bases his figures on the size of the antenna and the frequency it broadcasts on.

WHAT WILL "THE ENGINEER'S COMPUTER" DO FOR YOU?

The LITTON 20 DIGITAL DIFFERENTIAL ANALYZER is a uniquely personal mathematical tool – which you use yourself at your own desk. The remarkable insight you obtain with this accurate, versatile instrument is an experience reported again and again by mathematicians and engineers. *Insight into the problem* stems partly from your *own* programming, partly from the continuous rapport you have with the problem as the Litton 20 solves.

THE LITTON DDA plugs into any standard 110-volt outlet. You need only a few hours of coaching from us to grasp the programming for –

Solution of linear and non-linear differential equations including those containing transcendental functions.

Evaluation of definite integrals.

Solution of algebraic and differential equations in complex variables, including conformal mapping.

Simulation of non-linear dynamical systems.

Generation of any standard algebraic, trigonometric, or inverse trigonometric functions.

Trajectory problems, including generation of the standard atmosphere.

Aircraft stability problems.

Generation of the special functions of mathematical physics which can be expressed as solutions of differential equations. These include the Jacobi Elliptic Functions, Sturm-Liouville Equation, Hypergeometric Function and Legendre Functions.

Multiplication and division of variables.

Coordinate system transformations.

Performance of logical switching functions, such as introduction of step functions, ramp functions, limiting, and mode of operation switching.

CAPACITY: Model 20—20 Digital Integrators
Model 40—40 Digital Integrators

ACCURACY: Up to 1 part in 260,000 (to 5 decimals).

COST: $12,800 & $16,800.

ACCESSORY EQUIPMENT AVAILABLE: GRAPH PLOTTER GRAPH PLOTTER/FOLLOWER • PAPER TAPE PUNCH/READER • DIGITAL TO ANALOG CONVERTER

missile electronics news

Raytheon Occupies New Facilities

Raytheon Manufacturing Co.'s missile systems division headquarters will move into a new 40,000-square-foot office and laboratory building in November. Completely air-conditioned, the building will be located on a tract of slightly more than four acres.

Raytheon is prime contractor with complete systems responsibility for both the Army *Hawk* and the Navy *Sparrow* III missiles. The division has plants or laboratories in Bedford, Lowell and Andover, Mass., and Bristol, Tenn. It also maintains flight test facilities at Oxnard, Calif., adjacent to the Naval Air Missile Test Center, Point Mugu, Calif., and at the Army's White Sands Proving Ground, N. M.

The division employs more than 6800 employees and occupies about one-third the total manufacturing space of the company.

Army Tracks Satellite With Direction Finder

The Army's newest high-power direction finder has been brought to bear on *Sputnik,* assisting in tracking its orbit as far as half way around the globe.

The high-precision radio sentinel at the U.S. Army Signal Engineering Laboratories, Fort Monmouth, N.J., is one of the more recent additions to the military electronics arsenal and is capable of pinpointing signals in any part of the earth, and far out into space.

Alerted shortly after the satellite's launching, the direction finder has sighted and followed the sphere by radio almost every time it circled the earth.

The high-precision equipment, designed to pinpoint enemy radios in combat, is in operation 24 hours a day scanning the skies for the satellite's faint radio beep. On contact, a propeller-like pattern flashes on the electronic viewing screen to give operators a direct and continuous angular bearing on the sphere.

At the same time the Army Signal Corps' latest high-power combat receivers were in operation and picked up the satellite's signal during 50 consecutive revolutions, intercepting it both directly and via the long path around the world, spanning a distance up to 24,000 miles.

Electronic Engineering Co. Leaves Canaveral

The Electronic Engineering Company of California has closed its Florida division offices and transferred the research and development operations at Cape Canaveral Missile Test Center to the company's main laboratory in Santa Ana, Calif.

Electronic Engineering designed and developed missile-range instrumentation equipment for the base, including the timing system, several digital data-transmission systems, radar installations, plotting-board instrumentation and other special work. Total cost of the work was in excess of $4 million.

The company first established a Florida division during the early development of Cape Canaveral as a test base in 1950.

Transfer of operations resulted from the reduction in field engineering needed to integrate new equipment into the instrumentation system as the field office at Patrick Air Force Base is no longer required. Operation of the test range is under the joint management of RCA and Pan American Airways.

Hallamore to Produce TV For Remote Operations

Contracts totaling nearly $300,000 for closed-circuit TV systems to monitor rocket engine and missile testing have been awarded the Hallamore Electronics Co.

The systems, two of the largest ever developed for this purpose, are being installed for the Army's guided missile center in Huntsville, Ala., and The Martin Co.'s *Titan* ICBM program in Denver.

Under the two orders, Hallamore will provide a total of 46 systems, each consisting of a receiver, a single multiwire connecting cable, and a camera capable of withstanding the white-hot exhaust blast of rockets. Each system affords intercommunication between receiver and camera locations as well as remote control of camera lens position and pan and tilt action.

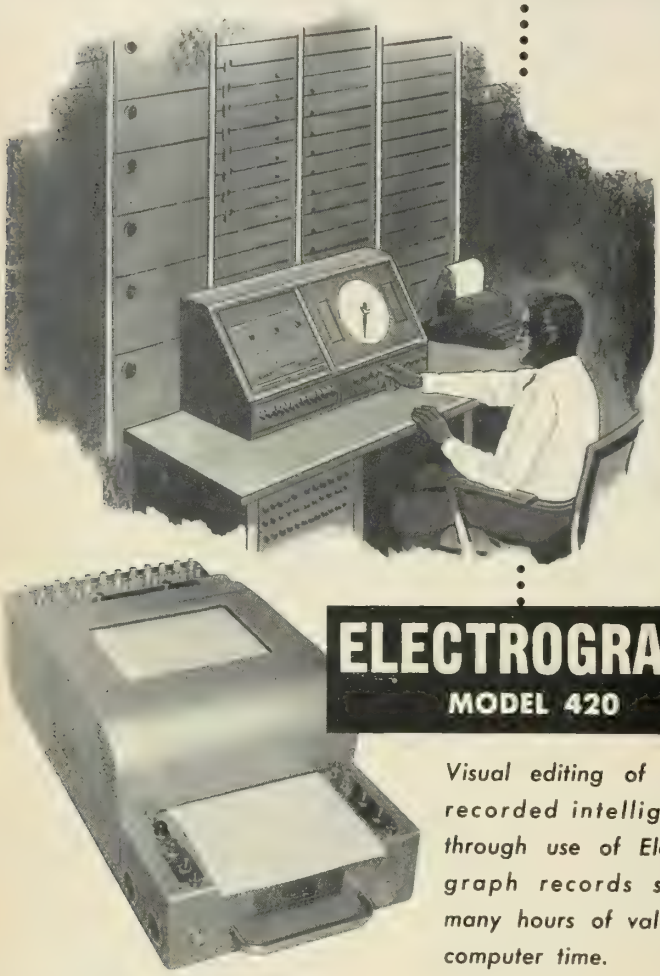
Scheduled for completion early in 1958, the 24-system installation for The Martin Co. was described as one of the largest in the nation. The Army Ballistic Missile Agency installation consists of 22 systems.

Tele-dynamics Completes Philadelphia Plant

Tele-dynamics, Inc., manufacturer of telemetry systems, has completed occupation of a new plant in Philadelphia, Penna. The plant contains advanced facilities for research, development engineering and production of electronics equipment. It occupies about 100,000 sq. feet.

Aircraft Firms Pay for Missiles

Aircraft companies working on ballistic missiles are contributing a large part of the cost of the programs, according to Orval R. Cook, president of Aircraft Industries Association. In making the statement, Cook cited figures furnished by Brig. Gen. Ben I. Funk, ballistic missiles manager for AMC.



From the time that acceleration of the ICBM and IRBM programs was ordered in 1954 until July 1957, the government invested nearly $200 million in new facilities to build the weapons, according to Funk. During the same period, the contractors on on the *Atlas, Titan* and *Thor* programs provided about $100 million of their own funds for the same purpose.

Bendix Computer Division Opens Office in New York

Bendix Aviation Corp.'s computer division has opened a new district office to handle sales, service and applications of its general-purpose electronic computer and accessories in the New York area.

The company pointed out that Bendix computer division now ranks fourth in size among electronic computer manufacturers.

computer time saved with

ELECTROGRAPH
MODEL 420

Visual editing of tape-recorded intelligence through use of Electrograph records saves many hours of valuable computer time.

24-channel Electrophotographic Recording Oscillograph

Now you can edit telemetered tape-recorded information and select the data to be fed into the data reduction computer. As many as 24 channels of tape signals connected to the Electrograph galvanometers through appropriate discriminators may be recorded simultaneously. The analog record is instantly readable as it is discharged from the recorder. Proper keying of the permanent record to the tape permits visual selection of the data to be placed into the computer.

Records produced by the Electrograph are permanent, requiring no further processing, and may be stored indefinitely without loss of trace definition.

For further information regarding the Electrograph, you are invited to write, wire or call for bulletin CGC-311.

Century Electronics & Instruments, Inc.

1333 No. Utica, Tulsa, Oklahoma

Largest Analog Computer Installed at Convair

The largest direct analog computer ever built is now being installed in facilities of the Convair Division of General Dynamics Corp., Fort Worth, Texas. The $700,000 machine was designed and built by Computer Engineering Associates, Inc., Pasadena, Calif. When assembled, the computer will have a total length of 91 feet.

The unit will be used for the flexible modeling of missile and aircraft systems. The computer makes use of the analogy which exists between electrical circuit networks and physical systems. Such physical systems as mechanical, elastic, thermal, hydraulic, fluid flow, and even nuclear systems are describable mathematically by equations identical in form to those which describe electrical system networks that are either predominantly or entirely made up of passive elements—resistors, capacitors and transformers.

The capacity of the direct analog computer to represent complex systems exceeds that of conventional electronic analog computer installations. The value of the direct analogy is particularly evident in observing the effect of changes of system parameters on system behavior.

Radiation Effects on Electronics Studied

Boeing physicists have initiated a series of studies to determine the effects of nuclear energy on transistors used in the IM-99 *Bomarc* missile. From the tests, the physicists hope to establish the vulnerability of the missile's electronics system to radiation from an atomic bomb explosion.

The tests have been conducted near atomic pile sites at Arco, Idaho and Los Alamos, N.M. Transistors, operating in an electronic circuit, are exposed to nuclear radiations in these tests. Oscilloscopes show how the transistors are functioning and what changes are caused by the radiation.

Experience has shown that three things can happen to a missile in the vicinity of an atomic explosion: first, a sudden overpressure which is powerful enough to rip off wings if the missile is too close to the center of the explosion; second, a searing blast of heat that could burn up the missile; third, the effect of nuclear radiation.

Because damage from nuclear radiation has a longer range than does damage either from overpressure or from blast heat, *Bomarc* physicists are working to solve that problem as it affects transistors.

see AC

. . . volume producing

gyroscopes

. . . setting the world's highest standards of quality

Several manufacturers today can and do build precision-made gyroscopes. Others may produce less precisely-made gyros in volume. But, AC is the only maker of gyroscopes to produce both highest quality and highest volume! These gyros are held to such close tolerances in manufacture that the finished product can instantly sense rotation so slight that it would take years to complete a full circle. Yet they are durable enough to withstand 5,000 to 7,000 hours of continuous operation without appreciable loss of sensitivity. Sizes now available for immediate delivery include 75×10^6; 10×10^6; 2×10^5; 1×10^4.

NEW RATE GYRO FOR SEVERE AMBIENT CONDITIONS

DESCRIPTIVE DATA

- EXCELLENT LINEARITY: 0.25 % of full scale.
- LOW HYSTERESIS: Less than 0.1 % of full scale.
- LOW THRESHOLD: Less than 0.01 degree/second.
- MICROSYN PICKOFF: Variable reluctance type providing infinite resolution and high signal-to-noise ratio.
- FULL SCALE RATE: Up to 1000 degree/second.
- FULL SCALE OUTPUT: Up to 12 volts.
- RUGGED: Withstands 100 G shock.
- VIBRATION: Withstands 15 G to 2000 cps.
- SIZE: 2 7/64" diameter 4 5/16" long.
- WEIGHT: 2 lbs.

Honeywell Rate Gyro
Type JRT
Shown actual size.

Now! Constant Damping
Over Entire Operating Temperature Range

This new HONEYWELL RATE GYRO, Type JRT, is a precision instrument for measurement of absolute rates of rotation in inertial space. Fluid viscosity is electromechanically controlled to maintain a constant damping ratio over the entire operating temperature range of −65°F. to +175°F.

The Type JRT is designed expressly for flight control of long range missiles and flight instrumentation in missiles and aircraft where ambient temperatures are not controlled . . . and at the same time where low threshold, minimum hysteresis, excellent linearity, high natural frequency and ruggedness are essential. Honeywell inertial components and engineering experience are available to assist in the solution of your Gyro system problems. Write for Bulletin JRT . . . Minneapolis-Honeywell, Boston Division, Dept. 45, 1400 Soldiers Field Road, Boston 35, Mass.

astrionics

By Henry P. Steier

TRUE STORY OF RUSSIAN SCIENTIST A. A. Blagonravov's visit to Naval Research Laboratory's Minitrack I test facility at Blossom Point, Md. In Washington for the International Conference on Rockets and Satellites as part of the IGY, Blagonravov accepted an invitation to hear first U.S. recordings of Sputnik's signals. Listening for a while, he then remarked, "Da, I recognize the voice."

SPUTNIK (or more correctly Spootneck, which means "fellow-traveler") is causing more than anxious thoughts on the state of U.S. missile science. It's delaying to some extent development of gyros and accelerometers for our missiles. Word comes from Minneapolis-Honeywell Co. Aero division engineers that every few hours Sputnik's 20.004-megacycle signal raises havoc with some of their precision gyro measurements. Basic timing standard used by M-H engineers is Bureau of Standard's 20.000-mc transmission from station WWV. Difference between it and Sputnik's signal is only four kilocycles. This causes beats between the two. Engineers wonder how long they'll have to live with the interference.

WHOPPING LONG ANTENNAS are trailing along with Sputnik. Two antennas are used to handle the 20- and 40-mc transmissions. There are four antenna elements. Two are nine feet, six inches long; two are seven feet, 10½ inches long. Rather than mounted around the hemisphere of the satellite ball, they are mounted on one side and appear to be designed to act as trailing elements.

ALL THIS TALK ABOUT "EXACT" KNOWLEDGE of the Sputnik's orbit based on our calculations should be taken with a grain of salt. Some good data has come from optical measurements. However, considering the available optics, poor weather and the radio tracking limitations, the orbit calculations leave much unknown.

CAUGHT UNAWARES WITH ITS MINITRACK I and II stations tuned for our 108-mc frequency, the engineers at NRL have been operating under full steam to convert quickly. Main reason for choice of 108 mc was low ionospheric refraction of radio beam at that frequency. Refraction is 6¼ times worse at Sputnik's frequencies.

AT 108 MC, A TRACKING ANTENNA giving good angle resolution and non-ambiguity can be built on a 500-foot base line. Much more space is needed for lower frequencies. So we are still handicapped by the real estate thus far acquired and although our engineers are converting Minitrack I and some of the simpler type II stations to track the 40-mc frequency, the angle resolution will be limited. Higher frequency was chosen as best of the 20-40-mc evils. Refraction goes down as the square of the frequency.

DESPITE THE SUPERB PERFORMANCE of Army's *Jupiter* flights with high accuracy (Astrionics column, September), it appears the Air Force has a good argument for its use of floated gyroscopes instead of air-bearing types in the ICBM's control system. Top floated-gyro engineers say that producibility and performance repeatability problems plague air-bearing gyro producers. AF arguments for its missiles always hinge on producibility of the whole weapon system.

IS SPUTNIK'S SIGNAL CODED or not? Engineers who have watched the signal on oscilloscopes say it definitely appears to go from unmodulated to modulated wave forms. The regularity indicates it's strictly a matter of periodic switching and not atmospheric problems. A separate group of government researchers are tackling the decoding aspect but don't hold much hope for results.

NO GETTING AWAY FROM IT!

Here's the Army's answer to a major problem in U. S. defense. Hawk, recently-revealed missile, hunts and destroys invading aircraft *even at tree-top altitudes!*

Raytheon radars of unique design give Hawk its amazing low-level ability in the blind zone of conventional radars.

This aptly named 16-foot missile is launched from fixed installations for the defense of U. S. cities. Highly mobile, Hawk can also travel with fast-moving land forces, or be carried by helicopter or plane.

Raytheon, with more than a decade of pioneering in guided missiles, is prime contractor for the complete Hawk weapon system.

telemetry for tomorrow:

TV allocations and split responsibility hamper rapid missile progress

By Henry P. Steier

IS U.S. TELEVISION broadcasting hamstringing our missile technology? One official of a key astrionics company thinks so. Many informed observers in the industry have implied it at professional gatherings.

MISSILES AND ROCKETS has learned that limited allocation of frequency space for telemetry and divided responsibility for data handling pose grave bottlenecks in achieving U.S. missile supremacy. This, from a company which has done an outstanding job getting the results of missile tests to prime- and subcontractors.

The company is Radiation, Inc., Melbourne, Fla., which since 1950 has played a significant role in that part of missile technology which might be termed "the silent service." It designs, builds and uses astrionics gear which tells missile engineers how their brain children are performing.

The business is the quiet part of an industry of ear-splitting rocket exhausts. One word, *speed,* probably keynotes a major part of Radiation's work. From the start the company dedicated itself to finding ways and means of quickly getting, and reducing to the language of computers, the data that comes from a myriad of wavy oscillographic records on flights of manned and unmanned vehicles.

Starting out as an engineering group which designed systems for acquiring data from manned aircraft, the company now finds an increasingly bigger job for itself during the transitional period from aircraft to missiles.

New, giant ICBM tracking antenna designed by Radiation, Inc. Unique feed system at center of the reflector gives conical scan. Antenna automatically homes on telemetered signals from the missile. Rate-memory circuit continues tracking during fadeout or noise period.

Conrad H. Hoeppner (left), technical advisor, and George S. Shaw, vice president for engineering, Radiation, Inc., which is equipping Air Force test range from Cape Canaveral, Fla., to Ascension Island with ICBM tracking telemetry antennas.

This is because, with man eliminated, engineers are forced to collect far more data through telemetry. As the distance over which the vehicles operate has increased, data reception problems have multiplied.

Today, Radiation is the prime contractor for the world's largest automatic tracking telemetry antennas. They were specifically designed for our ICBM program. From these antennas will come the first indication that the U.S. has a workable ICBM.

Four of the 60-foot diameter, 1000-mile range, supersensitive antennas are being built. One is already in place on the island of Antigua, BWI. The others will be installed at Cape Canaveral, Fla.; Fernando de Noronha, Brazilian penal colony island; and Ascension Island, 5080 miles from the start of the range. One will be a spare.

The extremely long range of Radiation's TLM-18 antenna system will also make it useful for satellite and interplanetary rocket programs. It has a high gain of 28 decibels and the 1000-mile range is achieved when missile-borne transmitters use 30 watts power.

Located at the focal point of the 60-foot reflector is a rotating-lens system made up of 60 metallic disks. The feed to the lens system is off center and rotated at 10 cycles per second to produce a conical scan pattern.

The lens disks are rotated together at 600 cps in front of a wave-guide feed and form an artificial lens. Result is illumination of the target area at 10 cps and an overall beam pattern about five degrees wide. The lens is covered with a fiberglass dome.

The tracking system includes a rate memory device so that during momentary signal fadeouts the antenna will continue automatically to track the target. Tracking will continue up to 20 seconds after a fadeout.

Radiation's vice president of engineering, George S. Shaw, has expressed alarm at the lack of attention which data collection and processing have been given in U.S. missile efforts.

"There is no shortage in American industrial capability to put the hunks of sewer pipe together and fly the things," he said. "It's not like putting together a complicated airframe structure such as the B-58 where we know millions of man-hours and chronological steps are needed so you cannot shortcut."

With a missile, Shaw explained, even though the full vehicle development is incomplete, you can fire it and get information. But, he contended, this is not doing the good it should.

One of the gravest bottlenecks in getting data back to engineers on missile performance, Shaw said, is the limited space in the radio spectrum allocated for radio telemetry. Legally radio telemetry has been allocated a 20-megacycle wide-band split between the 220- to 235-mc region. The myriad telemetry users must all share the same 20 mc, often on a time-shared basis, which delays tests. Some bootlegging is allowed on a noninterference basis from 235 to 265 mc.

"Now with so much of our national defense depending on these missiles and aircraft," Shaw said, "telemetry has to be used for missiles, aircraft and atom bomb tests. Every form of data collection, tied together by radio, uses the narrow assigned bands.

"This is essentially the band width that we use for three or four television stations, and almost every city of 100,000 to 200,000 has that much band width allocated to it for television for pleasure. Thus we have allocated TV bands from about 500 mc to 1000 mc, or 500 full megacycles, which we have only used on a scattered basis."

And he added, "It is completely incongruous situations like this that are degrading our technical outlook." Arguing for better government control of our band space resources, Shaw said, "Let them squander a little of this (TV) band on radio telemetry in the same way we squander gasoline and tires on Sunday afternoon.

"Certainly the Soviets have no TV-channel interference problems. If they did, they'd put them off the air. They've put the problem at a higher level of importance than we have. Let's hope we can be as dynamic in changing our ways as Russia was after 1945.

"We sort of hamstring ourselves in the way we work things out. Telemetry is especially important during this transition to unmanned flight. The cycle will reverse, however, at some point and may occur sooner than you think. Probably it will occur on the Soviet side first because of their difference in philosophy on the value of human life. The cycle will reverse back to the manned vehicle." This will not eliminate the telemetry need, but will ease the problem and enable use of man to read data.

In the 2000-mc band there are 100 mc available to telemetry users. However, use of the space is surrounded by problems. Interference with certain radars occurs. Transmitting equipment for a given efficiency gets much larger because of the microwave plumbing needed.

At 200 mc, an input of 200 watts gives an output of perhaps 100 watts. To get the same power at the higher frequency, 600 watts input would be needed. This is a big handicap when batteries or solar cells are used as in a weight-sensitive satellite or missile.

To get the same antenna gain at the higher frequency as the low, the antenna aperture must be the same. But the beam angle goes down. In the case of Radiation's 200-mc ICBM tracking antenna, the beam angle is about five degrees. If the frequency were 2000 mc, the angle would go down to one-half degree. This would seriously affect ability to track the missile and

raises the probability of its loss if its trajectory becomes erratic.

Shaw said very little money has been spent on R&D for 2000-mc telemetry. The advent of further developments in the use of the MASER (magnetic amplification by stimulated emission of radiation) might aid the efficiency-weight problem. But such developments are in the multimillion dollar bracket.

Another advantage predicted by Shaw if low-weight MASERs are built is increased missile accuracy. Net effect of using the ultra-high frequency stability of the MASER might be to increase ICBM accuracy within five miles, he believes.

Radiation together with other companies is doing whatever is possible to shorten the time lag brought about by data reduction. At this time the company uses FM/FM pulse-width modulation equipment for data transmission. On the ground this is converted to pulse-code modulation for input to the computer.

Every one of the IRBM and ICBM programs have been aided by Radiation's work either in the form of components or systems. Data-processing equipment supplied for the B-58 program was a recent contribution to the aircraft field.

The equipment assembled by Radiation is not necessarily made by the company. Most of it is purchased and modified to suit the needs of a specific system.

Shaw said, "Certainly we are not needed from the standpoint of production. We have never produced large quantities of equipment and don't intend to build a large production outfit. The nation has that capacity. What we do need is the capability to engineer specific hardware required in a small quantity. There is where Radiation fits in."

When a missile contractor is given a job to produce a missile, he does not develop new means of instrumentation. It is specifically written that he use available test-equipment facilities. He does not have R&D money for improved instruments. All he can do is repackage what is available to suit his vehicle.

"The telemetry industry has not and dares not, for economic reasons, to proceed developing lines of needed equipment. Quite frankly, there are few new instrumentation techniques that go beyond merely repackaging, stabilizing a transmitter a little better or improving the gain of a receiver.

"Beyond this, you get into millions of dollars investment, and dollar sales have not warranted that the electronic giants spend the money on R&D. So the prime sources of R&D have failed to provide new telemetry and dynamic instrumentation at the rate needed for the satellite, ICBM and moon vehicle problems," Shaw explained.

Another serious bottleneck is that radio telemetry in the United States has been a split responsibility.

First, the vehicleborne equipment is the responsibility of the prime contractor. But the missile test centers have responsibility for the data-collection equipment, and some data-reduction equipment. Some of the data-reduction job goes back to the prime contractor.

This split responsibility wastes time and missiles. This is because of hours, days and even months spent in reducing the data or transferring it to different interests, since some of the reduction is done by the prime contractor, who might be thousands of miles away.

If the contractor gets the information on magnetic tapes in oscillographic form, it must reduce the records to numbers before calculations can be made and decisions reached on a vehicle or subsystem's performance.

"The thing that gets so important here is that with our missile production capability we can fire test missiles at a fantastic rate on a weekly or monthly basis. The only thing is that with our data handling techniques it might well be three or four months before the data

HARRISON, N.J.

is fully available for modification of how the next test should take place," Shaw told m/r.

And he added, "We probably partially waste two vehicles. We fire simply because we don't know enough about the first flight to go right ahead and do something immediately."

An example of how time is wasted because of limited data-processing capability is the procedure by which a missile contractor might reduce the data supplied to him on a magnetic tape.

Some companies use lines of girls who read the paper oscillographic tapes manually and put the information in digital form on a consolidated record. Punched cards are made from these, and then run through a computer.

This is not altogether necessary with today's advances in data acquisition and automatic reduction. One of Radiation's major efforts is to design and fit together systems to telemeter, process and reduce data to digital form on magnetic tapes. In this form it is compatible with high-speed input capability of digital computers.

Some companies such as AC Spark Plug and General Electric have recently built advanced data-reduction systems to shorten the time lag. Building systems for other companies to do fast data reduction is a primary job of Radiation's data systems division.

Needed badly is some form of more accurate acquisition in the vehicle. Some form of pulse-code modulation equipment in the vehicle would speed up data reduction. Next step after that would be to pick up the information in digital form.

If this were done, the digital data could be telemetered directly into a computer and the test results would be available almost immediately for assimilation by engineers.

The field for development of digital transducers is wide open, but lack of money for the R&D presents a pessimistic picture for any early big gains in this field. Radiation has entered the field of developing digital transducers because of the tremendous potential.

The company was started by its president, Homer R. Denius, and Shaw with a capital outlay of $25,000. Preliminary estimate of 1957 sales is $7 million. There are five operating divisions: research, data systems, RF, instrumentation and product. The company also has facilities at Orlando, Fla., as well as a nationwide organization.

A systems research group was recently added to the company to study potential fields of endeavor. It includes Lloyd Everyingham, James Brantley, John Doolittle, Armand Tanguay and Don Rhodes, all formerly with Cornell Aeronautical Laboratory. L. W. Sieck, formerly with AF Development and Planning Board, is also with the new group. ★

announcing CEC's potentiometer pressure pickups

...designed for missile applications

Far superior in resistance to shock and vibration, the extremely rugged Type 4-380 Potentiometer Pressure Pickup is ideal for missile operation in a high-vibration environment. It is designed for absolute and differential pressure measurements of non-corrosive fluids in ranges under 100 psi . . . operates at temperatures from −65 to +200°F. It is approximately one-half the size of typical potentiometer pickups on the market today.

The new Type 4-380 weighs approximately 7 oz. Packaged complete with a flange base, it can be bolted directly to a mounting plate. Size of the mounting flange is 2¼" square; pickup height is 1⅝". A miniature, threaded connector is supplied for easy cable connection. All fittings, electrical and pressure, are parallel to the base.

The inherently high-level d-c output eliminates the need for impedance-matching or signal-amplifying equipment. Pressure fluid is admitted directly to a force-summing pressure capsule—remains external to the potentiometer system.

micromation for system miniaturization

Missile applications have supplied the catalyst for coordinated miniaturization

By Sidney Herman
Waldorf Instrument Co.

RECENT efforts in missile instrumentation have concentrated on independent element miniaturization. Solving the problem of miniaturizing the overall system required more than mere selection of miniaturized elements and components. The functional unit had to be considered as an entity, and each designed with respect to the other parts in the functional system. The design process is a closed-loop in which the basis for selecting any one component depends upon feedback from other elements in the loop.

Application of this design philosophy to coordinated system miniaturization is Micromation.

The Micromation concept has been applied in missile evaluation to typical computing, controlling and indicating functions which are parts of more complex systems. The systems include ground test equipment, preliminary firing, checkout units, and analog converters used in missile guidance. It is possible for the design engineer to proceed directly from his system block diagram to procurement of functional modules after specifying inputs and outputs. The intermediate stage-by-stage design is eliminated.

A common instrumentation problem is that of servoing data. Input data may be received from any one of a number of transducers: synchro, potentiometer, strain gauge, thermocouple, etc. The desired output is a shaft rotation equal to a function of the input value, linear or otherwise.

In the normal design process, this functional block would be broken down into subunits as shown in Fig. 1. Requirements for each unit would be analyzed and performance specifications established. Some requirements would be compromised to permit use of available components.

As a result of the Micromation process, a proof-tested combination of miniaturized subunits is available and is assembled into a functional module. This module performs the desired servo repeater operation with matched subunits, in minimum size and weight, without sacrificing power, reliability or ease of maintenance.

As a further result of the Micromation process, the burden of subsystem engineering is shifted from the system designer to specialists. The functional module incorporates the latest proven techniques of miniaturization and subsystem design.

One of the first examples of a Micromation product is a completely self-contained synchro-type servo-repeater module presently in production at Waldorf. The unit, Model No. W1801, is two inches in diameter and four inches long. It contains a transistorized servo amplifier, size eight servo motor and control transformer, power supply, and gear head. One of the preliminary models is shown in Fig. 2. Each component is also constructed as a miniature modular assembly thus maintaining a simplicity of maintenance. Fig. 3 shows each of the components that, when assembled, comprise the repeater.

The complete repeater unit weighs 13 oz. and is installed in the same manner as a motor or synchro component.

Production units have been tested under varying conditions of temperature and supply frequency. Results are shown in Figs. 4 and 7.

There is an evergrowing trend toward the use of digital computing

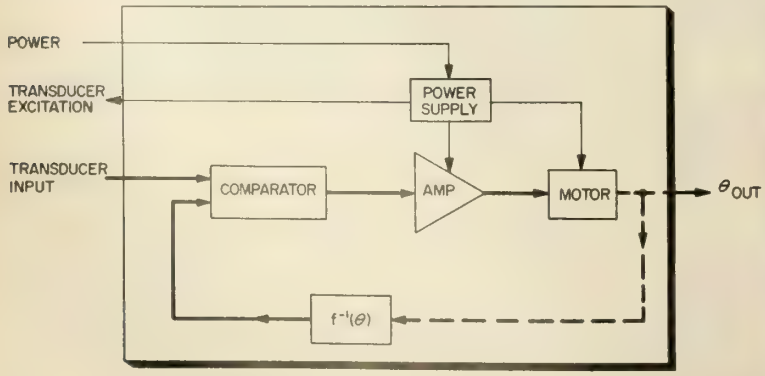

Fig. 1. A normal functional servo block would be broken down into subunits as shown.

Fig. 2. Synchro-type servo-repeater module.

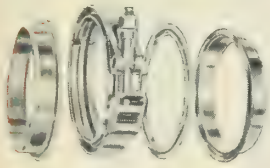
NEW MARMAN CONOSEAL TUBING JOINT

ASSURES PERFECT FLUID LINE SEAL AT EXTREME TEMPERATURES AND PRESSURES

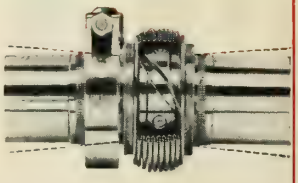


Problems of connecting tubing and ducting of dissimilar metals subject to extreme temperatures can be solved with the new Marman Conoseal Tubing Joint. An all-metal joint, it provides metal gasket compression with the flexibility and sealing qualities formerly obtained only through use of organic seals. The Conoseal Joint withstands linear deflections up to 1/16-inch without sacrificing a perfect seal. The seal is maintained under extreme pressures and temperatures even on joints with material transitions, in which steel and aluminum alloy plumbing are joined

The Conoseal Tubing Joint is available in three different operating performance ranges to meet varied applications. Standard sizes from 1″ to 12″ O.D. tube size, with special sizes designed to your requirements. Write today for full engineering details.

Operating Range	Temperature Range (°F.)	Max. Pressure (3″ Size @ 70°F.)
Low	—300 to +750	1300 psig.
Medium	—300 to +1000	3300 psig.
High	—300 to +1600	testing still in progress

HIGH PRESSURE PNEUMATIC SYSTEMS • LIQUID OXYGEN SYSTEMS • HYDRAULIC SYSTEMS • EXHAUST SYSTEMS • FUEL SYSTEMS

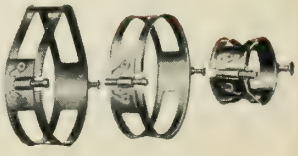


Marman J-11 LIVE Joint Systems

For connection and disconnection of aircraft tubing. Flange ends mate with all-metal gasket to provide positive seal for fluid and gaseous systems up to 2000 psi. in 1″ size, at operating temperatures from —300°F. to +1000°F., available in 1″ to 12″ O.D. tube sizes.

Marman MB-11 Universal Joints

For supersonic aircraft duct systems subject to severe flexing and vibration. Designed to allow 10° deflection with minimum pressure drop. For operating temperatures from —300°F. to +800°F. Can be used with J-11 Joints or as an integral part of the ductwork. In 2″ and 3″ O.D. tube sizes.

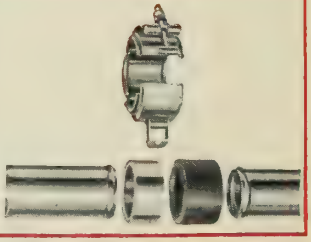


Marman In-Line Check Valves

For control of hot bleed air on jet engines. Designed for full flow without flutter or high temperature distortion. Can be used with Marman J-11 Joints. For operating temperatures up to 1000°F. and pressures from 28″ vacuum to 300 psi.

Marman Lightweight Instrument Clamps

For quick, easy installation of instruments and light accessories. Designed with weight savings up to 60% over standard clamps, this AN-approved type is non-magnetic for universal use. In AN 1½″, 2″ and 3¼″ sizes, plus special configurations and sizes.



Marman Band Clamps

For easy connection and support of components and accessories. Marman offers a wide range of clamp types and sizes, with four types of latches: T-bolt, quick-coupler, saddle, or thumb screw. In corrosion-resistant stainless steel and aluminum alloy.

Marman Flexible Couplings

For simplifying connection and disconnection of airframe and engine components joined by tubing or ducting. Flexible sleeve in coupling holds seal under flexing. Interchangeable sleeves available for hot air, aromatic fuels or synthetic oil. For temperatures from—70°F. to +500°F., in sizes from 1″ to 10″.

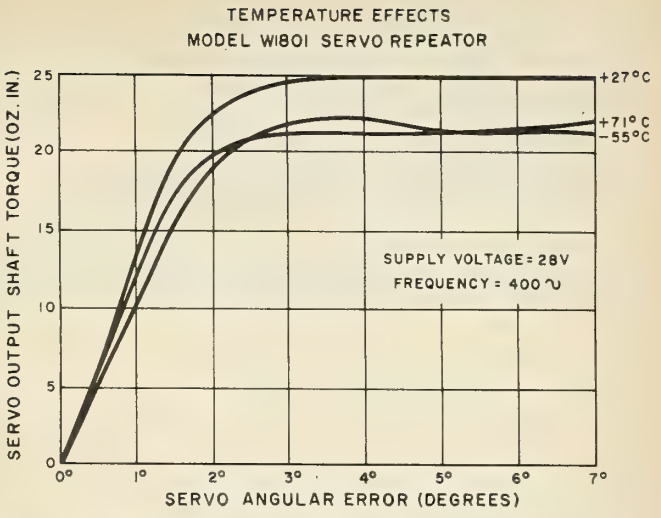

Fig. 4. Results of tests of unit of motor torque vs. input voltage.

techniques in instruments.

A common problem encountered, however, is that of converting the input analog voltages received from transducers into digitized outputs equal to a desired function of the input valve, linear or otherwise.

The treatment of the servo repeater problem, modified by addition of a digitizer as shown in Fig. 5, may be applied. For example, to convert synchro input linearly, a unit such as the Model W1801 Synchro Servo Repeater with the addition of a digitizer on its output shaft may be packaged as a completely self-contained module, each component constructed as a miniature modular assembly. The resultant Micromation package would be a "black box" with provisions of a synchro-transmitted input and a digitized electrical output.

The servo amplifier and motor requirements are satisfied by the same proof-tested components used in the repeater (Fig. 5). A servo amplifier Model W1803, presently being produced, is another result of applying the Micromation concept.

The unit, a transistorized module

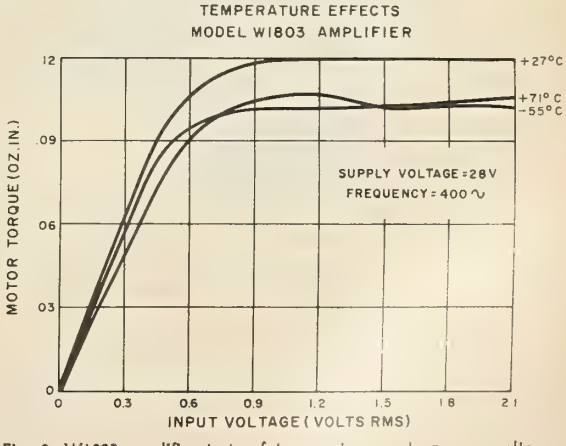

Fig. 8. W1803 amplifier tests of temperature on torque vs. voltage.

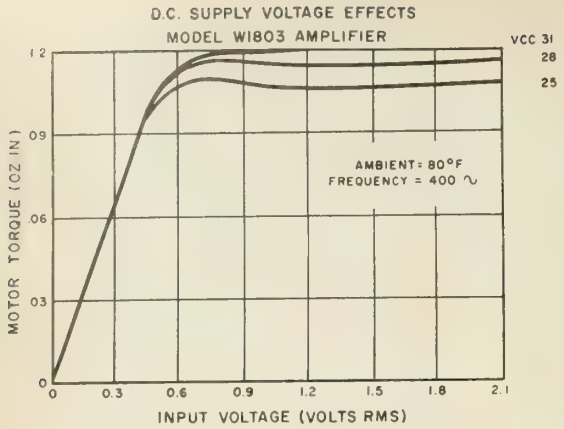

Fig. 9. W1803 amplifier tests of dc voltage on torque vs. input.

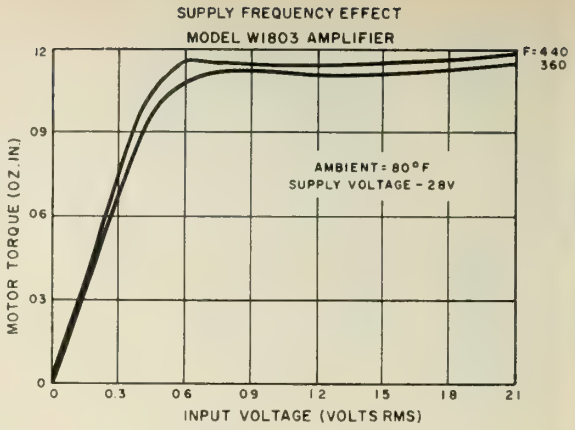

Fig. 10. W1803 amplifier tests of frequency on torque vs. input.

13/16″ in diameter and 2¾″ long, weighing 2 ounces, is designed for use with 26-volt, 400-cycle, size 8 or 10 servo motors. Capable of being mounted in any position and requiring only a 28-volt, dc power supply (at 125 milliamperes), the 90° phase shaft required for two-phase induction-type servo motors is obtained directly. Therefore, no external capacitors are required.

Production units have been tested under varying conditions of temperature, supply voltage, and frequency. The primary consideration during all these tests was the amplifier's function in the system. As a servo amplifier it is basically required to drive the motor to produce an output torque proportional to the error signal input. Thus, the motor output torque rather than output voltage was the measured characteristic of merit. Results are shown in Figs. 8, 9, and 10.

Right Triangle Solver

A problem continuously arising in analog computations is that of resolving a vector quantity into mutually perpendicular components, or, its converse, obtaining the vector quantity from its components, Fig. 6 illustrates the manner in which a Micromation module would solve the latter in a self-contained subsystem package.

The same off-the-shelf, modular servo amplifier package (Model W1803) and motor previously described, are used. The other elements within the system unit are treated in an identical manner.★

TECHNIQUES and DEVELOPMENTS in oscillographic recording

FROM SANBORN

CIRCUIT DESIGN AND TYPICAL USES OF THE "150" CARRIER PREAMPLIFIER

One of the most frequently used plug-in front ends for Sanborn 150 Series oscillographic recording systems is the Model 150-1100 Carrier Preamplifier, since with it a "150" system can record such variables as force, temperature, strain, pressure, displacement, velocity, flow, acceleration — or any variable which can be expressed as a suitable input signal by a transducer. The "1100 Carrier" will operate with a variety of different transducers and bridge circuits, which will be mentioned later on.

In the block diagram (Fig. 1), a push-pull oscillator provides an excitation voltage of about 5 v. to the transducer at a standard frequency of 2,400 cycles or optional frequencies of 600 and 1,200 cycles, using plug-in components. This excitation voltage also feeds the Balancing, Calibration and Zero Suppression circuits. (The Balancing controls allow correction of resistive and reactive signal leakage from the transducer, so that at zero load the net signal to the Preamplifier is zero. The Zero Suppression feature permits bucking out a large static load so that a small part of the load can be expanded over the full recording chart. The Gage Factor control allows the zero suppression range to be made equivalent to some convenient transducer load, or the full load rating of the transducer, and also causes the calibration signal to represent 2% of that load.) Transducer output is fed to the transformer through the Gage Factor potentiometer, across which the Balancing-Calibration-Zero Suppression circuits develop a voltage effectively in series with the transducer output. The mixer receives a suppressed carrier AM signal and re-inserts a carrier component, to make its output a conventional AM signal whose modulation represents the transducer load. The modulation signal (whose amplitude and polarity represent magnitude and direction of transducer output) is recovered by the demodulator and fed to the output amplifier, which in turn excites the Driver Amplifier and recording galvanometer of a "150" system.

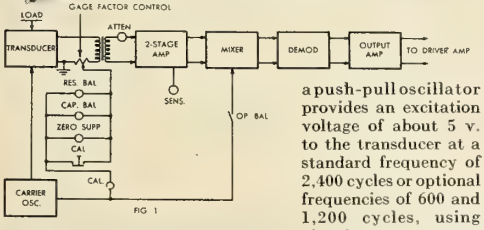

FIG 1

Transducers which may be used with the Carrier Preamplifier include strain gage half-bridges or full-bridges, commercial resistance or reactance bridges, differential transformers and resistance thermometer bridges. The transducer chosen should provide at least 18.0 microvolts per volt of excitation at the minimum load to be recorded, for a one cm. deflection; impedance should be 100 to 1000 ohms. With strain gages, normal operation provides sensitivities of 50, 20 or 10 micro-inches per inch for each cm. on the recording, depending on the number of active gages. With resistance thermometers, if 1°C. or 2°F. per cm. stylus deflection is sufficient sensitivity, the user can construct his own resistance thermometer by including a 3 ohm coil of copper wire in one arm of an equal arm 100 ohm bridge.

Helpful information about the use of transducers with the 150-1100 Preamplifier is contained in the following Sanborn RIGHT ANGLE articles (reprints on request): Coupling Differential Transformers, Aug. and Nov. 1956; Filter Networks for use with Force Dynomometers, Nov. 1956; Calibration with 1-, 2- or 4-arm Strain Gage Bridges, Aug. 1955; Theoretical and Actual Applications of Bridge Circuits, May and Aug. 1954.

Wing flutter recording to infrared research . . . with the versatile "1100 Carrier"

Today, Carrier Preamp-equipped Sanborn "150" systems are being used for frequency response tests of process control system components; to record shaft deflections of fluid mixing equipment; in infrared research . . . vehicular traffic studies . . . submarine hull vibration measurements. Applications are limited only by the transducers available.

These are applications of only one "150" front-end; *eleven* more interchangeable, plug-in Preamplifiers increase the scope of Sanborn oscillographic recording systems to meet an almost infinite variety of research, production and field testing requirements. All Sanborn "150" direct writing systems record inkless traces in true rectangular coordinates; all provide 1% linearity; Basic Assemblies — equipped with *your choice* of Preamps — are available from one- to eight-channels, packaged in vertical cabinets, portable cases, or specially modified housings.

Technical data and help with your oscillographic recording problem are always available from Sanborn.

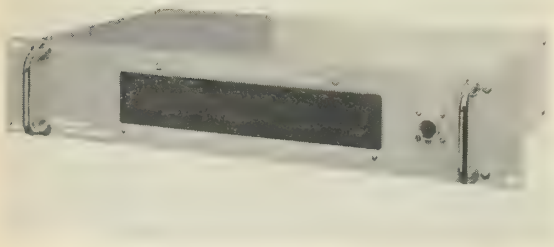
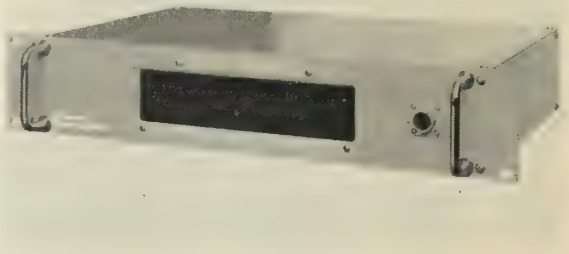
modules for digital instrumentation



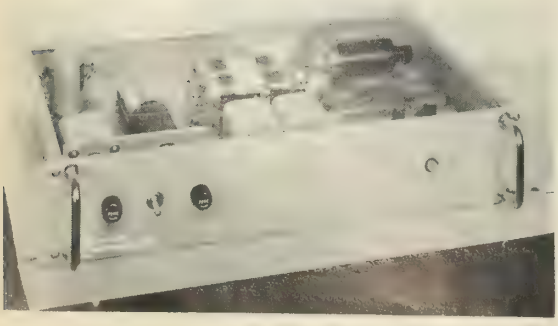
By Walter H. East, Vice President
Electro Instruments, Inc.

DUE TO THE DYNAMIC character of current expansion in the electronics industry, the specialized precision instrumentation field is more than ever confronted with the problem of equipment obsolescence. Such obsolescence is usually caused by changes in problem requirements but it is frequently occasioned by inflexibility or incompatibility in the design of the instruments themselves.



One solution to this problem is an integrated, modular instrument design. The basic modules should be capable of combining to form precision instruments as well as integrating with other instruments and machines to construct complete data handling and automation systems. Also, the development of new instruments should extend the usefulness of the instrument line and maintain a current position rather than cause obsolescence or complete loss.

There is also the obvious advantage of easy maintenance—no small problem in complicated electronic packages. With modular instruments it is a simple matter to substitute an interchangeable module and keep the system in operation.



Electro Instruments, Inc. has been manufacturing a complete line of precision digital instruments for automatic measurement of DC and AC voltages, resistance, DC and AC ratios. These basic instruments can also be modified for operating with machine read-out equipment or for integration into systems. However, each change or modification entails new engineering and since customers cannot always predict future needs for their instruments, modifications at a later date are always difficult. Then, too, there are inevitable minor changes required for specific

Five-digit digital voltmeter module.

STACKABLE

MORE VERSATILE THAN EVER . . .

the new Sun . . .

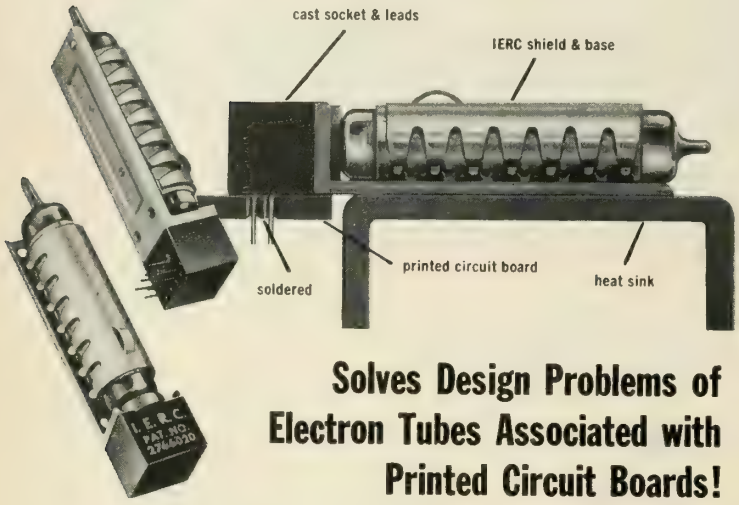
ELECTRIC POWER ABSORBER

Newly designed—to meet critical space and weight requirements. Front panel makes possible cantilever mounting of several units horizontally or stacked in tiers.

Mounting panel is only 13 inches square. Overall length is 18 inches—weight approximately 18¼ pounds depending upon capacity.

Amazing efficiency! 10 to 15 KW power absorption per unit—up to 2350 BTU's of heat dissipation per pound of weight. No other type of power absorber, air or water-cooled, can begin to match this performance.

Exceptionally well suited to aircraft and guided missile testing and service equipment, this unit has many commercial and industrial applications, too.



You'll want to investigate this versatile unit for your own power absorption requirements. Write today for full details and specifications.

IERC Heat-dissipating "plug-in" Tube Shields for Printed Circuits!

Solves Design Problems of Electron Tubes Associated with Printed Circuit Boards!

IERC's latest heat-dissipating tube shields for round button and flat press subminiature electron tubes solve design and performance problems of tubes associated with printed circuit boards. Standard socket and an Epoxy resin are integrally cast to the shield base. Socket leads extend from the Epoxy casting 90° to plane of base permitting direct plug-in to printed circuits for hand or dip-soldering of connections. Bulb temperatures are maintained to within 5°C of the heat sink temperature per watt of heat-dissipation when shields are attached, as suggested, to a heat sink of proper thickness for conduction or hollow duct types permitting air or liquid circulation. IERC's patented design provides maximum cooling, excellent tube retention, shock and vibration protection under severe conditions. Pertinent dimensions are to .1 inch grid layout.

Heat-dissipating electron tube shields for miniature, subminiature octal and power tubes

Circle No. 101 on Subscriber Service Card.

applications. The complete instrument design common in specialized instrumentation does not readily lend itself to engineering changes.

After due consideration of these problems and others learned from extensive field experience of over 1000 instruments, the new E-I modules were designed to meet the majority of the needs for digital instruments and instrumentation systems.

Each module solves a specific measurement problem and all may be combined and recombined into a variety of instruments. Auxiliary modules are available for complex systems when automatic programming and recording of test data is required. All types of printed forms, punched cards or tape may be obtained for automatic data production.

Basic Module Design

In addition to designing for maximum application flexibility, each module has been transistorized. This advanced circuit design has many advantages besides the obvious reduction in size, power consumption and heat dissipation. It also provides both new and improved specifications plus improvements in reliability and ruggedness.

The basic modules consist of a power module, four and five digit DC and resistance switch modules, AC converter and DC pre-amplified modules. Each unit is packaged in three ½″ x 19″ x 12″ standard rack cabinets. Combinations of instruments are constructed by merely changing interconnecting cables.

The heart of this system of modular units is the switch section unit. These modules enable the user to measure DC voltages from 0.1 mv to 999.99 volts and resistance from 10 milliohms to 10 megohms with an accuracy of 0.01 per cent. Either the voltmeter switch section or the ohmmeter switch section may be obtained in four or five digit models. The switch section modules are very compact and may be installed in the operating position of a control console, eliminating the necessity of a remote read-out.

The movement of the stepping switches is controlled by a new logic program which takes a minimum number of steps and reaches the final reading with a minimum of wear. The mechanical design of the switch section provides a new ease of servicing.

The power unit contains the necessary power supply, the null detecting amplifier, and reference voltage supplies for the other modular units in the system. The use of transistors in this unit has greatly reduced heating effects. The use of temperature controlled Zener

At Moog:
Production Valves
Quality Tested

One reason Moog makes so many servo valves so well is just what you see here—a superbly-equipped test room where every valve is put through its paces. All test apparatus was designed and built by Moog especially to test production valves for performance criteria including flow rate, frequency response, resolution, linearity, and hysteresis. This attention to quality in quantity is your assurance of reliable servo valves for your production requirements.

missile development at **HAMILTON STANDARD**

has created some of the industry's most intriguing openings for:

• Senior Physicists • **Electronics Engineers** • **Mathematicians**

Reply to Robert C. Main, Manager, Electronics Dept., Hamilton Standard Division of the United Aircraft Corporation, Broad Brook, Connecticut

Circle No. 104 on Subscriber Service Card.

Typical automation system constructed of standard E-1 modules. The system automatically scans and measures 400 channels of AC and DC voltages with typewriter readout.

diodes as a source of reference voltage has eliminated any dependence on a mechanically fragile standard cell. By using a transistorized stepping switch drive system, a low voltage controlled flow of power to the stepping switches reduces mechanical wear in the switch with a consequent increase in switch life. Where possible, JAN approved components are used throughout this unit for utmost reliability.

The AC converter and DC preamplifier modules enable the user to extend the use of this instrument for precision measurement of AC voltage from 30 cycles to 10,000 cycles to an accuracy of 0.1% and DC voltages from 10 microvolts to 0.1 mv with an accuracy of 0.02%.

Module System Integration

Automatic checkout systems may be easily constructed by adding scanner and print-out modules to the measurement units described above. The input scanning equipment consists of a master scanner module which contains the visual read-out and print-out facilities for automatically scanning up to 10,000 input test points. The master unit also contains a switching circuit with gold contacts for the first 100 points. To this master unit may be added up to three slave units, each of which contains 300 additional input signal circuits all having gold contacts. If desired, the user may also connect these slave units to function as parallel switch circuits to provide four-wire scanning, thereby minimizing effect of lead resistance when using a digital ohmmeter.

Readings taken automatically by the combination of the input scanning and measurement modules may be recorded in any variety of digital forms by the use of one of the print-out control modules. The printer control unit is designed to operate the Clary adding machine type of printer. Electrical typewriter controls are available for either the Underwood Servotyper or the IBM typewriter. If further automatic data reduction is required, the information may be recorded on punched tape by the use of Flexowriter units. The IBM control units enable the user to record data on punched cards for processing by computing equipment.★

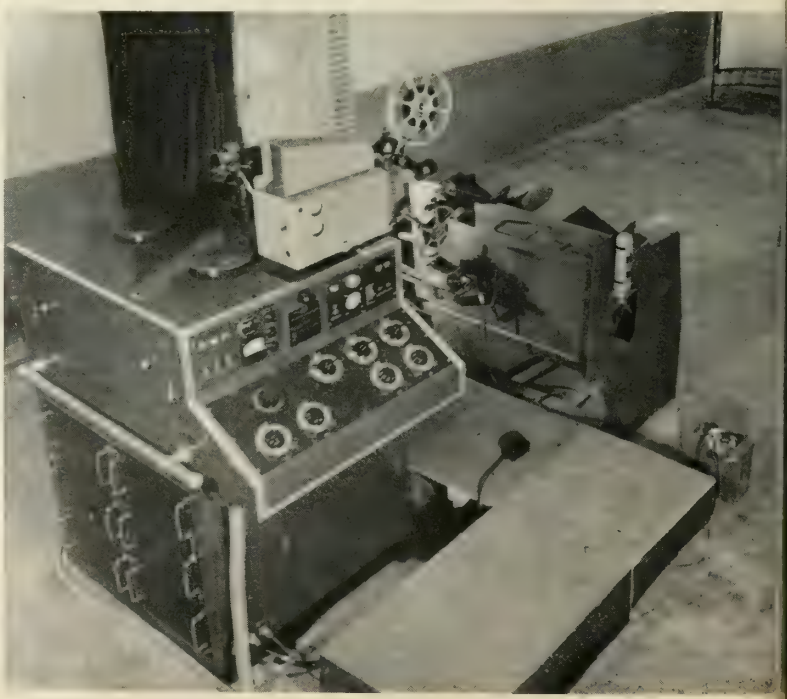
visual trainer for AT missiles

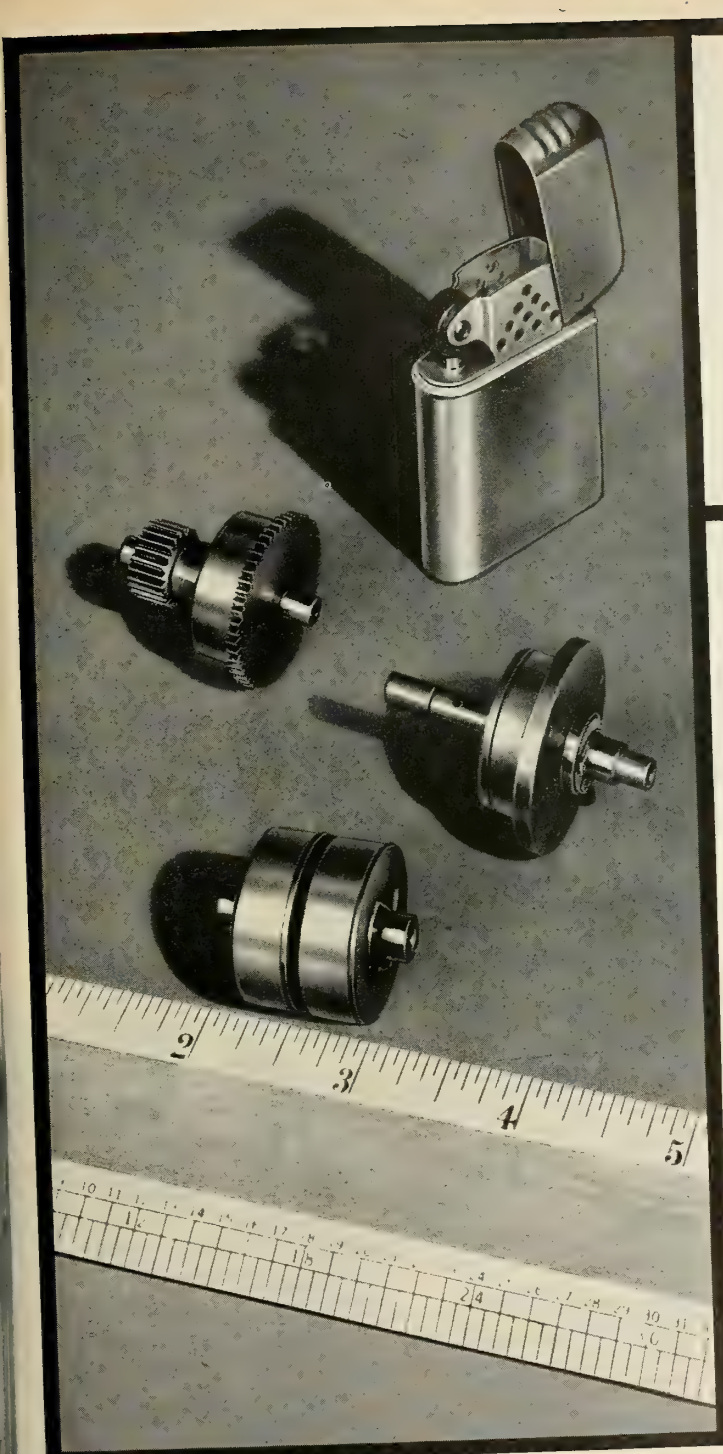
By Frank G. McGuire

REALISTIC TRAINING for realistic cost has been provided for the SS.10 and similar antitank missiles by Giravions Dorand, a French firm. The model DX-40, a cine-simulator, uses motion pictures, a computer and remote control units to provide troop training in wire-guided missiles.

The device enables operators to direct missiles onto a moving target under realistic field conditions while an instructor observes the exercise. The cost of the entire unit is about $57,000, showing a marked economy over usual training methods.



A moving target is displayed on a panoramic screen by the projector. A luminous spot also projected upon the screen represents the missile as seen by the operator. The luminous spot is remotely controlled by the student and corresponds exactly to the position of the missile at all times.



An optical cam system continuously determines the distance between the operator and target, and simultaneously computes the distance between the operator and missile. When these two distances become equal, a special device stops the simulator, freezing the target and missile images. This allows assessment of the exercise—target hit or missed, depending on spot coincidence with target image.

The system allows the instructor to follow and usefully instruct the student during the exercise. He may freeze the action at any time in order to point out particular faults, make corrections, then continue the action.

The device is composed of several units: the main cabinet, housing the

Visual trainer supplants much more expensive method of using actual missiles.

How Much Torque Capacity Can Be Handled In An Inch?

The largest Formsprag clutch shown at left measures less than two inches—weighs about the same as your cigaret lighter—yet delivers more torque per cubic inch than any other available today.

Good news for aircraft, missile and rocket engineers whose job it is to pack more and more power into less and less space. For example, here's how two aircraft component manufacturers have taken advantage of Formsprag's unique clutch design . . .

A landing gear manufacturer has employed Formsprag clutches to over-run the primary hydraulic system so that in case of emergency the pilot can actuate the landing gear mechanically.

An accessory gas turbine manufacturer uses a Formsprag clutch as a disengaging device on a starting mechanism.

If you would like to know more about how Formsprag clutches may be of help in solving your design problems, why not have a talk with a Formsprag engineering consultant?

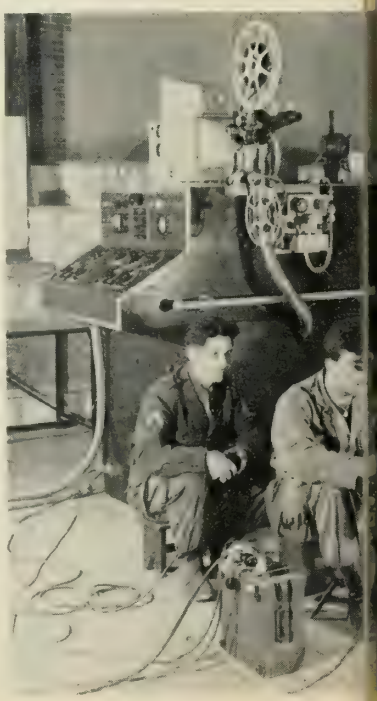
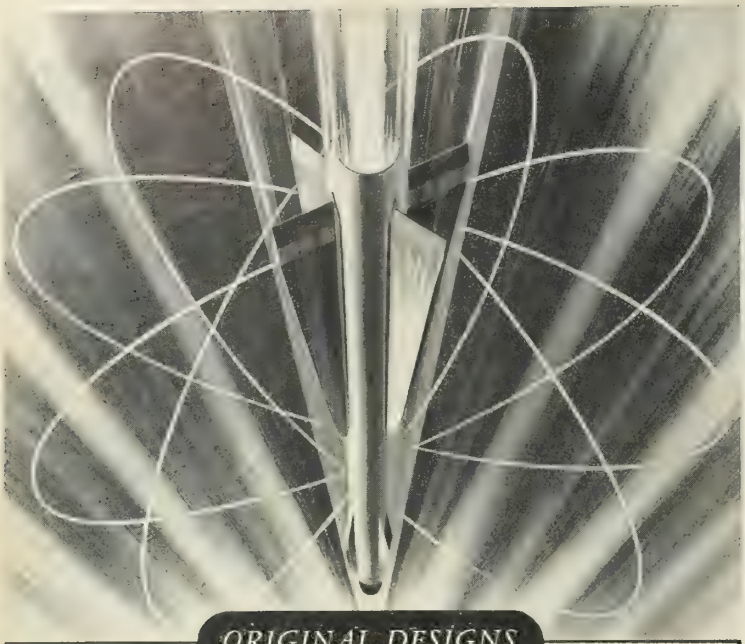
computer, on top of which is mounted the target projector and the missile projector. The front face of this main unit carries the starter and control panel as well as the setting-up console.

A separate cabinet houses the electronic equipment of the simulator, and the panoramic screen is placed about six to 11 feet in front of the student, who holds the remote control box.



The first of these units, the main cabinet and the electronic cabinet, are ruggedly constructed for disassembly and transport by rail, road, sea or air. Special packing cases are provided with the machine.

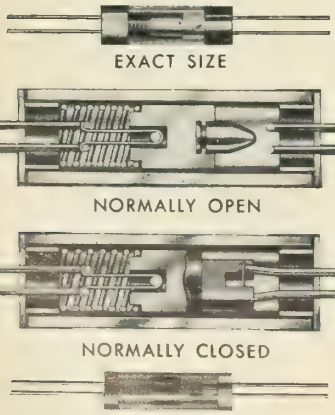


A Debrie projector is used with a mercury-vapor lamp. The projector is equipped with an instantaneous stopping device, allowing a still picture to be seen, and a reverse-running control. CinemaScope projection is obtained by use of an adjustable hypergonar projection lens.

The missile-tracer projector, controlled by the computer, produces a light spot whose size and intensity diminish automatically with increasing "distance" from the operator.

Installation of the DX-40 requires a minimum floor space of five by nine yards, and installation in a trailer is possible. Maximum power required for operation is four kva at 220 volts, ac, single-phase. Unpacked weight of the simulator is about 2400 lbs. ★

Instructor can monitor the exercise, stop the equipment and point out student mistakes.



ORIGINAL DESIGNS

MINIATURE THERMAL RELAYS

with

99.99% PLUS RELIABILITY

New NORMALLY CLOSED RELAYS NOW AVAILABLE. Hermetically sealed by an exclusive process of bonding metal headers to high thermal, shock resistant glass housings. Designs are based on the "fuse burnout" principle and will open or close a circuit *positively* in 0.1 second or other delay times. They can also be safely used as a "squib" or timing mechanism.

Relays have been qualification tested for high performance and are being used extensively on current production missiles and complex electronic equipment.

Withstand extreme conditions of temperature (−100°F to +450°F), shock (250 G's), vibration (20-3000 cps at 40 G's), and precise electrical characteristics with the added feature of visibility.

Our complete environmental testing laboratory samples and certifies daily production.

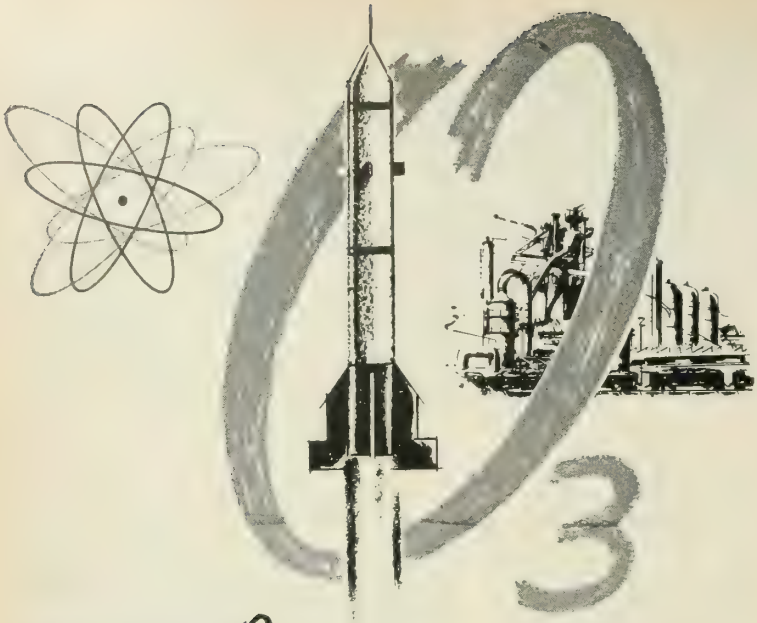
HONEST JOHN artillery rocket depends on G-E electric heating blanket (inset) to bring missile to uniform operating temperature before launching.

HONEST JOHN FIRING SHOWS HOW . . .

General Electric Specialty Heating Maintains Propellant Temperature

Successful launch—and flight—of the Honest John depends upon exact propellant temperature at the moment of firing. A General Electric heating and insulating blanket—which shrouds missile from nose to nozzle—provides and maintains that temperature!

Proper operation of many types of land and airborne equipment, especially at low temperatures, often depends on controlled heat in the right places at the right time. Experienced G-E heating engineers, backed by complete facilities, have already solved thermal conditioning problems on applications ranging from complete missiles and airborne systems to tiny test instruments.



LET US ANALYZE YOUR HEATING PROBLEM. Whether you need a custom-made prototype, or quantity production, investigate G-E "one stop" service for specialty heating products tailored to your specific needs.

WELSBACH Ozone

..new horizons as an oxidant

Ozone provides one of the most versatile oxidants available today. It has the added advantage of introducing nothing but oxygen to the reaction.

Low in cost, efficient and always available, ozone produced by a Welsbach Ozonator might just be the answer to your oxidation problem.

Glance at a few of the applications listed below in which ozone has proved to be a better oxidant. One of them might parallel your problem . . . with ozone the solution:

- *Removal of corrosive chlorides in nitric acid recovery following atomic fuel extraction.*
- *Oxidant for rocket fuels.*
- *Chemical synthesis reactions demanding specificity and purity in the oxidant.*
- *Removal of cyanide or phenol from wastes.*
- *Oxidation of oleic to azelaic and pelargonic acids (replaces chromic acid.)*
- *Improving oxidation characteristics of mineral oils.*
- *Elimination of many industrial and sewage odors.*
- *Purification and elimination of undesirable taste, color, and odor in municipal water supplies.*

. . . and a host of new applications still being researched.

If your process calls for an oxidant, it is almost certain that Welsbach ozone will do the job better and at less cost. Why not contact Welsbach.

Write for this booklet on Welsbach Ozone Generation for Industrial Application. Please indicate Company and Title.

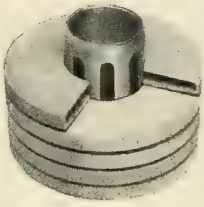
NEW Harmeco PURAFLO FILTERS



Pneumatic Type for Compressible Gases—Pressures to 6,000 lbs.

Harmeco PURAFLO Filters are available in various case designs to suit any piping requirement for filtering helium, nitrogen and other compressible gases at porosity ratings of 2, 5, 10, 20 or 40 microns or coarser. Interchangeable multi-tube sintered stainless steel wire wound elements or strainers are optional. Case is carbon steel forging; stainless steel, monel or other materials as specified.

ELEMENT MANIFOLD PIPE ASSEMBLY

Double tapered one piece Harmeco hollow sintered bronze disc elements provide deep uniform, dependable filtration. Spacing between the discs is uniform when assemblies are stacked and sealed in ported manifold pipe. One piece element design eliminates slip fits or organic bonding materials. The double tapered, hollow disc design prevents blocking off of surface area due to possible cocking of the elements on the manifold pipe. Result: greater filtering area; uniform porosity control; clean decontaminated products.

Luther C. Ringer has been named production manager at Narmco Mfg. Co.

Dr. Robert B. Costello has been appointed assistant manager of the materials department at Aerophysics Development Corp.

Directing Exide's new missile applications department will be **Rear Adm. W. H. Ashford** (USN, Ret.) and **G. S. Hartman.** Missile engineering manager will be **H. A. Fuggiti,** while **J. J. Sullivan** continues as missile production manager.

John R. Townsend was appointed special assistant to the Assistant Secretary of Defense for Research and Engineering. He will also serve as the director of the Office of Fuels, Materials and Ordnance.

Joseph O'Reilly is the new general manager of the Ferroxcube Corp. of America.

Fischer & Porter Co. has announced the appointment of **Edward H. Muhleisen** as manager, aircraft and missile industry division.

International Business Machines Corp. has appointed **Horace W. Thue** director of manufacturing planning. He was formerly manager of the missile and commercial aircraft division at Douglas Aircraft Co.

Everett M. Patterson has been elected president of the Bulova Research and Development Laboratories, Inc. He was also elected to the board of directors.

Philco Corp. has appointed the following scientists to manage various phases of its government and industrial division: **J. Forrest Bigelow,** radar and radio systems; **F. J. Bingley,** audio-video data systems; **C. P. Woodward,** missiles and advanced tactical systems; and **Ralph Deutsch,** fundamental techniques.

John T. Gorham, formerly with the Secret Service and agent in charge of the White House detail, has been named manager of the industrial security department for Bell Aircraft Corp.

Robert G. Clark has been appointed vice president and treasurer of Epasco Inc., manufacturers of electronic data control equipment and systems.

RCA's electron tube division has appointed **C. J. Hollatz** manager of commercial operations.

Douglas C. Vest has been named director of research and development for Redel Inc. He was formerly in charge of applied interior ballistic research, Aberdeen Proving Ground, Maryland.

Robert A. Lehman has been appointed executive vice president, general manager and a member of the board of American Electronics, Inc.

Robert W. Olson has been named vice president, research and engineering, of Texas Instruments Inc. and **E. O. Vetter** as general manager of TI's industrial instrumentation division.

John T. Castles has been appointed

sales manager for the silicone products department of the General Electric Co. Formerly manager of rubber market development, Mr. Castles succeeds **Jerome T. Coe** who has become the department's marketing manager.

Robert M. Fritz has been appointed marketing manager for the General Electric Co.'s missile and ordnance systems department.

Chance Vought Aircraft, Inc. has promoted **Kelly G. Smith** to quality control manager and **George Gasper** to chief tool engineer.

Laurence E. Russell has been appointed director of marketing for the organic chemicals division, Olin Mathieson Chemical Corp.

M. B. Jobe has been appointed manager of customer relations of Goodyear Aircraft Corp. where he will supervise all customer relations division heads.

Richard D. Evans has been appointed as government sales manager for the Special Tube Operations of Sylvania Electric Products, Inc., where he had been special sales representative for the company's semiconductor division.

Edwin S. Hoffman has joined Stavid Engineering, Inc., as contract representative in the firm's Washington, D.C. office.

ELECTRONICS EDITOR
for
MISSILES AND ROCKETS

MISSILES & ROCKETS is seeking an additional electronics editor for its new **Missile Electronics** section. Applicant must be experienced and outstanding technical writer/reporter. Knowledge of electronics and missile fields essential. Engineering background preferred. Please give salary requirement. Write:

ROBERT H. WOOD, Editorial Director,
American Aviation Publications
1001 Vermont Avenue Northwest
Washington 5, D.C.

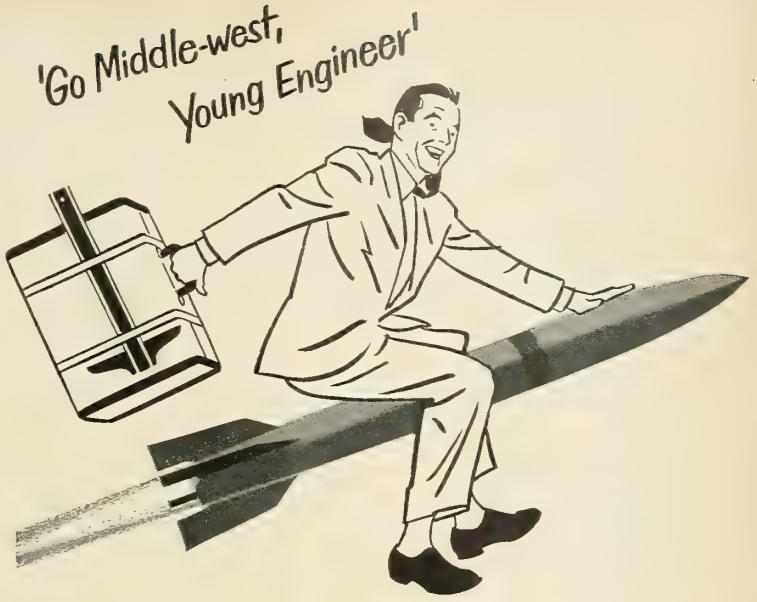
STATEMENT REQUIRED BY THE ACT OF AUGUST 24, 1912, AS AMENDED BY THE ACTS OF MARCH 3, 1933, AND JULY 2, 1946 (Title 39, United States Code, Section 233) SHOWING THE OWNERSHIP, MANAGEMENT, AND CIRCULATION OF

MISSILES AND ROCKETS, published monthly at Harrisburg, Pennsylvania, for November, 1957.

1. The names and addresses of the publisher, editor, executive editor, and business manager are: Publisher, Wayne W. Parrish, Washington, D. C.; Editor, Wayne W. Parrish, Washington, D. C.; Executive Editor, Erik R. Bergaust, Washington, D. C.; Business Manager, Leonard Eiserer, Washington, D. C.

2. The owner is: American Aviation Publications, Inc., 1001 Vermont Ave., N.W., Washington 5, D. C.; Wayne W. Parrish, President, Washington, D. C.; Albert H. Stackpole, Vice-President, Harrisburg, Penna.; E. J. Stackpole, Director, Harrisburg, Penna.; Leonard Eiserer, Exec. Vice-President and Secretary-Treasurer, Washington, D. C.; Eric Bramley, Vice-President, Washington, D. C.; Robert R. Parrish, Vice-President, Chicago, Ill.

3. The known bondholders, mortgagees, and other security holders owning or holding 1 percent or more of total amount of bonds, mortgages, or other securities are: None.



4. Paragraphs 2 and 3 include, in cases where the stockholders or security holder appears upon the books of the company as trustee or in any other fiduciary relation, the name of the person or corporation for whom such trustee is acting; also the statements in the two paragraphs show the affiant's full knowledge and belief as to the circumstances and conditions under which stockholders and security holders who do not appear upon the books of the company as trustees hold stock and securities in a capacity other than that of a bona fide owner.

5. The average number of copies of each issue of this publication sold or distributed through the mails or otherwise to paid subscribers during the 12 months preceding the date shown above was: 11,872

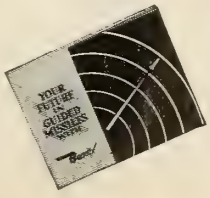
LEONARD EISERER,
(Signature of business manager)

Sworn to and subscribed before me this 11th day of October, 1957.

HELEN M. DES PREZ,
Notary Public.
(My commission expires November 30, 1961)

FOR THE FINEST JOB OPPORTUNITIES IN THE GUIDED MISSILE FIELD!

Yes, it's a fact. At Bendix Guided Missiles you'll enjoy living in an attractive community convenient to metropolitan areas and recreational centers, with experiencing job opportunities unrivalled in the guided missile industry.



As prime contractor for the vitally important Talos Missile, Bendix engineers are engaged in the widest possible range of missile work and enjoy unusual advancement opportunities.

There is no question about it—guided missile engineering is definitely the newest and most modern business, and, logically, the best future for engineers is working with a prime contractor on one of the nation's most important missile projects.

So that you may investigate thoroughly the many advantages of becoming a Bendix Guided Missile engineer, we have prepared a thirty-six-page booklet giving the detailed story of the function of the various engineering groups, such as ram-jet propulsion and hydraulics, guidance, telemetering, steering intelligence, component evaluation, missile testing, environmental testing, test equipment design, system analysis, reliability, and other important engineering operations.

If you'd like to combine the advantages of living in the Middle West and an unparalleled chance for professional growth with one of the world's foremost missile builders, just mail the coupon today for your copy of the booklet "Your Future in Guided Missiles".

Bendix—prime contractor for the TALOS MISSILES

Bendix Products Division—Missiles
412 N, Bendix Drive, South Bend, Indiana

Gentlemen: I would like more information concerning opportunities in guided missiles. Please send me the booklet "Your Future In Guided Missiles".

SUBSCRIBER SERVICE

For additional information about any product or service advertised or mentioned in the editorial pages of this issue of Missiles and Rockets:

Use the attached prepaid reply cards. Circle numbers shown on the reply card that correspond with numbers appearing beneath items described. If no circle number accompanies the article or advertisement, give page number (and advertiser's name) on line provided at bottom of the card.

Your requests for information will be forwarded promptly to the companies concerned.

NEW PRODUCT BRIEFS

RANSPORTER. Liquid oxygen and ni-rogen transporter featuring a new ype of undercarriage. The unit is being uilt in sizes up to 2500-gallon capacity. lofman Laboratories.
ircle No. 250 on Subscriber Service Card.

:OMPONENTS OVEN. Specifically de-gned for components such as capaci-ors, resistors and transistors. Oven ca-ity measures 1" in diameter by 2" length. Temperature regulation is =3°C over an ambient range of 55°C to 100°C. Available in either lug-in or stud mountings. Bulova Watch -o.
ircle No. 251 on Subscriber Service Card.

EMPERATURE ACCELERATION INDI-ATOR. Device warns of excessive tem-erature rise in rotating machinery. Ly-oming Div., Avco Mfg. Corp.
rcle No. 252 on Subscriber Service Card

AUGE PROTECTOR. An adjustable auge protector designed to limit max-ium pressure on air or oil gauges has een developed. The protector auto-atically cuts off flow to the gauge henever system pressure exceeds the ring setting of the device. It reopens itomatically when pressure drops below e cutout point. Superior Hydraulics.
rcle No. 253 on Subscriber Service Card.

ABLE SPLICER. New method of splic-g single and multi-conductor shielded bles uses standard, inexpensive parts make compact, flexible, high-conduc-ity splices with electrical and physical operties comparable to those of the ble. Burndy Corp.
rcle No. 254 on Subscriber Service Card.

OLDERING AIDS. Designed for nted circuits, these miniaturized sol-ring aids have straight or angled tips. ey are useful in connecting or dis-nnecting soldered joints; reaming der from lug holes; probing, scrap-g and cleaning; positioning wires, con-ts and parts. CBS Tube Division.
cle No. 255 on Subscriber Service Card.

ANSISTOR TESTER. An instrument rapid evaluation and testing of NPN d PNP power transistors at their mal operating power has been de-oped by Strand Engineering Co.
cle No. 256 on Subscriber Service Card.

RIABLE SPEED DRIVE. Designed for in process controls or mechanical vo units, this device has infinitely iable speed control in either manual automatic operation. Humphrey, Inc.
cle No. 260 on Subscriber Service Card.

DUPLEXER TUBE. Microwave Associates has developed a 500-kilowatt dual TR tube (bandpass) intended for use with short-slot hybrid couplers. Termed the MA-306B, the new duplexer tube incorporates special design features to sharply reduce arc loss which is 0.6 db at 40 KW peak power.
Circle No. 263 on Subscriber Service Card.

DIP-SOLDERING PRINTED CIRCUITS. Automatic dip-soldering of printed circuit boards is now practical through the use of ceramic dip-soldering fixtures. The product is suitable for temperatures up to 1065°C, will not warp, and molten solders will not adere to it. Technion Design & Mfg. Co.
Circle No. 264 on Subscriber Service Card.

POROUS TEFLON FILTERS. Molded porous teflon filter cups 12" high, 5½" O.D. and 5" I.D. have been produced, with porosity limited to the lower 7" of the product. The filter is rated to remove from suspension essentially all particles over three microns in size. Porous Plastic Filter Co.
Circle No. 265 on Subscriber Service Card.

INERTIA SWITCH. An automatic device actuated by thrusts, impacts or excessive vibrations has been developed by Micro Switch division of Minneapolis-Honeywell.
Circle No. 262 on Subscriber Service Card.

SLM INDICATOR. Both fast and slow transient differential pressures at any two points in a pneumatic or hydraulic system, as well as on an aerodynamic model, can be measured with the SLM differential pressure indicator (Model DPI-114) manufactured by the Kistler Instrument Corp.
Circle No. 261 on Subscriber Service Card.

INFRARED MENISCUS LENSES. Designed to give optimum performance under certain conditions where achromatic imagery is not required, these single-element lenses are designed to have minimum spherical aberration when imaging an object at infinity at a dominant wavelength of 3½ microns. Servo Corp. of America.
Circle No. 257 on Subscriber Service Card.

THERMAL RIBBON. Providing a means of electrically detecting temperatures of the surface to which it is connected, this ribbon is very flexible and has negligible thermal lag. It is less than .020" thick and may be cemented to flat, cylindrical or irregular surfaces. Minco Products, Inc.
Circle No. 258 on Subscriber Service Card.

MISSILE LITERATURE

ELECTRICAL RESINS. A properties chart for electrical resins, giving the mechanical and electrical details of the major Epocast electrical resins used in the industry, has been published by Furane Plastics Inc.
Circle No. 150 on Subscriber Service Card.

ELECTRONIC COOLING. Basic design principles of electronic cooling, covering methods of air convection and metallic conduction, are treated in an 8-page folder published by McLean Engineering Laboratories.
Circle No. 151 on Subscriber Service Card.

THERMAL STRESSES. Said to be the first book on thermal stresses to cover all phases of the design problem of elevated temperatures in supersonic airframes. Material in the book is applicable to nuclear reactors, rocket motors and engines, missile structures and similar designs. McGraw-Hill Book Co.
Circle No. 152 on Subscriber Service Card.

ELECTRON ACCELERATOR. A traveling wave linear electron accelerator, designed for research in nuclear and solid state physics, is described in a brochure offering the machine for sale or lease to physics and electronic laboratories. Applied Radiation Corp.
Circle No. 153 on Subscriber Service Card.

CRYOGENIC ENGINEERING. Sixteen-page booklet published on the Cryogenic Engineering Laboratory of the National Bureau of Standards. U.S. Department of Commerce.
Circle No. 154 on Subscriber Service Card.

ELECTRONIC DESIGN. Booklet published for use by designers of electronic equipment covering design points to be considered. Includes common faults found in equipment, human engineering suggestions and points for proper parts application. U.S. Navy Electronics Laboratory.
Circle No. 155 on Subscriber Service Card.

VACUUM IMPREGNATION. Six-page data publication giving technical information on processes to guarantee pressure tight castings. Cycles for batch and internal pressure impregnation, including simultaneous bonding of dissimilar materials, are outlined and diagrammed, step by step. Western Sealant Co.
Circle No. 156 on Subscriber Service Card.

INSTRUMENTATION TAPES. Magnetic tapes for instrumentation recording are the subject of this illustrated bulletin dealing with six types of tapes for use in telemetering and airborne recording. The bulletin contains charts listing properties and factors to consider in the selection of a tape. Minnesota Mining and Mfg. Co.
Circle No. 157 on Subscriber Service Card.

PORTABLE POWER PACKS. Operation of portable hydraulic power units providing fluid ground power to actuate and replenish hydraulic systems is described in a bulletin issued by Greer Hydraulics, Inc.
Circle No. 158 on Subscriber Service Card.

THERMOCOUPLES AND EXTENSIONS. Chart containing color codes and calibration symbols for thermocouples and their extension wires plus pyrometer wire resistance figures. Thermo Electric Co., Inc.
Circle No. 161 on Subscriber Service Card.

STAINLESS STEEL. A chart for ea identification of government specific tions on stainless steel, including chem cal analysis requirements, specific forms and nearest corresponding SA AISI, and AMS type numbers. Pat A. Frasse & Co., Inc.
Circle No. 167 on Subscriber Service Ca

TITANIUM. Monthly series of "Minu Readers" covering subjects of intere to design engineers. Number one the series deals with prices, to be f lowed by one on availability figur Titanium Metals Corp.
Circle No. 168 on Subscriber Service Ca

HYDRAULIC RESEARCH. This volu was compiled from reports by vario hydraulic and hydrologic laboratories the U.S. and Canada. Each proje is described briefly, and the prese status, results and publications on t project are listed. National Bureau Standards.
Circle No. 169 on Subscriber Service Ca

THERMOCOUPLE GLAND. Illustrat folder shows features of midget therm couple glands, including positive se characteristics, temperature ranges a other information. Conax Corp.
Circle No. 170 on Subscriber Service Ca

HI-TORQUE BOLTS. A 4-page brochu has been published describing t advantages, applications, materia strength characteristics and tools f the hi-torque bolts of Hi-Shear Riv Tool Co.
Circle No. 171 on Subscriber Service Ca

MICROWAVE FERRITE DEVICES. R prints have been made of the bulle on microwave ferrite devices which d scribes phenomena, components a other information regarding the Sperry Gyroscope Co.
Circle No. 172 on Subscriber Service Ca

INSTRUMENTATION CABLES. Deali with cables for telemetering, da recording, circuit-control testing a electronic computers, this illustrated page bulletin gives specifications, col coding data, and other technical i formation. Rome Cable Corp.
Circle No. 173 on Subscriber Service Ca

TITANIUM REPORT. A 202-page ill strated report on titanium and its us in pigments, welding rod coatin ceramics and fibreglass has been issu by the Department of the Interior.
Circle No. 174 on Subscriber Service Ca

PROGRAMMED CENTRIFUGE. D tailed specifications, including electric physical and performance characteristi are presented in a 14-page brochu on a rocket flight simulator. Featur and advantages, typical test runs a data, detailed description and an o lined dimensional drawing are also cluded. The Magnavox Co.
Circle No. 175 on Subscriber Service Ca

INERT ATMOSPHERE GENERATO Bulletin contains flow charts, co analyses, and applications of the in gas system produced by Gas Atmo pheres, Inc.
Circle No. 166 on Subscriber Service Ca

INFRARED DETECTORS. Eight-pa technical data bulletin covering infr red photoconductors and includi graphs and tables on performance. I frared Industries, Inc.
Circle No. 162 on Subscriber Service Ca

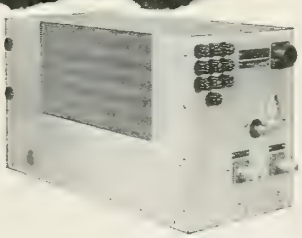
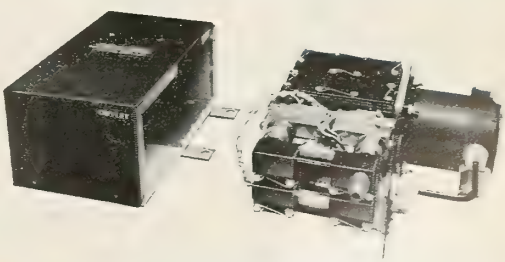
PROTECTING AVIONIC SYSTEMS FROM



JANUS:
protector of doors to heaven

Temperature, Pressure, Moisture, Dust



Expanding aircraft performance creates new problems in protecting electronic equipment under extreme altitude and ambient conditions. Eastern's long experience in the field helps you to recommend electronic gear with confidence that performance will be reliable at temperatures from — 55°C to +55°C; from zero to over 70,000 feet.

Cooling Units, with or without refrigeration cycles, provide safe operating temperature limits in electronic equipment. Pressurization Units that meet government specifications maintain proper operating pressures at various altitudes, and utilize dehydrators that remove moisture and dust from ambient air. A program of research and development continually expands performance ranges to provide customized units to meet your needs.

When your problem is to make your electronic equipment perform efficiently under tough conditions, meet the challenge by asking Eastern for complete and creative engineering help.

Peace is his profession

For more than a decade the officers and airmen of the United States Air Force *Strategic Air Command* have waged *peace* with all the vigor and resolution the military once gave only to war. The survival of our civilization in which freedom of religion, education, art, science and government flourishes, depends today upon the men who are practicing *peace* as a *full-time* profession. In this restless world these professional men are actively dedicated to our way of life!

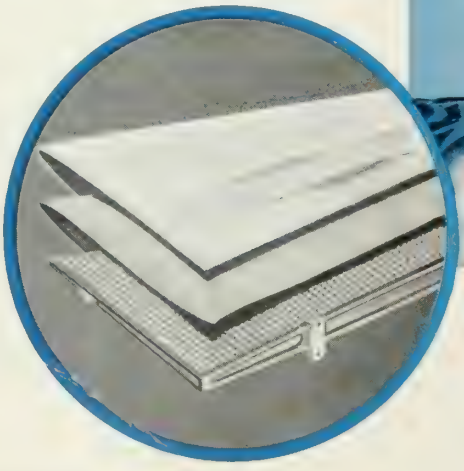
On the Nike Ajax . . . the NARMTAPE® *goes along . . . Not just for the ride!*



Missile engineers at Douglas Aircraft's Santa Monica Division chose bonded Aircomb* sandwich construction for the fins of the Nike Ajax because of Aircomb's superior strength-weight ratios, as well as its basic economy.

However, in selecting the proper adhesive for bonding the fins, several important factors were considered: First, the adhesive must retain its strength under anticipated air friction temperatures. Next, the adhesive must be impervious to temperature extremes, moisture and fungus . . . it was essential that the fins retain their designed load carrying qualities, no matter how, where, or for how long the missiles might be stored. Other important factors: ease of fabrication and uniformity of bonding.

Tests showed Narmtape® tops in every requirement. Narmtape's superior strength/temperature characteristics were more than adequate for the entire temperature range anticipated, and its moisture and fungus-resistant qualities were best in every way. Narmtape's even distribution of adhesive throughout the cotton supporting cloth was a distinct improvement over results attained by hand spraying, and was readily adaptable to volume production methods.

Narmtape is one of a family of outstanding adhesives developed by Narmco to achieve optimum performance in bonded sandwich structures. Facing a sandwich, laminate, or metal bonding problem? Let Narmco adhesives help point the way to an economical, performance-tested solution.

ASCOP

Type AE Sampling Switch

The ASCOP Type AE multi-channel rotary sampling switch is designed specifically for airborne telemetering applications where precision high-speed sampling with the utmost reliability is necessary for accurate data. These rugged instruments are engineered to withstand the most severe environmental conditions. Because the switches provide a low generated thermal noise and a low contact resistance, millivolt signals may be fed through and then amplified with minimum error.

Specification Ranges

Pin and Wiper Arrangement:	1 to 7 poles. 30 to 60 pins/pole. In non-shorting applications alternate pins must "float", therefore 60 pins develop 30 non-shorting channels. 55 to 98% on time with non-shorting channels. 25 to 70% unshorted time with shorting channels. ± 5% phasing pole to pole.
Electrical:	20 microvolts generated thermal noise when sampling 40 millivolt signal and feeding into 250,000 ohms. 2 to 30 ohms contact resistance, maximum. 1 to 1000 megohms leakage resistance pin to pin. 2 to 20 micromicrofarads capacitance pin to pin. 2 to 15 watts maximum signal capacity (purely resistive.) No contact bounce.
Motor:	6, 12, 27.5 VDC governed, 60 or 400 cps 1 phase or 3 phase. ½, 1, 2½, 5, 10 and 30 rps switching speeds. ±5% speed regulation on governed DC units.
Environmental:	−55° C. to 85° C. ambient temperature range, +125° C. for ½ hour. 0-2000 cycles at 20 G's vibration, ½ hour sweep in each plane. 150 G's shock bi-directional in each of three planes (non-operative.) 100 G's continuous acceleration bi-directional in each of three planes. 0-200,000 feet altitude for ½ hour.
Life:	300 to 2,000 hours life, depending on speed, severity of environmental conditions, driving source and quality of switching required.

TIME

CompuDyne® Control

speeds research, development, production testing of missiles and rockets

In the race against time, CompuDyne Control is playing an important role in aircraft, missile and rocket development.

CompuDyne Control is available in a series of highly specialized, dynamic control systems. They are capable of programming severe ramp changes in even a complex group of test variables such as temperatures, pressures and flows of gases and liquids in tremendous or tiny volumes. Or, CompuDyne Control is capable of maintaining stabilized conditions despite the most severe transients.

Over two hundred CompuDyne Control installations are in operation. They include control of test facilities such as dynamic structural loading, engine performance, missile accessory, hot fuel flow, supersonic and hypersonic wind tunnels and dynamic environmental chambers.

Application of CompuDyne Control Systems is based on analog simulation of the systems and the test process. All systems are furnished on a guaranteed performance basis.

CompuDyne Control is a trade-name of cdc control services, inc.

Write or wire for informative 24-page bulletin entitled, "Valid Data . . . economically produced." Ask for Bulletin G-102.

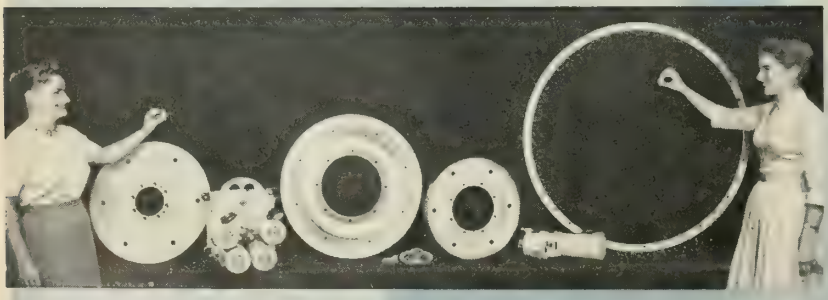
NOW IT CAN BE TOLD!

Western Gear Develops Control Gearing for Nike Missile Tracking Antenna!



Four motor powered gear drive

The control gears and actuators provided by Western Gear for the U.S Army tracker installations have for years provided nothing less than 100% reliability. In the intervening years Western Gear's engineering skill has moved forward with substantial progress in devising systems of advanced tracking techniques which will be "Tomorrow's Headline Story."

Western Gear's painstaking craftsmanship and technical production skill make us the logical source for the design and manufacture of missile components and complete systems . . . and blending of tomorrow's electronic marvels with the experience gained in 69 years of leadership in the mechanical power transmission field.

Here are the Western Gear control gears and actuators used in the missile tracking radar . . . some the size of your finger nail, some 4 feet in diameter.

All respond instantly, accurately regardless of weather conditions, WITH 100% RELIABILITY!

Let's Listen to the Wise Men

At this particularly critical time in national affairs it is appropriate to analyze what the prophets of science have told us, to analyze the reasons why we paid them so little heed, and vow that our mistakes of the past will not be perpetuated.

The list of scientific and educational leaders who have warned, advised and pleaded with our military, legislative and executive planners for a change in direction is endless. Mere reflection on our woes—investigations, more reports, more committees—is not the answer. Such proceedings are very costly and, if mainly politically motivated, tend only to confuse the basic issues.

Certain names stand out. Dr. Hagen asked top priority for *Vanguard,* but his request went unheeded. Dr. Wernher von Braun has time and time again stressed the impossibility of maintaining the valuable research teams when forced to subscribe to wild variations in budget and personnel policy.

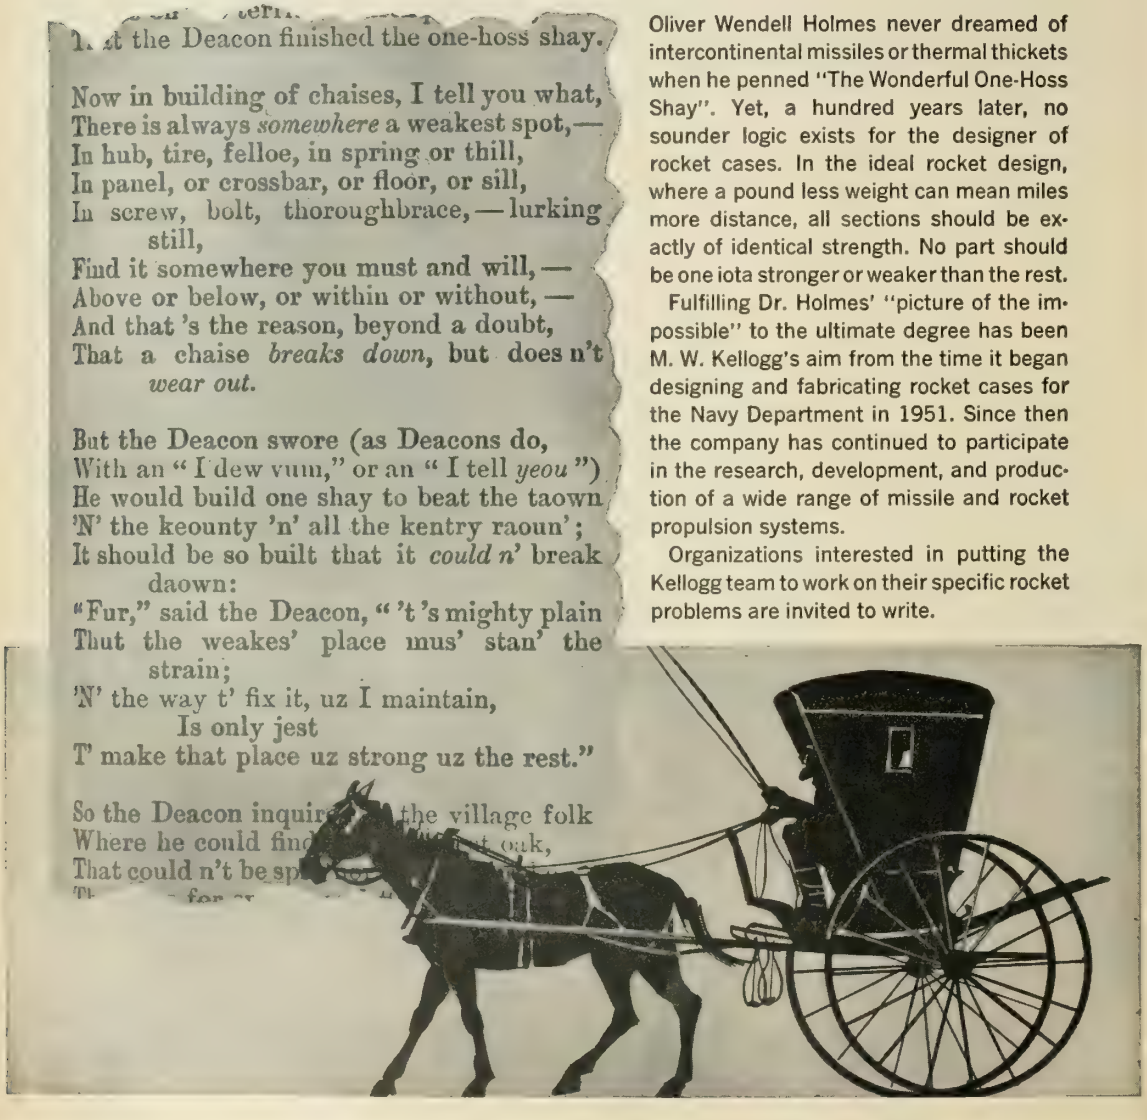
Reports were written by Dr. Louis Ridenour urging a divorcement of research from engineering management. Unsolicited recommendations by the score have been made by men of the stature of Vannevar Bush. Driven to frustration, capable Trevor Gardner simply decided to quit.

These warnings and recommendations are not new. Of great significance now are the prophesies of Dr. Theodore von Kármán, written in 1945 at the request of the late "Hap" Arnold. Von Kármán's report clearly cited the following needs: research training of officers, assignment at top staff level of officers with science training, a large budget apportionment for research in the basic sciences, changes in the military personnel rotation system, removal of scientists from under civil service personnel management, early emphasis, not on the development of hardware then in being, but on ramjets, exotic forms of propulsion, aerodynamics at high Mach numbers, rocketry and the unmanned missile for delivery of nuclear weapons.

Dr. von Kármán's prognosis was frighteningly accurate. He recognized that no long-range program could succeed unless the proper climate and conditions for its success were provided. We have not provided this climate. We have failed to recognize the challenge of Soviet science.

Let us now analyze the basic resistance to the continually urged programs. Let's do something about them. We know that procurement of science by current regulations is poor. We know we are losing trained government personnel. We know we have neglected the support of research and education. We know we have overinvested in wrong facilities.

We have been told this time and time again. We have been warned. We have investigated. Now let's listen carefully to our scientists and our planners, and, if nothing else, take action on the obvious problems which can be remedied now.



Finally, let us not forget that the wise men have told us over and over again that teachers' salaries have for many years lagged behind those of other fields. This is a grass-roots community problem which must be solved and is dependent on the general will of the public.

There is a decline in high school mathematics and science courses in this country. These courses are largely elective in American schools. There are no electives in the Russian high school system. The Russian student is basically trained to serve the State. If the State has need for more persons in a given field, the field is expanded to provide a sufficient number of people.

This is not Russia, thank God, but in the long run—without a sober change in our national thinking about what our priorities in national effort should be—we must eventually face losing the race to a nation far less complacent than we, just as intelligent, and whose youth is driven harder to the task of study and given the tools with which to work.

ERIK BERGAUST

Rocket Logic in Retrospect

...t the Deacon finished the one-hoss shay.

Now in building of chaises, I tell you what,
There is always *somewhere* a weakest spot,—
In hub, tire, felloe, in spring or thill,
In panel, or crossbar, or floor, or sill,
In screw, bolt, thoroughbrace, — lurking still,
Find it somewhere you must and will, —
Above or below, or within or without, —
And that 's the reason, beyond a doubt,
That a chaise *breaks down*, but does n't *wear out*.

But the Deacon swore (as Deacons do,
With an " I dew vum," or an " I tell *yeou* ")
He would build one shay to beat the taown
'N' the keounty 'n' all the kentry raoun';
It should be so built that it *could n'* break daown:
"Fur," said the Deacon, " 't 's mighty plain
Thut the weakes' place mus' stan' the strain;
'N' the way t' fix it, uz I maintain,
Is only jest
T' make that place uz strong uz the rest."

So the Deacon inquir... the village folk
Where he could find... oak,
That could n't be sp...
Th... for ...

Oliver Wendell Holmes never dreamed of intercontinental missiles or thermal thickets when he penned "The Wonderful One-Hoss Shay". Yet, a hundred years later, no sounder logic exists for the designer of rocket cases. In the ideal rocket design, where a pound less weight can mean miles more distance, all sections should be exactly of identical strength. No part should be one iota stronger or weaker than the rest.

Fulfilling Dr. Holmes' "picture of the impossible" to the ultimate degree has been M. W. Kellogg's aim from the time it began designing and fabricating rocket cases for the Navy Department in 1951. Since then the company has continued to participate in the research, development, and production of a wide range of missile and rocket propulsion systems.

Organizations interested in putting the Kellogg team to work on their specific rocket problems are invited to write.

NATIONAL NORTHERN

...newest AP&CC division

Dedicated to research, development and production in

rocket power technology

Test a rocket motor's performance at 100,000 feet altitude... determine how extremes of temperature affect explosive and propellant charges... develop igniters of maximum sturdiness and reliability. These are typical activities at National Northern Division, West Hanover, Mass., latest addition to the AMERICAN POTASH family. Here, a qualified staff of scientists and technicians conducts research, development, field testing and production of propellants for rockets and missiles, explosives, pyrotechnics, detonators, igniters, squibs, gas generators, fuzes and other items.

Extreme environmental conditions are simulated in the laboratory or encountered in actual field tests on the firing range at West Hanover or the 1900-acre test range at Halifax, Mass. Here, too, AP&CC will extend its facilities for the investigation and development of TRONA* boron, lithium and perchlorate chemicals in high energy fuels.

For more than ten years National Northern has demonstrated its ability to work in close coordination with others. As an integral part of AMERICAN POTASH & CHEMICAL CORPORATION it is ready to go to work for you!

We invite inquiries leading to research and production contracts.

CEC's 5-752...
The only recorder/reproducer offering complete front access.

standard of the missile range

CEC's MAGNETIC TAPE RECORDER/REPRODUCER

Selected in competitive tests for Air Force and Navy ranges... meets IRIG Specifications...

Simplify your data problems... get instantaneous playback with CEC's new 5-752 RECORDER/REPRODUCER SYSTEM. Handles Analog, PDM, and FM signals... provides up to 14 tape tracks for simultaneous recording and reproduction of separate signals on one-inch tape. Features CEC all-metal surface magnetic heads. Constructed to meet MIL-E-4758A. For complete data, contact your nearby CEC field office, or write for Bulletin CEC 1576–X7.

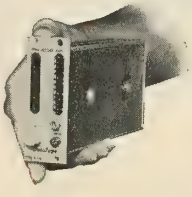
TYPICAL APPLICATIONS

Telemetering from Missiles and aircraft, including FM sub-carrier telemetering • Wind-Tunnel Testing • Jet and Rocket Engine Testing • Studies of Shock and Vibration • Mobile and Stationary Structural Testing: ships, trains, etc. • Static and Dynamic Testing: airframes and components • Sound Measurements: all types of analyses, including sonar, medical research.

DataTape Division

Consolidated Electrodynamics

300 North Sierra Madre Villa, Pasadena 15, California



OFFICES IN PRINCIPAL CITIES THROUGHOUT THE WORLD

For precision in-flight recording, or wherever small size and portability are paramount, DATATAPE RECORDER provides up to 14 tape tracks. This compact recorder provides complete compatibility with the 5-752, guarantees accurate performance under severe environmental conditions (MIL-E-5272A, Proc. 1), and operates at extremely high temperatures to 100°C.

CEC's 1-001 Amplifier Case houses seven record amplifier modules in the smallest package on the market today. Rugged construction provides rigid mounting of modules. Coolant air is provided for operation up to 100°C. Stringent environmental specifications are met without the use of shockmounts.

10-12 oz. Miniature Record Amplifiers feature printed wiring, combination subminiature-tube and transistor circuitry, modular construction, and high-temperature operation to 100°C. Aluminum die-cast packages, 6¼" long by 3¼" high and 1 3/16" wide, provide FM, PDM, and Analog recording.

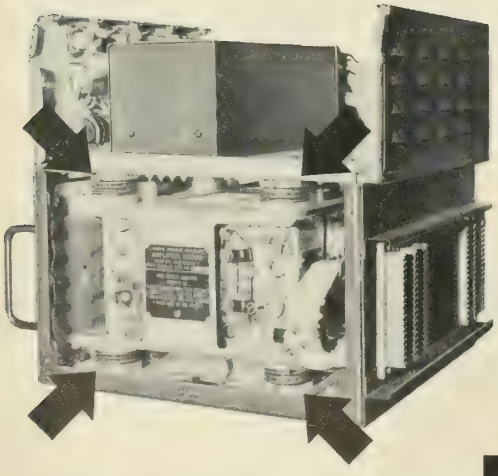
ENGINEERING REPORT



A Case History of Environmental Control

PROBLEM

VIBRATION • SHOCK AND COOLING

POWER TUBE FAILURE during environmental testing of the Servo-Amplifier in the flight stabilization system of Chance Vought's F8U-1 Crusader.

SOLUTION

ENGINEERED MOUNTING SYSTEM:

Robinson Model 1514 all-metal light-weight mounting system to protect entire Servo-Amplifier assembly. Highly damped Met-L-Flex resilient elements are incorporated in an opposed cushioning design. Resulting center-of-gravity suspension system assures all attitude protection for power tube and other electronic components.

The Servo-Amplifier assembly was isolated with no increase in over-all equipment dimensions.

SPECIAL FEATURE:

Range of environmental protection is extended by screened cooling apertures designed as part of the combined chassis and mounting.

PERFORMANCE:

Natural frequency of the mounting system is between 15-21 c.p.s. After 15 G drop tests on all six sides, there was no loss of isolation efficiency which remained as high as 90% at 55 c.p.s. with .060 inches excursion.

RESULT:

1. Increased operational reliability of Chance Vought's supersonic Crusader.
2. Another contribution to the weapons system reliability program pioneered by Chance Vought Aircraft, Inc. in cooperation with Robinson engineers.

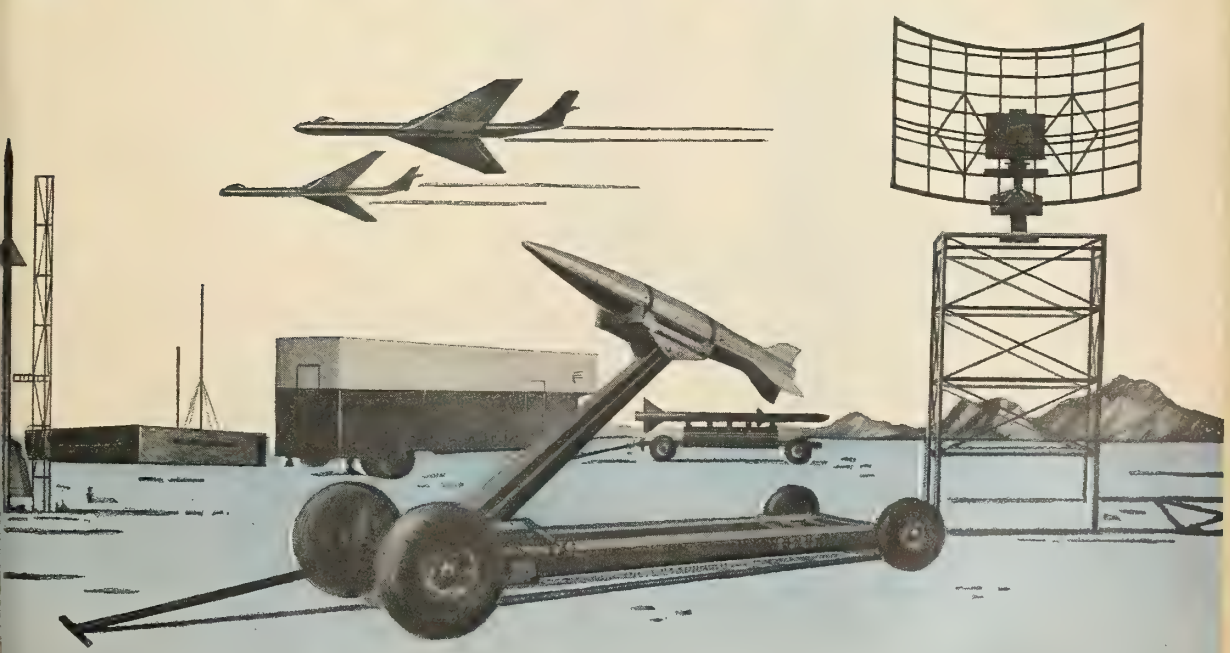
ERCO SUPPORT FOR ALL *Modern* WEAPONS

FROM SPECIALIZED EQUIPMENT TO COMPLETE SUPPORT SYSTEMS

From the smallest critical component to the trailerization of a complete missile test and check-out system — this is the range of ERCO's abilities. Successful projects have been designed both from basic and creative concepts. ERCO engineers have broken with the past in creating products or systems which have fulfilled the national defense need.

A major activity of ERCO's weapon support program is weapon transportation. In this area, ERCO has designed and mass-produced equipment ranging from space saving, highly mobile shipboard dollies, trucks and skids, to versatile and highly specialized transports of larger and more sophisticated construction. Some of these transports carry weapons weighing 12 tons over the most rugged terrain.



Another important phase of ERCO's program is the design and manufacture of complex electronic and electro-mechanical test and check-out equipment as support for missile launching and flight guidance systems.

ERCO — a leading supplier of aircraft simulators, offers its extensive engineering and production facilities and experience to assist you in accelerating the training program vital to the effective introduction of new weapons systems.

If you have the weapon and need the complete support system or highly specialized engineering on separate equipments — write today Dept. MS, Riverdale, Md., for ERCO Weapon Support Brochure and learn how ERCO can help you.

One tape can't serve all recording needs in magnetic instrumentation

There are differences between pulse and carrier recording . . . therefore the tapes used in these systems must have different characteristics. Only in Soundcraft Instrumentation Tapes are these distinct and separate properties engineered into the oxide formulation. Soundcraft then adds two original processes — Uni-Level Coating and Micropolishing — to achieve the surface perfection found exclusively in the most advanced tapes of our time:

Soundcraft Type A Tape for Digital Recording

Soundcraft Type B Tape for Telemetering

Get the Soundcraft Tape that's made for your application . . . get error-free recording!

RCCH oxide formulation gives "Type A" higher signal output and greater retentivity plus unique surface hardness for controlled tape wear rather than uncontrolled equipment wear.

The special FM formulation in "Type B" is a highly refined form of gamma Fe_2O_3 oxide with high temperature binders, lubricants and anti-static agents to assure uniform speed and tape-to-head-contact — preventing flutter.

A REPORT ON THE FIRST SUCCESSFUL PROCESS FOR CHEMICALLY MILLING LIGHT METAL CASTINGS

In high speed jets, rockets, and missiles the price tag on every ounce of excess weight is enormous. Even the use of lightweight aluminum and magnesium alloys wherever possible leaves room for improvement. For while part thickness is often determined by structural requirements, it is frequently a function of the metalworking processes used. Castings, for example, must have sufficient wall thickness to assure sound structure throughout. Thinner sections are generally achieved by machining the parts after casting. This is often an expensive and sometimes impossible task, especially where complex contours or double walls are involved.

Enter Chemical Milling

The first break came when a solution was discovered to the same problem as it affected wrought parts. The solution—familiar to every high school chemistry student—was based on the consumption of metals by powerful reagents. Its successful application to metalworking production presaged significant strides in weight reduction. But when the same techniques were applied to castings, results were extremely poor.

Rolle research immediately began laboratory tests to discover the reason for the failure, and found it often lay *in* the castings. Even minor imperfections in the casting surface unbalanced the process of metal removal—enlarging any defects present. Rolle also found, after much searching, that only certain reagents in certain concentrations—depending on both the part cast and the alloy used—could guarantee success. It has taken almost two years of exhaustive research to refine this process to the extent that it can now take its place as an accepted metalworking technique. Parts can now be designed for casting that could only be constructed by sheet fabrication techniques in the past.

Half The Wall Thickness

The major advantages of this chemical milling process are pretty much wrapped up in the single figure 0.060"—the wall thickness which Rolle can consistently meet by the process. The importance of this figure is readily comprehended by comparing with it the conventional limit on casting wall thickness—.125". Rigid control techniques, developed in the laboratory, even permit an overall improvement in dimensional tolerances of the part as a result of the chemical milling process. And at the same time, surface finishes of an order of 100 microinches or better can be consistently achieved.

There are two ways you can take advantage of this Rolle technique for chemical milling. One requires the controlled removal of metal from the entire surface area of the part. Allowance can be made in the pattern for holding heavy sections and critical dimensions despite chemical metal removal. The other method, useful where the areas to be lightened are relatively limited, requires masking of those areas not to be etched. The proper technique, of course, can only be decided on the basis of the individual part.

Since the success of chemical milling depends to a considerable extent on the soundness of the casting itself, Rolle cannot promise satisfactory results on any but a Rolle cast part. But Rolle will gladly examine your prints and parts in light of this new technique and make recommendations or quote prices, as you desire. Furthermore, we'll be happy to answer any further questions you may have relevant to chemical milling or the sand, permanent mold, shell mold, or investment casting of aluminum or magnesium alloys. Write Rolle Manufacturing Company, 313 Cannon Avenue, Lansdale, Pa., or call ULysses 5-1171.

with the **RW-300**

DIGITAL CONTROL COMPUTER

Wind Tunnels
Engine Test Stands
Environmental Test Facilities
Structural Test Facilities
Guidance and Control System Test Laboratories
Missile and Aircraft Check-Out Facilities
Nuclear Reactor Instrumentation
Data Reduction Centers

Now—at the test site—all major data conversion and computation requirements can be met with the new RW-300 Digital Control Computer. This medium-size digital computer is unique in that it incorporates analog-digital conversion equipment matched to the computer. Thus, the RW-300 can directly monitor measuring instruments, perform complete calculations on the test data, and record the calculated results while the test is in progress. It can also be used as a general-purpose digital computer to perform scientific calculations while tests are not in progress. An RW-300 can free many test facilities from dependence upon computing centers remote from the test site.

Equally important, the RW-300 has versatile control capabilities. With a test routine stored in its magnetic drum memory, the RW-300 can fully control the test facility, utilizing input data as feedback to modify the control actions. The test can be programmed to stop automatically if unsatisfactory or dangerous test conditions develop.

If your organization has a problem in test control, data conversion, or computation, write to: Director of Marketing, Dept. MR-712, The Ramo-Wooldridge Corporation, 5730 Arbor Vitae St., Los Angeles, Calif.

The Ramo-Wooldridge Corporation

5730 ARBOR VITAE STREET, LOS ANGELES 45, CALIFORNIA

Digital techniques employed in the design of the RW-300 computer have also been utilized by R-W systems engineers in the development of special-purpose digital instrumentation systems. Building blocks available for use in such systems include voltage-to-digital converters, electronic commutators, digital data recorders, data-handling links, and special equipment such as the RTD-3103 Range Time Decoder. Additional information on digital instrumentation systems is available on request.

HITCO Insulation Products are designed for MISSILES ...Temperatures up to 5000°F.!

HITCO designs and produces a complete line of High Temperature Insulation Products for the demanding requirements of Missiles and Rockets.

HITCO's THOMPSOglas is a formed High-Density Fiberglas, designed for shock and vibration absorption and thermal protection of instrumentation and missile guidance system components.

REFRASIL High Temperature Laminates and REFRASIL Insulating Blankets are other HITCO contributions to America's Missile Program.

Write or call our Research and Development Engineers for help in solving your special missile insulation problems.

Engineers: Act NOW to move your career years ahead, with the company building the power plants for

ATLAS · THOR · JUPITER · REDSTONE

Even as you read this, ROCKETDYNE is testing the mighty propulsion systems to launch the major missiles of the Free World. There's a unique excitement in the work. It marks a turning point in history. Man is beginning to conquer space.

POWER—AND STILL MORE POWER

At ROCKETDYNE's 1600-acre Propulsion Field Lab. near Los Angeles, and in the new test stands at the Neosho plant in Missouri, the thrust ratings make previous engine development look puny by comparison. And still the demand is for even more power—power that gulps hundredweights of fuel per second—power that must be controlled with the delicate accuracy of a high precision instrument.

NEW WORLD OF ENGINEERING

This is a major new industry. The men who run it are professionals of an entirely new breed. Among them are mechanical and chemical engineers, physicists, dynamics specialists, creators of control systems of all kinds, heat exchange experts, research men, test engineers capable of handling the mightiest engines ever built. Every day two miles of data tape come from the test stands to teach them something new. If the state of their art could be put into print right now, the book would be out of date in a week.

At ROCKETDYNE you'll work with methods and techniques years ahead of conventional industry. You'll be a fully informed partner in major projects. Your advancement will be limited only by your own ability, and our educational refund plan can step up your qualifications for positions right at the top.

YOUR CAREER CAN GROW FAST IN THIS FAST-GROWING FIELD

NORMAN C. REUEL received his BS in Chem. E. at Georgia Tech.. and an MSAE at Cal. Tech. specializing in jet propulsion. Following rocket and radar development in the Navy he joined North American Aviation in 1946 as a research engineer. Now assistant chief of design and development, he also finds time to relax at his ranch home, bowl, golf, and play tournament bridge.

PAUL D. CASTENHOLZ, Pacific combat veteran, graduated B.Sc. (Eng.), UCLA 1949. From research engineer his grasp of rocket engine work raised him through a supervisory post in experimental development to assistant group leader in combustion devices, and then to group leader of experimental engines. Recently completed requirements for his MSc. Relaxes with hi-fi, fishing and back packing.

PYLE *star-line*® CONNECTORS

Assure long-lasting protection of vital connections under a wide range of extreme environmental conditions

Currently establishing itself as a performance leader in the missile systems field, Pyle-Star-Line connectors offer engineers an entirely new line of electrical connectors for universal military and industrial use.

With characteristics of construction and performance never before combined in compact, rugged, lightweight standardized connectors, they exceed NEC requirements and classes A, B, C and E of military specifications MIL C-5015C.

FEATURES

Tough, lightweight shell: Strength comparable to mild steel, yet weighs only ⅓ as much.
Anodic coating: Gives shell toughness of case-hardened steel. Takes up to 1800 volts to penetrate coating.
"Sandwich" insulation: Silicone laminate floats between two rigid discs. Silicone disc absorbs shock, lets contacts align themselves freely; rigid discs impart just the right amount of restraint. Gives all advantages of both flexible and rigid mountings.
Chamber sealing: Silicone insulation disc positively and completely prevents water, gas, moisture or dust from passing into shell.
Wide range of pin and socket configurations: Configurations from 2 to 100 poles available. Within each form size all inserts are interchangeable and reversible.

Environmental Limits of Pyle-Star-Line connectors	
Temperature	—80 F. to 225 F.
Pressure	300 PSI External, 200 PSI Internal
Chemical Resistance	Most acids, most alkalis, oil
Corrosion Resistance	Salt Spray: 300 days without failure
Dust Resistance	Exceed requirements of MIL C-5015C
Shock Resistance	50G Minimum
Vibration	Exceed 20G to Method II of Mil C-5015C
Humidity & Moisture Resistance	Exceed Class E. Spec. of Mil C-5015C
Air Leakage	Meet Class E Spec. of Mil C-5015C

Write today for complete specifications.

letters

M/r Commended for Open Letter to President

To the Editor:

The letter, published on the same day as the report of work by Soviet scientists on a "photonnic" drive, focuses attention on the work that must be done by scientists here in the United States if we are to resume our lead.

Your proposal for a Secretary of Science is very interesting, and, if placed above political squabbles, could accomplish a great deal. A Secretary of Science could, for example, if given sufficient power, cut through a great deal of red tape, and decide, as you bring out so aptly, which of our mssiles to develop.

A point which you did not touch on is education of our youngsters. As long as Soviet education stresses the mathematical and physical sciences from elementary school onward, and our educational systems allows a great proportion of our students to get by with the minimum in these sciences, we cannot look forward to a steady and continuous flow of the young scientific talent that we need. Even if we should institute a "crash program," if we do not continue to develop scientific talent, the program will of necessity die down.

The letter is a great service to the public, and a copy should be sent to each Senator and Congressman.

I. A. Rothstein
1891 E. 7th St.
Brooklyn 23, N. Y.

To the Editor:

Bravo! Recommend followup rebuttal to Presidential speech to wake the gullible Gulliver of America. Suggest you ask Americans to mail copy they read to their Congressmen signing it "Me Too."

Schuyler Hamilton
149 East 34th St.
New York, N. Y.

To the Editor:

I was deeply impressed . . . I know the letter has wakened many complacent Americans to a new sense of urgency in advancing our knowledge in the satellite, rocket, and missile fields. For this great service to your country, I heartily congratulate you.

Robert Troy
660 Gibson Ave.
Kingston, Pa.

Congratulations. Magnificent. I fervently hope it gets results and soon.

Carl Friedlander
983 Park Avenue
New York City, N. Y.

To the Editor:

You are to be commended for your views in this matter of most important concern to the U.S.

Harold Moy
71 West 71st St.
New York 23, N. Y.

To the Editor:

It certainly puts the Sputnik-Eisenhower problem in its proper perspective. Congratulations!

James B. Kobak
J. K. Lasser & Co.
1440 Broadway
New York 18, N. Y.

To the Editor:

Congratulations. Constructive criticism most timely. Lethargy and penny-pinching in scentific fields totally indefensible. We could easily become the Communists' richest satellite.

Dena Connery
7714 East Jefferson
Detroit, Mich.

To the Editor:

I can find but one word . . . "Terrific."

Frank C. Beckert
Howard A. Harkavy, Inc.
341 Madison Ave.
New York 17, N. Y.

To the Editor:

I am in complete agreement.

I have taken the liberty to quote you in a letter to Senator Kefauver.

John W. Whitson
120 Cabrini Blvd.
New York, N. Y.

To the Editor:

. . . a distinct public service . . .

Murray W. Greif
Petroleum Solvents Corp.
331 Madison Avenue

Details Wanted

To the Editor:

I would like further details on rocket sleds and rocket propulsion systems . . . as reported in m/r, March 1957.

H. Paddon
2528 Jay Place
Colorado Springs, Colorado

He Should Know

To the Editor:

Our heartiest congratulations. Your open letter to the President . . . was read in full by Bob Sigrist of Station WENR in Chicago. I fervently trust and hope the President will give your letter full consideration. I am sure that you are being instrumental in formulating our future missile and space policy.

Joe Kauffman, President
Diversey Engineering Co.
Chicago, Illinois

Wants Encyclopedia On Guided Missiles

To the Editor:

Your magazine is excellent and far above any other magazine in this field. I read in your August issue you had reprints of your excellent First Annual Guided Missile Encyclopedia. I would like a reprint.

Allan Gary
317 Shadowmoor Dr.
Decator, Ga.

In the mail.—Ed.

To the Editor:

We enjoyed the information in the Guided Missile Encyclopedia. Since a considerable amount of our interest is in the missile field, I would appreciate it if we could obtain five reprints for distribution to our key personnel.

Dr. Lawrence Gould
Microwave Associates, Inc.
Burlington, Mass.

In the mail.—Ed.

Second in a series,
"Earliest History of Aeronautics"

GENIUS
in the
AGE OF SPECULATION
Leonardo da Vinci, 1452-1519

The contributions to the advancement of early aeronautics made by Leonardo da Vinci were indeed tremendous. With his studies, notes, sketches and experiments he was considerably more than a mere speculator during the "Age of Speculation" in aeronautical history.

Leonardo was the first successful inventor of aerial craft of any kind—the helicopter. His flying models employed a rotating fan, or aerial screw, which became the forerunner of all propeller driven transportation, both aerial and marine.

In 1514, his sketches and aerodynamic notes described a "fall-breaker"—this led to the first successful parachute.

The ornithopter was Leonardo's greatest dream of human flight, but his theory that man could flap bird-like wings and lift himself was unsuccessful. His famous notes and sketches misled many later generations of wing-flapping aerial experimenters, but much credit is given him for keeping the spirit alive in men who sought to conquer the air.

Age of Speculation, 20th Century

Today's study of missiles, satellites and space travel finds us in a new "Age of Speculation." Helping to convert theory into reality is Aerotest Laboratories, the country's leading single source of testing services for the aircraft and missile industry. Aerotest performs complete functional and environmental testing in accordance with all military and commercial specifications.

Beg Pardon

To the Editor:

On receiving my August issue of m/r I was surprised to note on page 84 (under the author's name) that the Jet Propulsion Laboratory was reported located at Huntsville, Ala. We would greatly appreciate a statement in your next issue pointing out that the address should have been Pasadena, Calif. In reality, JPL is affiliated with the California Institute of Technology rather than Redstone Arsenal or the Army Ballistic Missile Agency, although we frequently work closely with these groups on certain programs.

John I. Shafer
Staff Engineer
Jet Propulsion Laboratory
4800 Oak Grove Drive
Pasadena 3, California

Additional Kudos

To the Editor:

I have been reading m/r since its inception, and truthfully state, I have never before encountered so informative a trade publication. To me it is a warehouse of accurate and authentic information. It's content shows a profound editorial insight, rarely, if ever found in a trade journal.

I eagerly await each issue and in view of current federal negotiations, trust it will become the unchallenged bible of the trade.

Frank J. Cunningham
142 Bellmore Road
East Meadow, N.Y.

Information Requested

To the Editor:

A friend and I are planning an exhibit on solid fuel rocket engines for the science fair in our area. I have obtained some information on this subject, but not enough. Could you refer me to any books or magazine articles where I might find something on this subject?

Gaylon Campbell
585 West Fourth North
Logan, Utah

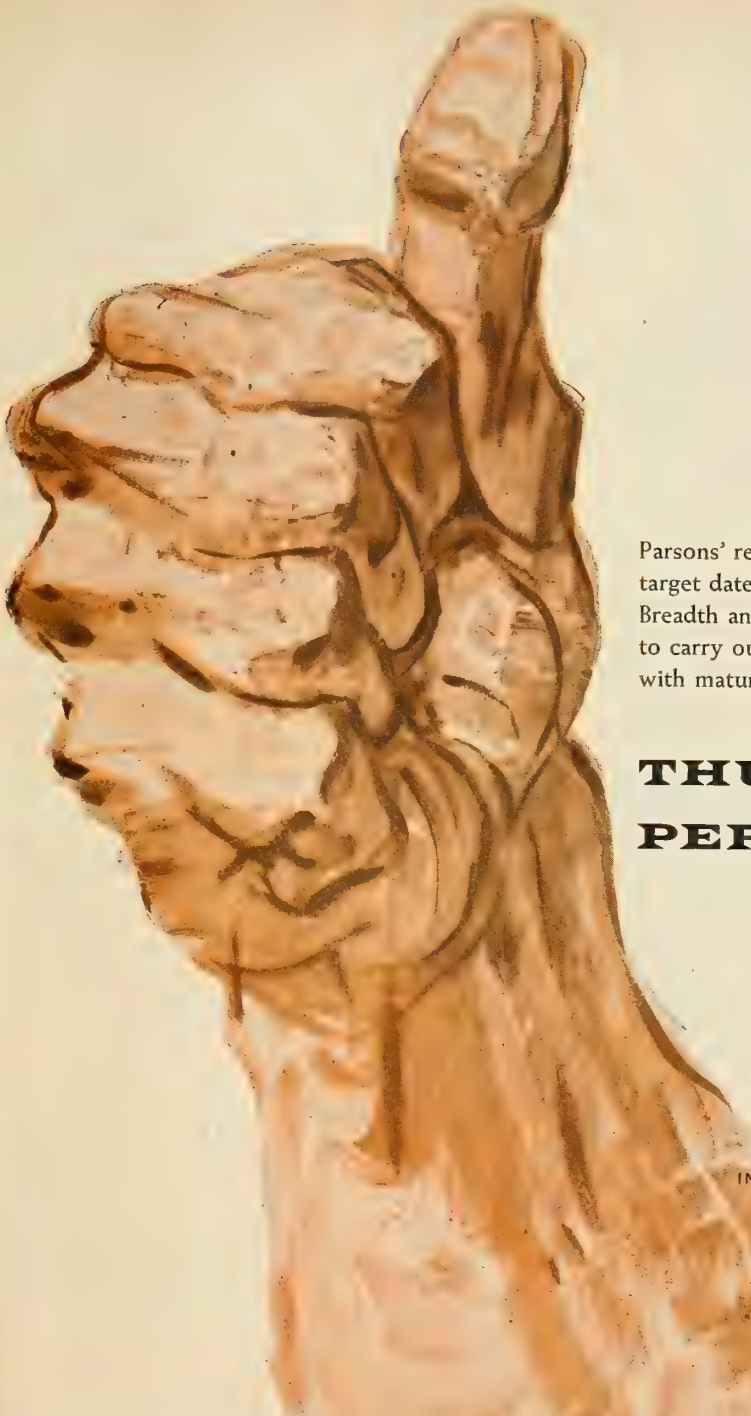
We will forward some details that might be of use to you.—Ed.

To the Editor:

I have been interested in Thorium Ores and Yttrium Oxides and would like to ask of you as to what, if any, part they play in the missiles and rockets.

Danny Bogni
250 Columbus Avenue
Daytona Beach, Florida

Our propulsion editor has an answer for you in the mail.—Ed.



Missile Glossary Needed

To the Editor:

We are frequently asked by students of junior and senior high school grade for a hard and fast explanation of a rocket and a missile. Our impression is that the two words are used more or less interchangeably now, but we ask your advice so that we can pass out authentic explanatory information.

It would help us to know the difference between a rocket and a missile, and between a ballistic missile and manned and unmanned rockets and missiles, space ships, and guided and unguided missiles and rockets. As a matter of fact, probably a glossary of these space age terms

might be well to publish in one of your editions and in that way many other public relations people besides ourselves could become readily acquainted with the precise definition of each term.

From the very name of your publication we assume that there is a distinction and a marked one between a missile and a rocket. Where we become confused is when the terms are used together; for instance, as a missile which is fired into space by means of rockets.

Are we correct, for instance, in saying that a ballistic missile could be an H-bomb located in the nose of a two or three stage rocket and that when it reaches outer space the missile orbits by itself, divorced from the rockets which shot it there? Would it then correctly be termed an orbital ballistic missile, etc.?

Ballistics is said to be the study of the motion of projectiles; a missile is defined in some encyclopedias as something which can be thrown into space; and a rocket is defined as something which is fired under its own power.

More definitive information about all this would certainly be appreciated.

Arthur F. Joy
Public Relations Department
Raytheon Manufacturing Co.
Waltham 54, Mass.

A glossary of missiles, rockets, and space age terms is planned for the near future.—Ed.

Von Braun Reprints

To the Editor:

You have undoubtedly established your magazine as the leader in its field.

To echo another letter to the editor, you have indeed started something in granting m/r cover reprints. I, too, want a color reprint of the July cover of the Bell X-1E. I would also like reprints of Dr. Wernher von Braun's article, "Space Travel and Our Technological Revolution" and the very excellent article by Joseph G. Logan, "New Air for Engineers."

William R. Elliott
3367 Pio Nono Circle
Macon, Ga.

In the mail.—Ed.

To the Editor:

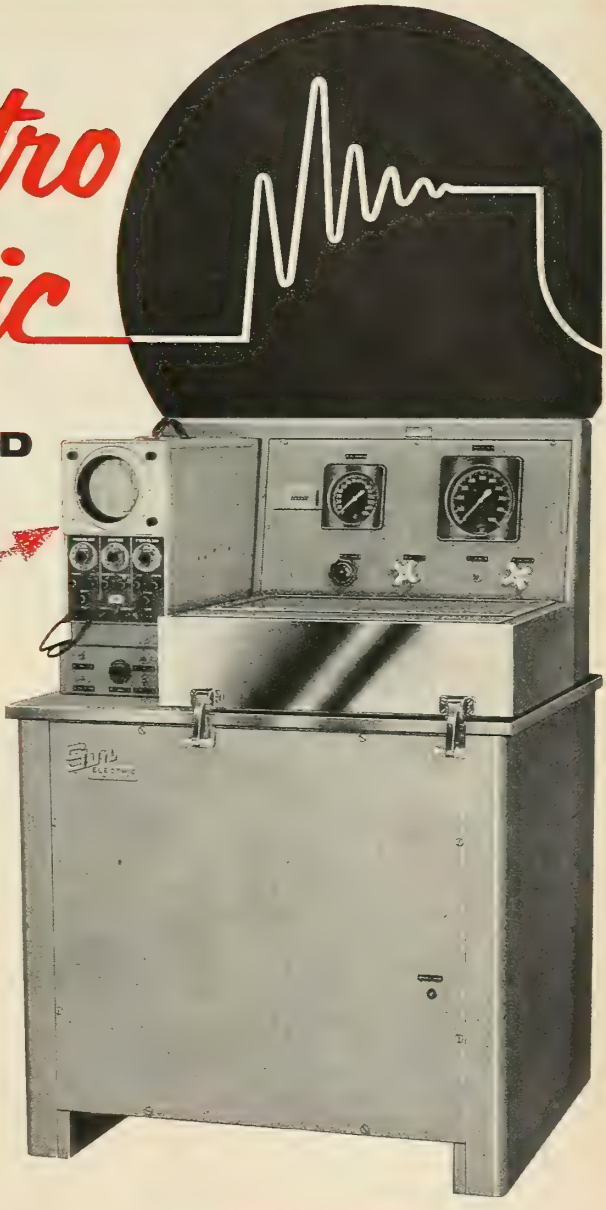
Add my congratulations for your excellent magazine to your growing list. It has filled a great need very admirably.

I would like a copy of Dr. von Braun's "Space Travel and our Technological Revolution." Also a copy of the Guided Missile Encyclopedia, both published in your July 1957 issue. As a recent subscriber, I missed this issue but discovered these articles through my colleagues and our engineering library at Minneapolis-Honeywell's Aero Division.

Reinhold V. Gaertner
5724 West Moore Lake Dr.
Minneapolis 21, Minn.

To the Editor:

I read with deep satisfaction "Space Travel and Our Technological Revolution" by Dr. Wernher von Braun in your July issue. I would appreciate a copy of the special reprint of this article.



May I also take this opportunity to congratulate the entire staff of m/r for the excellence of your publication and especially on the First Annual Engineering Progress issue. It was by far the most comprehensive, informative compilation of such data ever assembled. Keep up

Sun Electro Hydraulic

IMPULSE TEST STAND

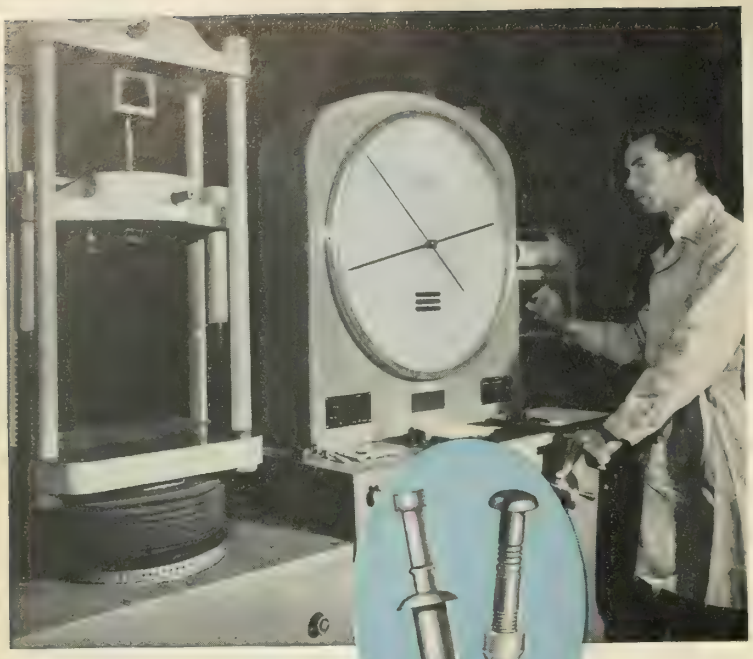
LETS YOU SEE HYDRAULIC COMPONENTS AT WORK

Life and environmental testing of hydraulic components under simulated conditions of pressure and temperature is performed by this test stand—another example of Sun's fine engineering and production skills.

Solenoid valves produce a surge shock condition in the hydraulic component on test. Controlled pulsations through a range of 0 to 100 cpm at pressures to 10,000 psi are displayed as a waveform on a cathode ray oscilloscope. Pressure is stabilized with a nitrogen charged hydraulic accumulator.

Test components are mounted in a safety-glass lidded test chamber equipped with a heater and automatic CO_2 extinguisher to eliminate fire hazard.

Let Sun help solve **YOUR** testing problems . . . write or phone today.



SPECIFICATIONS
Model SX-89 Impulse Test Stand

Length: 40 in. — Width: 30 in. Height: to table top 36 in. overall: 56 in. Electrical Requirements: 115 volt, 60 cycle A.C. Air Pressure: 55-90 psi. Hydraulic Fluid: Monsanto OS-45. Reservoir Capacity: 2 gallons. Test Chamber Heater: 2000 watts. Test Chamber Fire Extinguisher: CO_2 actuated at 250°F.

Every Step Of The Way . . .

Cherry Research Guides Production Of Better Aircraft Fasteners

Step by step, through more than two-dozen exacting operations, specially selected wire is formed into precise Cherry Blind Rivets and Lockbolts* for use in today's aircraft, missiles and rockets.

At each step in this procedure the guiding hand of the Cherry Research and Development Department is in control. For the engineers in this department devote their time exclusively to the development and production of better aircraft fasteners.

The methods—many of the machines—the quality tests were devised by Cherry Research to give the aircraft industry and the military efficient fastening. In addition, they are supplied in the volume needed to keep production lines moving on schedule. The Santa Ana plant has the highest rivet capacity in the world.

These are reasons why Cherry Rivets and Lockbolts are standard in the aircraft industry—and why they give maximum performance —make possible lower unit costs.

For information on how Cherry fasteners and the tools for installing them can help improve your fastening efficiency, write to Townsend Company, Cherry Rivet Division, P. O. Box 2157-Z, Santa Ana, California.

Reporting IAF Congress

To the Editor:

. . . your article on the last International Astronautical Federation Conference and your editorial "Washington Trends." I want to compliment you on a very complete reporting of the conference and a complete factual editorial highlighting many of the current problems we now face in the missile field.

Bill Timm

1920 Home Ave.
Bronx, N. Y.

Amateur Facilities

To the Editor:

I know of several teenagers here in the East with serious interests in rocketry, myself included, who would like to fire their own rockets. Unfortunately, being teenagers we cannot drive out to the Mojave Desert every time that we want to hold a firing because of the distance involved. Because of this I would like anyone with serious ideas on the subject to write to me.

I would like reprints of Dr. Wernher von Braun's excellent article, "Space Travel and Our Technological Revolution," the Guided Missile Encyclopedia and your beautiful June cover.

How About Inventors?

To the Editor:

What part do you expect the American Inventor to play in the new rocket & missile program?

Do you believe you can get the government or industry to accept the man that MADE the thing and who has something new and practical to offer?

In the past it has been: don't let any new ideas in, and if they do get in, don't pay for them and be sure that the inventor is not around to help or get paid.

German Rocketeers in US/USSR

To the Editor:

For the last two and a half years, I have been collecting detailed information, technical as well as nontechnical, about guided missiles, rockets and its allied subjects. I immensely appreciated Mr. Parrish's foresight, when he started "Missiles & Rockets" last October, although I think starting of this magazine a bit earlier would have greatly increased the tempo of U.S. progress in these fields.

The growing challenge posed by Russia, demonstrated recently by their ability to launch two earth satellites, has brought these obscure subjects to the front pages. It is not my intention to go into the political aspects of the situation; but the very fact that USSR has been able to master these difficult technical fields in relatively short time, shows beyond doubt that they have availed of to their fullest use the talents of the best German wartime rocket experts.

I have for sometime been collecting the names of German rocket and missile scientists working both in USSR and USA but due to very scarce information that is available in newspapers and other magazines, I have not gone far. I'm therefore, writing this letter in the hope that you will be able to give me in detail the names of top German, Russian and American rocket scientists working in USA and USSR mentioning the fields in which they have specialised.

For Extreme Temperatures *Plus* Perfect Seal

MARMAN

CONOSEAL

- HIGH PRESSURE PNEUMATIC SYSTEMS
- LIQUID OXYGEN SYSTEMS
- HYDRAULIC SYSTEMS
- EXHAUST SYSTEMS
- FUEL SYSTEMS

Problems of connecting tubing and ducting of dissimilar metals subject to extreme temperatures can be solved with the new Marman Conoseal Tubing Joint. An all-metal joint, it provides metal gasket compression with the flexibility and sealing qualities formerly obtained only through use of organic seals. The Conoseal Joint withstands linear deflections up to 1/16-inch without sacrificing a perfect seal.

The seal is maintained under extreme pressures and temperatures even on joints with material transitions, in which steel and aluminum alloy plumbing are joined.

The Conoseal Tubing Joint is available in three different operating performance ranges to meet varied applications. Standard sizes from 1" to 12" O.D. tube size, with special sizes designed to your requirements. Write today for full engineering details.

Operating Range	Temperature Range (°F.)	Max. Pressure (3" Size @ 70°F.)
Low	—300 to +750	1300 psig.
Medium	—300 to +1000	3300 psig.
High	—300 to +1600	testing still in progress

A DEPENDABLE SOURCE OF AUXILIARY POWER

A leader in the development of reliable, light-weight, self-contained monofuel auxiliary power systems for guided missiles and piloted high performance aircraft, Kidde now offers its combined engineering talents and precision manufacturing resources to firms interested in advanced applications of auxiliary power systems.

At present, Kidde has available turbine-driven units with horsepower of up to 200. These high speed units are designed to supply accurately regulated power at mean altitudes of 40,000 feet and up. However, they may easily be made environment-free, permitting airframe builders extremely wide latitude in systems design.

As a part of its power system development program, Kidde has gained wide experience with many monopropellants. These include ethylene oxide, hydrazine, hydrogen peroxide and propyl nitrate.

Whatever your present or future auxiliary power requirements, Kidde is ready to develop, test and manufacture equipment which will meet your exact specifications. For full information, write Kidde today.

FIRST GIANT STEP INTO SPACE

Grand Central Rocket Sets Altitude Record in "Operation Far Side"

The Air Force has confirmed that it recently fired a rocket to a height of more than 4,000 miles above the earth's surface. The 1900-lb. research vehicle with its 3½-lb. instrument package was launched from a balloon-supported platform, 20 miles above Eniwetok atoll in the Pacific.

Ten solid propellant rocket engines powered the multi-stage missile on its mission into outer space at a velocity in excess of 17,000 mph. The third stage consisted of a cluster of four Grand Central ARROW II rocket engines, and the fourth and final stage of a single ARROW II.

Because of demonstrated performance and reliability, Grand Central Rocket Co.'s ARROWS were selected by Aeronutronic Systems, Inc., a subsidiary of the Ford Motor Co., to play this prominent role in the Far Side Vehicle.

Grand Central *Rocket Co.*
REDLANDS, CALIFORNIA

Grand Central Rocket Co., with its selected scientists, engineers, and administrators, is constantly engaged in the research, development, and production of solid propellants, solid propellant rocket engines, and component parts to further serve industrial, scientific, and military agencies. Grand Central would like to work with you on your propulsion problems.

ENGINEERS AND SCIENTISTS:
employment inquiries are invited.

Soviet Troops Get New Missiles

Present Red Operational Stockpile Twice as Large as U.S. Arsenal

by Frank G. McGuire

The Soviet Army paraded its missile muscles through Red Square recently and left little doubt that considerable technology backed up the mass of hardware shown. Although exhibiting little but tactical missiles, the Soviets answered any questions that existed about the variety or modernity of their missile arsenal.

The mobility of the missiles was in sharp contrast to the horse-drawn-cart days of World War II, and many of the models obviously fulfill the same missions as American counterparts—even to being quite similar in design. The largest missile shown was the T-1, which one magazine erroneously labeled the IRBM T-2. This T-1 was apparently the "80-foot monster" referred to in preparade press reports from the Soviet capital, although its actual length is much closer to 60 feet.

Design characteristics of the T-1 indicate that it uses a LOX system and is generally similar to the *Redstone*. The T-1 is undoubtedly vertically-launched and is equipped with four small fins for stability. Graphite vanes projecting into the exhaust stream indicate that the Soviets have not made use of the gimballed-motor technique. Range of the T-1, with its 77,000-pound-thrust engine, is about 400 to 600 miles.

Judging by the appearance of large-caliber rocket-launching guns, the Soviets have effectively rendered our atomic cannons obsolete. The atomic cannon, with its 20-mile range, is no match at all for the estimated 120-mile range of these tank-mounted guns. The rocket guns have 70-foot barrels, very small recoil mechanisms, and generally follow the Rheinbote design. The short crane, contrasted with a large missile carrier on one gun chassis, seems to indicate that the missile is loaded in stages. Another model utilized a larger crane, suggesting that a single-stage, solid-fueled rocket is used. As far as is known, there are no American designs of this large size following the Rheinbote idea, but several American companies (Aerojet and Armour) are working on smaller models.

Another impressive missile shown was the T-7A, a solid-propellant rocket with a range of about 25 to 30 miles. The weapon is 25 feet long, about three feet in diameter and is carried into battle on a tank. It is launched vertically.

The large size and weight of the missile, in addition to the clean lines and single motor, hint that the Soviets have mastered the manufacture of large composite grains. The design is distinctively Soviet and seems to incorporate greater punch and mobility than either our *Corporal* or *Sergeant* missiles. It could be submarine-launched without too much modification and may be a prototype model of the *Comet*.

Soviet Missiles

Model	Range (miles)	Length (feet)	Diam.	Mission	Thrust (pounds)	Power Plant	Status	Remarks
M 100A	5	7	10″	AAM	n.a.	n.a.	Operational	Standard USSR air-to-air weapon
T-8	20	n.a.	n.a.	SAM	n.a.	SPR	Operational	In use for several years. Other rockets in this category are the T-6 and the GVAI
M-2	20	25	3′	SAM	n.a.	n.a.	Operational	Similar to ***Nike-Ajax***, but larger
T-5B	25	30	2-3′	SSM	n.a.	n.a.	Operational	Free-flight artillery rocket, much like U.S. ***Honest John***

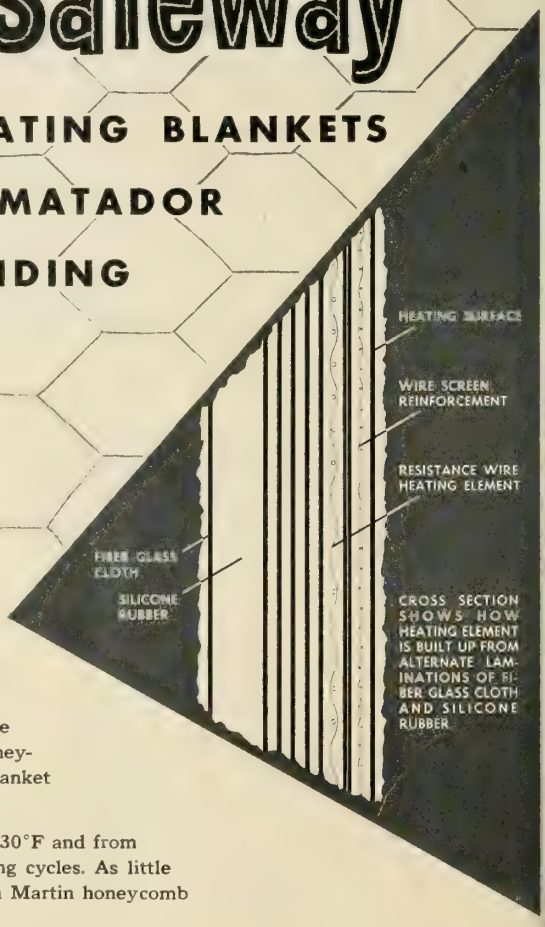
Comet III	100	15	n.a.	ASM	n.a.	SPR	Operational	Radar guided
Comet I	100	n.a.	n.a.	SRBM	n.a.	SPR	Production	May be launched from submarines against land targets
Comet II	600	n.a.	n.a.	MRBM	n.a.	SPR	Production	Same as **Comet** I, above
T-1	400-600	50	5.5′	MRBM	77,000	LPR	Operational	Improved version of German V-2
T-4	1,000	50	5.5′	IRBM	77,000	LPR	Production	Version of T-1, uses wings to glide to target after burnout
T-2	1,800	100	15	IRBM	254,000 77,000	LPR(2)	Operational	Many test flights reported
T-3	5,000	125	n.a.	ICBM	n.a.	LPR	Final Test	Test flights conducted by Red Army
T-4A	12,000	n.a.	n.a.	Skip-Glide Bomber	820,000	LPR	Flight Test	Manned rocket bomber capable of operating at altitudes to 160 miles

n.a., not available; SPR, solid-propellant rocket; LPR, liquid-propellant rocket; AAM, air-to-air missile; SAM, surface-to-air missile; SSM, surface-to-surface missile; ASM, air-to-surface missile; SRBM, short-range ballistic missile; MRBM, medium-range ballistic missile; IRBM, intermediate-range ballistic missile.

A Martin Matador, big as a jet fighter, thunders into the air leaving a blazing trail as it roars toward its 40,000-foot operating altitude.

Safeway



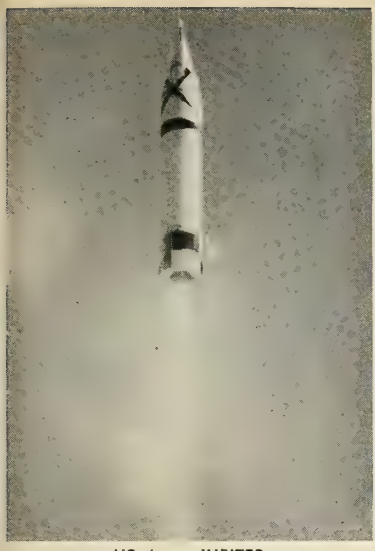
SUPPLIES HEATING BLANKETS FOR MATADOR HONEYCOMB BONDING

The Martin Company, in producing its bonded honeycomb airfoil surfaces for the Matador missile, uses an electric heating blanket which can withstand at least 100 bonding cycles without replacement.

The heating blankets, custom produced by Safeway Heat Elements, can deliver from 400 to as high as 1,200 watts per square foot. They are composed of alternate layers of glass-cloth-reinforced silastic sheets, woven resistance wire heating elements, and copper screening for additional reinforcement and heat diffusion.

The bonding fixture is closed on the airfoil surface and air pressure forces the skin in upon the honeycomb. At the same time, heat built up by the blanket sets up the structural adhesive resin.

The present cure cycle is 30 minutes at 310°-330°F and from 15 up to 100 psi plus preheating and aftercooling cycles. As little as 1 hour, 25 minutes is required to complete a Martin honeycomb structure.



If it has to be heated (and the "it" can be just about anything), you can rely on Safeway engineers to study your problem and — without obligation — submit an appropriate recommendation. *For your copy of a fact-filled folder, write to:*

Safeway HEAT ELEMENTS INC.

680 Newfield Street • Middletown, Connecticut

Circle No. 25 on Subscriber Service Card.

US Army JUPITER
. . . ordered into production by McElroy

Showing some similarity to our *Nike-Ajax* the Soviet M-2 is transportable and launchable from its truck-trailer. It is an AAM, probably an offshoot of the M-1, with shipboard AA defense capabilities. The M-2 does not require a fixed position from which to fire, as does our *Nike* series and may move with battlelines for use in combatting enemy aerial strikes and air reconnaissance. It is considerably larger than our *Nike-Hercules* and *Terrier* missiles and is a trim, two-staged rocket with several areodynamic control surfaces. The large booster-nozzle shows high thrust while the smaller second-stage nozzle indicates a long burning time. It undoubtedly has a range of about 40 miles, altitude capability of 60,000 feet, and is capable of combatting our B-47 and B-52 bombers. Although supporting guidance and control equipment was not seen, the nature of the rocket indicates that the electronic equipment is very probably on a par with ours.

Another new rocket displayed was the T-5B, which bears a striking resemblance to our *Honest John*. It has a similar-size warhead, but the solid-propellant motor is considerably necked down, giving a thin-waisted appearance. The booster motor features 6 canted nozzles.

The powerplant is in two stages, but the small rocket motor and large warhead indicate a support weapon with about a 15-mile range. A considerable number of small artillery rockets for infantry support and flak against low-flying aircraft were also shown in the parade.

The purpose of the show could well have been to impress on the NATO countries that Europe will indeed be swept by an avalanche of Soviet troops should war break out. Their missile mobility and flexibility is undoubtedly aimed at swaying the neutral countries in their determination to remain that way. The overall effect of the parade was to eliminate any doubts that the Soviet Union can handle small wars as well as an all-out effort.

As can be seen from the comparison charts, the Soviets have checkmated the U.S. in all areas of missiles, and in at least two cases (skip bombers and ballistic missile between 250 and 1500 miles range), we have nothing at all. Their infantry support weapons, anti-tank missiles and low-altitude antiaircraft missiles outnumber ours in types and undoubtedly in numbers. However, the figure of 20,000 operational missiles recently quoted for the Soviet IRBM is exaggerated.

USAF THOR
. . . big missile-maker Douglas is ready

The Soviet missiles seem to be supported by more mobile ground support equipment than their U.S. counterparts. A large number of the vehicles attendant to the missiles were tracked for greater cross-country mobility and provisions were made for protection of the crews.

Although there have been claims that Soviet missiles are crude, as is always the claim from this side of the fence, there is little doubt that they are practical, effective and operational. Many of ours are not.

United States Missiles

Model	Range (Miles)	Length (Feet)	Diam.	Mission	Thrust (Pounds)	Power Plant	Status	Remarks

fast fuel transfer

FOR MISSILES

H_2O_2

N_2

Modern Missile technology has developed a vast number of new fuels, each requiring special handling and storage. The problem of safely and quickly transferring these fuels from the storage areas to the missiles is one which requires special equipment. Fast Fuel Transfer systems (FFT), developed by Flight Refueling, Inc., to increase range and payload of airplanes, lend themselves admirably to these new applications.

The experience which Flight Refueling, Inc., has gained in research, design and production of the FFT systems used on modern military aircraft is already being applied to solve the complex problems of split-second preparation of missiles for operational use with greatest safety.

If you have a perplexing missile or aircraft fuel transfer problem, Flight Refueling's engineers will be pleased to discuss it with you and suggest methods of applying the proved FFT principles.

ATTENTION **ENGINEERS**

Unusual career opportunities for engineering personnel are available in new projects for developing new fuel transfer systems. Write Engineering Manager for details.

U.S. Interim Underwater Missile Platform?

A worthy design approach for fleet ballistic missile warfare, which may be receiving top level consideration in light of recent disclosures of Soviet missile submarine might, has been proposed by the Wilford Aircraft Corp. of Merion Station, Pa. The proposal aims to put our fleet in a position of readiness in the shortest possible time. The missile carriers would use available submarine hardware until a substantial fleet of missile-launching submarines has been completed.

Although several broad configurations appear feasible, a design utilizing available submarine hardware as ballistic missile and aircraft carriers is the most promising from the standpoint of time and money. Two World War II type submarines would be lashed together with a detachable hanger-launching pod between them (see drawing). This catamaran-type vessel would be capable of great endurance on the surface or subsurface while carrying fuel, cargo and missiles with complete operational equipment.

Several *Polaris*-type missiles could be carried in a horizontal position inside the hangar. Two launching hatches are shown in the drawing where the missiles could be fired either from the surface or subsurface. Aft opening is hangar door for seaplanes. The hangar door, when open, becomes a landing ramp for bringing the aircraft aboard.

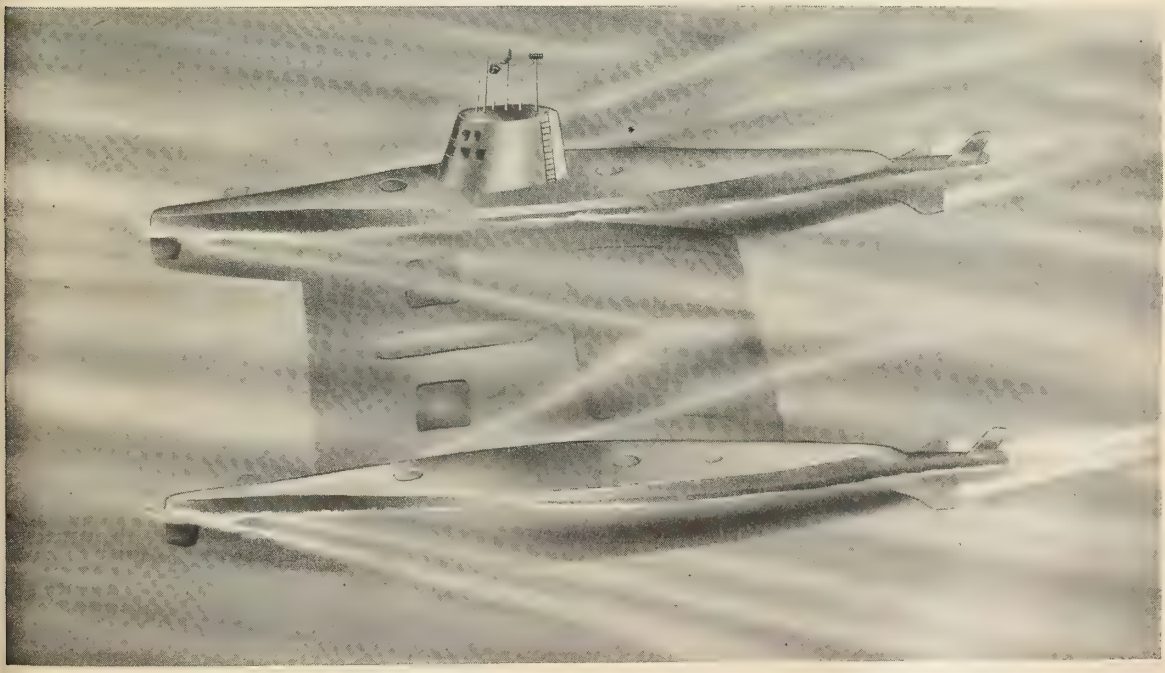
In addition to the ballistic missiles, several other types could be carried by the catamaran submarine, including air-breathing surface-to-surface, surface-to-air and subsurface-to-air. Wilford further emphasizes that the vessel would be ideal for launching manned vertical or near-vertical takeoff aircraft.

The immediate need for missile-launching submarines (the present development schedule indicates that a sizeable missile submarine fleet is years away), was recently voiced by Adm. H. G. Rickover.

"The nuclear-propelled submarine capable of launching intermediate-range ballistic missiles with nuclear warheads could make our Navy an even more effective deterrent force.

"There is no reason why intermediate-range ballistic missiles cannot be launched from floating platforms, surfaced or submerged. The Navy is, in fact, now developing such a missile, the *Polaris*.

"Armed with this missile, the nuclear-powered submarine will become an underwater satellite. It will be large enough to store, maintain and fire intermediate-range ballistic missiles, and it will be able to move anywhere at any time, completely submerged.



"These underwater satellites will launch their attack from far out at sea. They could be placed anywhere within 1500 miles of their targets.

"The problem of locating and destroying such an underseas fleet will be tremendous. Search radar will be helpless against it.

"The underwater satellite marks the closest approach now foreseeable to the ideal mobile platform. It could remain well hidden from the enemy. It would draw the enemy's missile and bombs away from our cities and factories and farms, and draw them toward the uninhabited seas. An aggressor could not escape destruction as long as this missile fleet remained intact. He would be forced to attack it, thus greatly reducing the number of missiles available to him for hitting our territory or that of our allies."

The true significance of the Wilford proposal for utilizing available, soon to become obsolete, submarines was emphasized by Rickover's remarks regarding development time for this entirely new missile system.

"I should make it plain that this weapon cannot be built by the day after tomorrow. It will be a scientific and engineering challenge, comparable in difficulty and magnitude to the first nuclear submarine."

The Wilford proposal would put our underwater ballistic missile fleet in a position of readiness while awaiting completion of nuclear fleet.

where fast response time and maximum performance are essential, where space is at a premium and weight must be rigorously controlled, the special characteristics of Eckel valves are lending themselves to applications and problem solutions never before attainable.

Soviet Space Agency Revealed

The bold accomplishment of satellite flight by the USSR did not spring from short-term intensive effort. Nor was it dependent on scientific breakthroughs, superfuels and metals or new sources of power. The Russian achievements were the product of a coordinated program, planned by a group of competent scientists comprising the Commission on Astronautics of the Academy of Sciences.

This body had the responsibility of organizing the program, assigning the appropriate research tasks and seeing that this work was carried out. Their job was to identify the basic problems which had to be answered before scientific research satellites could be launched and to obtain the answers. They were eminently successful.

These men were not engineers. The tasks of design, production, logistics and launching were left to the military. The controlling body, however, was the Commission on Astronautics.

Vast Science Organization

The Soviet Academy of Sciences is an elite organization composed of hundreds of scientists assisted by practical experts and technicians. Membership to the Academy brings a special stipend and great professional prestige. In essence it is the centralized body of control of all Soviet science. The interests of the Academy range from pure science through engine design to medieval history. In 1952 it had 40 commissions and committees, 14 museums, 4 observatories, 57 institutes, 38 research stations and 15 laboratories. Through these and other agencies it directs the work of thousands of scientists and technicians throughout the Soviet Union. Policy and direction flows from the Council of Ministers through the Chief Scientific Secretary, appointed by the Communist party. The current secretary is A. V. Topchiev. The president of the Academy is a respected organic chemist, A. N. Nesmeyanov.

Because Russian science is under state domination, heavyhanded, unenlightened administration might easily stifle progress and creative talent. Evidence during at least the last few years, however, indicates that great care has been taken not to demand practical results too quickly but rather to assign requirements, responsibility and authority and let the scientists run the show.

The Commission on Astronautics was officially established early in 1955 under the Academy's Astronomical Council. Its official title is the Interdepartmental Commission for the Coordination and Control of Scientific-Theoretical Work in the Field of Organization and Accomplishment of Interplanetary Communication of the Astronomical Council of the Academy of Sciences of the USSR. The fundamental task of the Commission is ". . . to assist in every way the development of scientific-theoretical and practical work in the Soviet Union concerning questions of studying cosmic space and the accomplishment of astronautics."

Responsibilities Spelled Out

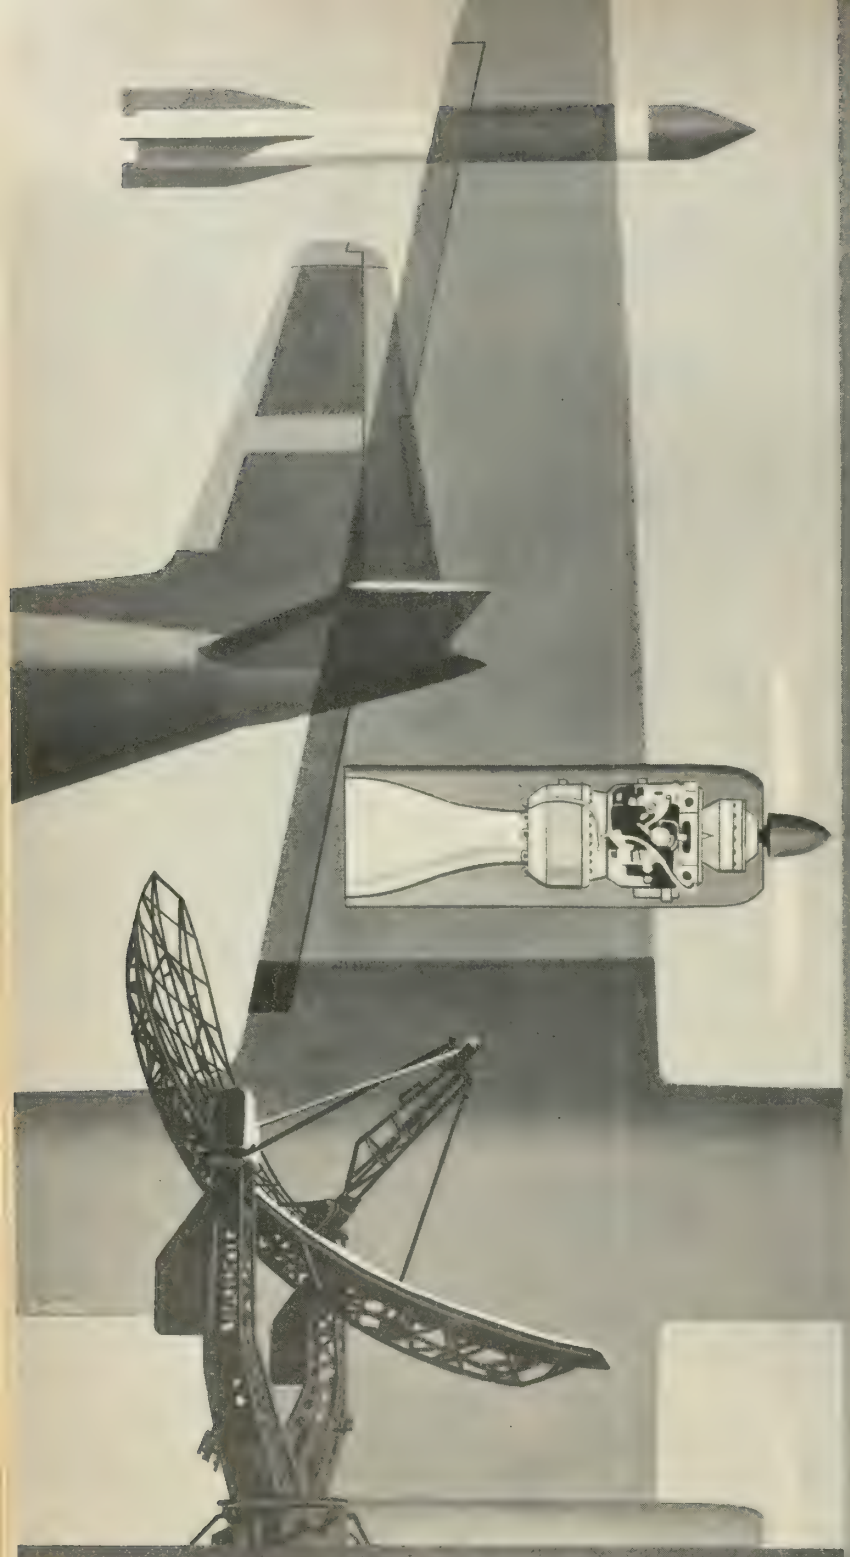
The responsibilities and powers of the Astronautics Commission are specific and extensive. The Commission is charged with:

1) "Taking actions which secure the active participation of academic and branch scientific-research establishments in work for the investigation of cosmic space." (Direct appropriate institutes and laboratories to earmark personnel and time for research on problems assigned by the Commission.)
2) "Organization of work on drawing up problem plans and programs of scientific investigations on the fundamental trends of astronautics." (Draw up a long-range development program and identify the important areas of ignorance to be investigated.)
3) "Broad attraction of scientific-research establishments, of universities and individual investigators to the solution of problems to secure the realization of flight into cosmic space." ("Sell" astronautics as an exciting new field of research to the scientific fraternity.)
4) "Coordination of scientific activities of individual research institutions on the problems of astronautics." (Make certain that there is a "horizontal flow" of appropriate information between the various research institutes.)
5) "Popularization of the tasks and achievements in the field of astronautics." (Educate the population at various levels of intelligence in the technical feasibility of astronautics and

NEW ROCKET POWER

from Petroleum by Phillips

Phillips solid propellants for rockets, made from low cost petrochemicals, come in a wide range of impulses for a variety of applications where required. These new solid propellants can be made relatively smokeless. They operate successfully at temperatures from —75 F to 170 F. Insensitive to detonation by impact or explosion, they are also capable of being stored for long periods without deterioration. Exhaust gases are noncorrosive and relatively low in temperature. The facilities of the Phillips operated Air Force Plant 66, near McGregor, Texas, are completely equipped for development, testing and manufacture of rocket motors. Consult Phillips about *your* propulsion needs.



Phillips 66

We invite you to write and discuss your technical and production problems with us. Or call one of our regional representatives: Washington, D. C.—E. L. Klein, EXecutive 3-3050; Los Angeles—R. O. Gose, GRanite 2-0218; Dayton, Ohio—C. W. Strayer, YOrktown 3263.

Avco makes things better for America

Avco

Avco today

Avco makes things better for America

Avco is a builder of quality products fo the commercial economy and high-performance military systems for natio defense. Gas turbine and reciprocating aircraft engines, electronics systems, fa implements, kitchen components and the Nose Cone for the Air Force Titan Intercontinental Ballistic Missiles are being produced by Avco *today*.

There are many products that identify Avco. All of them display distinguishin characteristics of Avco workmanship . . skill, dependability, resourcefulness. And Avco's first order of business is to make things better for America.

THIS IS AVCO

Avco today is a diversified organizatio whose products include aircraft power plants and structures, electronics for defense and industry, and specialized home and farm equipment.

Avco's divisions and subsidiaries are:

Lycoming—aviation, marine and indus power plants . . . Crosley—electronics systems and aircraft structures . . . Research and Advanced Development . American Kitchens . . . New Idea and Ezee Flow—specialized farm equipmen . . . Crosley Broadcasting Corporation . Moffats Limited (Canada)—commercia gas and heating equipment.

Avco Manufacturing Corporation
420 Lexington Avenue, New York, N

the potential value of satellite and other space research.)

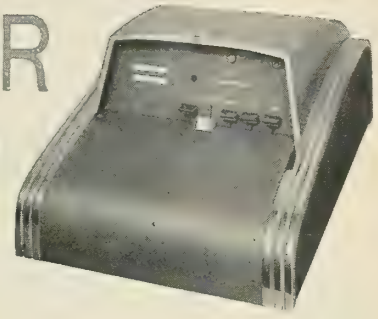
In addition, the Commission shall:

6) Review the plans and reports of the "scientific research institutes which work on the program controlled by the Commission."
7) Sponsor scientific conferences on astronautical problems.
8) Serve as the award committee in stimulating the submission of scientific work in competition for the triennial K. E. Tsiolkowski Gold Medal, established in 1954.
9) Maintain, through the Foreign Section of the Academy of Sciences, contact with the scientific organizations in foreign countries which are concerned with high-altitude research and space flight.

The Chairman of the Commission on Astronautics is Academician L. I. Sedov. Sedov is a distinguished physicist who has been known for his works in analytical mechanics and gas dynamics.

One important announcement may be forthcoming in the next several weeks—the naming of the first recipient of the Tsiolkowski Gold Medal. This award will be made "to Soviet and foreign scientists for original work of major significance in the development of astronautics." The closing date for this competition was 1 April 1957. It could be expected that the individual (or individuals) named will be those who have played key roles in the development of the first *Sputniks*.

With the successful accomplishment of the initial steps in astronautics the Commission on Astronautics is undoubtedly at work on the more obvious follow-up projects—namely, more and larger satellite vehicles, recoverable satellites, space medical research in satellites, lunar impacting vehicle, and circumlunar vehicles.



That these projects are technically feasible is no longer a question. The question is, rather, how far along is the USSR in their prosecution. If they are all accomplished in 1958 the United States will really have a hard time catching up. And a still harder time beating the Soviets to later "firsts" in space research.

Academy of Sciences

The Academy of Sciences of the USSR is the highest central organization which directs the entire scientific and industrial development of the Soviet Russia.

The Academy is divided into a

WHAT WILL "THE ENGINEER'S COMPUTER" DO FOR YOU?

LITTON DIGITAL DIFFERENTIAL ANALYZERS are uniquely personal mathematical tools—which you use yourself at your own desk. The remarkable insight you obtain with these accurate, versatile instruments is an experience reported again and again by mathematicians and engineers. *Insight into the problem* stems partly from your own programming, partly from the continuous rapport you have with the problem as the Litton DDA solves. The Litton DDA plugs into any standard 110-volt outlet. You need only a few hours of coaching from us to grasp the programming for—

Solution of linear and non-linear differential equations including those containing transcendental functions.

Solution of algebraic and differential equations in complex variables, including conformal mapping.

Simulation of non-linear dynamical systems.

Generation of any standard algebraic, trigonometric, or inverse trigonometric function.

Generation of the special functions of mathematical physics which can be expressed as solutions of differential equations. These include the Jacobi Elliptic Functions, Sturm-Liouville Equation, Hypergeometric Function, and Legendre Functions.

Performance of logical switching functions, such as introduction of step functions, ramp functions, limiting, and mode of operation switching.

Multiplication and division of variables, etc., etc.

CAPACITY: Model 20—20 Digital Integrators
Model 40—40 Digital Integrators

ACCURACY: Up to 1 part in 2^{-8} (to 5 decimals)

COST: Model 20, $12,800—Model 40, $16,800.

number of divisions, each of which has further subdivisions. In each of these subdivisions there is a corresponding institute which is constituted of an expert body of specialists, directing the work of laboratories under its cognizance.

The scientific and engineering activities of each industry are also under the direction of the corresponding institute.

The academy has the following scientific divisions: (1) physics-mathematical, (2) chemical, (3) geological-geographical, (4) biological, (5) technical, (6) historical-philosophical, (7) economical and (8) literary and linguistic.

To illustrate the mass of activities under the divisions, following is a breakdown of the activities of divisions (1) and (5):

Physics-Mathematical Sciences

The division of physics-mathematical sciences consists of:

1) Physical Institute (Moscow)

Atomic fission, cosmic rays, physical optics, spectroscopy, radio physics, propogation of electromagnetic waves, radar, acoustics, theoretical physics.

2) Physical-Technical Institute (Leningrad)

Semiconductors, electronics, polymers, physics of nuclei, properties of solids, dielectrics, synthetic rubber, etc.

3) Institute of Crystallography (Moscow)

Pursues a number of practical problems, for example, the use of different crystals such as dielectrics in oscillating circuits which have special features in selectivity, resonance, etc.

4) Mathematical Institute (Moscow)

5) Institute of Geophysics (Moscow)

Origin of the earth, seismology, earth's electric and magnetic fields, winds, cyclones, tides, ocean currents, etc. The institute has numerous laboratories and stations scattered all over the territory of the USSR.

6) Institute of Seismology (Moscow)

A kind of a subsidiary organization of the Institute of Geophysics.

7) Hydrophysical Laboratory (Moscow)

Another ramification of the Institute of Geophysics; study of ocean currents, winds, spectroscopy of ocean noise, means of reducing ocean waves by means of films of oil, propagation of oceanic disturbances in depth, etc.

8) Astronomical Observatory (Pulpovo)

Observation.

9) Institute of Theoretical Astronomy (Leningrad)

Perturbations, astronomical tables and purely theoretical work in celestial mechanics on the basis of data col-

lected by the Astronomical Observatory.

10) Committee on Meteors
Subsidiary of the Institute of Theoretical Astronomy.
11) Laboratory of Astronomical Instruments
12) Laboratory of Radio-Physics and Radio Technique (Moscow)
Short waves, ultrashort waves, nonlinear oscillations, etc.
13) Spectroscopic Laboratory (Moscow)
14) Acoustical Laboratory (Moscow)
15) Committee on Cosmic Rays (Moscow)
16) Committee on History of Physics-Mathematical Sciences
17) Committee on the Development of Physical Methods in Geophysical Research
18) Committee on Astrophysics
19) Committee on Geodesy
Maps, profiles of the sea, soundings, etc.

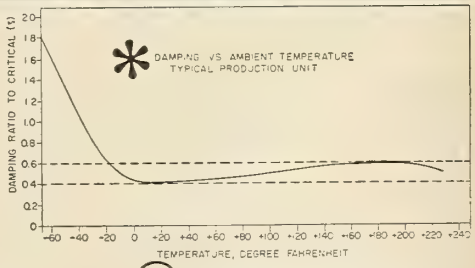
Technical Sciences

1) Institute of Energy (Moscow)
Terrestrial electric field, lightning, production of gas, etc.
2) Institute of Fuels
3) Institute of Metallurgy (Moscow)
4) Institute of Mining (Moscow)
5) Institute of Machine Construction (Moscow)
Theory and construction of machines (jointly with the Institute of Metallurgy)
6) Institute of Mechanics (Moscow)
Stability, gyroscopes, dampers, plasticity, shells, aerodynamics, supersonics, propellers, jet, etc.
7) Institute of Automatics and Telemechanics (Moscow)
Control problems (particularly nonlinear ones), autopilots, etc.
8) Committee on Communications (Moscow)
Steam, diesel and electric locomotives, automatic blocking systems for railroads, traffic control, etc.
9) Committee on Waterways
Construction of canals, waterways, etc.
10) Committee on Radio Communications
Use of short and ultrashort waves propagation, taking into account the nature of the earth's surface, presence of iron ores, etc.
11) Committee on Welding and Electrothermal Devices
Welding, study of stresses in structures, etc.
12) Committee on Standardization

This data was prepared by the m/r editors, based on information from Frederick C. Durant III, L. I. Sedov, chairman of the USSR Commission of Astronautics, and William P. Lear.

Reds Reveal Names of Their Space Dogs

The Soviet team of astronautic dog trainers and observers is reported to be headed by Professor Alexis V. Pokrovsky who is helped by at least five assistants, three of whom are men and two are women. The men are A. Seriapin, E. Yuganov and A. Genin. The women are E. Danich and Z. Voronkova.



Of at least 12 dogs used so far in the space experiments, the following eight are known: Kudriavka (Curly), Koziavka (Tiny), Damka (Little Lady), Malyshka (Little One), Laika (Barking One), Limonchik (Little Lemon), Albina (Whitey) and Linda (a girl's name of Western, not Russian origin).

Until October 12 the dog handling staff referred to Damka as "the champion of height." The Moscow LITERATURNAYA GAZETA, reported she "was the first living being to reach the highest point without a helmet, in the hermetically sealed cabin of a rocket."

The SUBMINIATURE PRECISION RATE GYRO
With Constant Damping Over A Wide Temperature Range *

Check these unusual, high standard specifications

1. Constant damping (0.5 ±0.1 critical from −20° F to +220° F)
2. Subminiature size (0.937" dia. x 2.0" long)
3. Outstanding reliability (exceeds requirements of MIL-E-5272A Specs)
4. High resolution
5. Extremely high natural frequencies (up to 43 cps for 1 radian/sec; lower if desired)
6. Variety of motor characteristics available (3φ, 2φ, or split 1φ; 26V or 6.3V; 400 cps)
7. Wide variety of sensing ranges (from 0.5 radians/sec to 20 radians/sec, full scale)
8. Light weight; 3.7 oz.

MISSILE WEEK

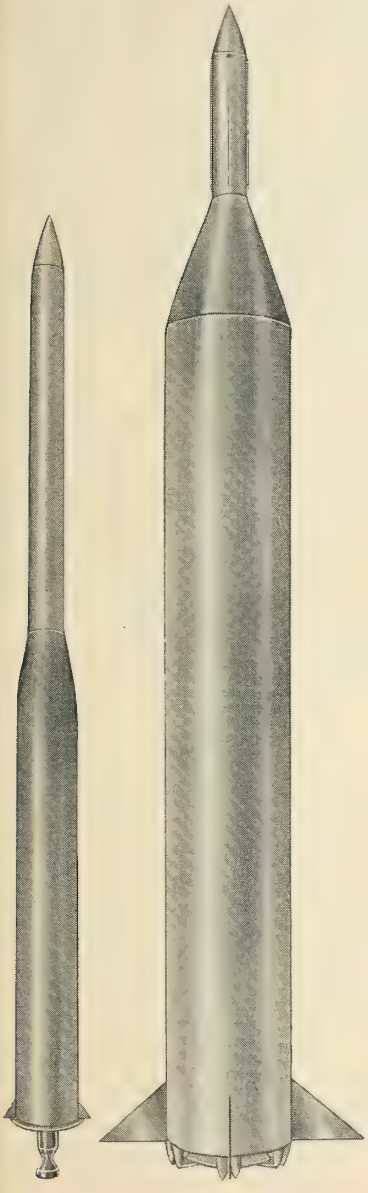
American Aviation Publications, Inc., 1001 Vermont Ave., N. W., Washington 5, D. C.

WAYNE W. PARRISH, *Publisher* ROBERT H. WOOD, *Editorial Director* ERIK BERGAUST, *Executive Editor*

A specialized weekly news service, written by the staff of MISSILES & ROCKETS, the Magazine of World Astronautics.
SUBSCRIPTION RATES: $50 a year, $30 for six months, postpaid. Other rates on request.
APPLICATION FOR REPRODUCTION of material contained herein should be made to the editors.

The Publishers of MISSILES AND ROCKETS magazine announce the publication of MISSILE WEEK.

MISSILE WEEK is a specialized news service designed to keep you closely in touch with everything in the missiles, rockets field and satellite science. It provides information and factual data in advance of general publication and complete weekly coverage of missile developments in Congress, Army, Navy, USAF, and all other government agencies dealing in missile-rocket matters.

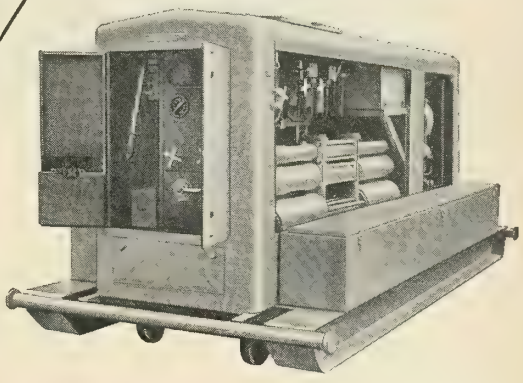


MISSILE WEEK is especially written and designed for the top executives and technical managements in industry and government concerned with the missile and rocket field.

Recent Russian satellite and missile achievements are having a profound effect on decisions in Washington. Events will move very rapidly in the coming weeks and months. These cannot but bear vitally on the future of the entire industry. It is for the purpose of keeping all firms engaged in missile and rocket work informed on these developments that MISSILE WEEK was started.

We will send, upon written request on company letterhead, sample copies of MISSILE WEEK. After a trial period, you will then be invited to subscribe to this specialized service. Subscription rates are: $50 a year, $30 for six months...for U.S.A., Canada. Other rates on request.

For complimentary copies write: Dept. BK, MISSILE WEEK, 1001 Vermont Avenue, Northwest, Washington 5, D. C.



Satellite Carriers: *Vanguard* vs. *Sputnik*

The VANGUARD vehicle (left) will orbit approximately 270 lbs. of satellite (instruments plus empty third stage) at an average altitude of 900 miles. This will require an initial thrust of 100 lbs. for each pound of satellite. The T-2 IRBM SPUTNIK I vehicle (right) launched a total satellite weight of about 1000 lbs. (184 lbs. instruments plus empty T-7A third stage) to an average orbit altitude of 350 miles. SPUTNIK II, essentially a heavier SPUTNIK I with third stage attached, was orbited at an average altitude of 600 miles. Assuming that VANGUARD thrust requirements were met, both SPUTNIKs could have been launched by the T-2 IRBM, which has a thrust of 254,000 lbs.

BURROUGHS RADAR DATA PROCESSING EQUIPMENT

INSURES OUR CONTINENTAL AIR DEFENSE

Warning systems for defense in development today are geared to the instantaneous speed of electronic computation.

As a part of this job, Burroughs radar and infrared data processing equipment is fulfilling vital roles in existing military defense systems (one notable example: SAGE). It is assuming key importance in projected air traffic control systems as well.

Here is one more demonstration of Burroughs' capability and reliability in all facets of defense projects, from research to field service. Areas of our proved competence include electronic computation and data processing, instrumentation, control systems and communications.

We invite further inquiries. Write, call or wire Burroughs Corporation, Defense Contract Organization, Detroit 32, Michigan. Or Burroughs Defense District Offices: Paoli, Pa. • Dayton, Ohio, 3898 Linden Ave. • Encino, Calif., 17071 Ventura Blvd. • Washington, D.C., 1145 19th St. N.W.

Russian Space Savants Active In Egypt

The first Soviet astrophysical expedition in the Middle East has begun its activities in the Aswan (Assuan) region of Egypt. The expedition is headed by Academician V. G. Fesenkov.

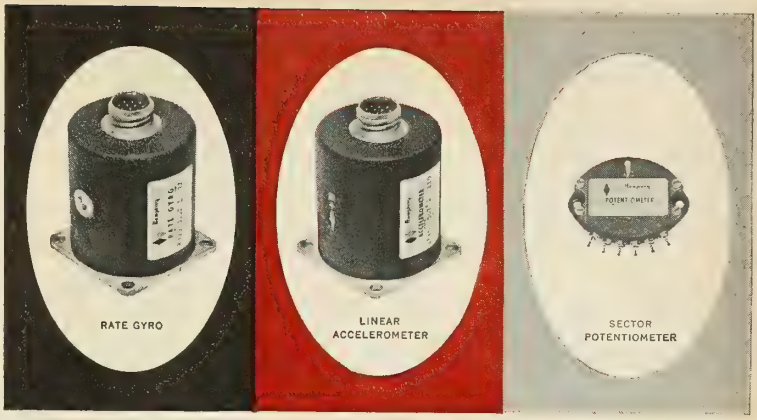
The Cairo correspondent of TASS, the official Soviet news agency, reports that "the local authorities and inhabitants have met the Soviet expedition warmly and are rendering it all the necessary aid in its work." An Egyptian astronomer, Dr. Adli Salama, has joined the Russian group to participate in its research.

Castable Rocket Propellants Described

ESCH, Germany—Speaking before a German rocket society meeting, Dr. Götz von Francois described cast rocket propellants. Essentially thermoplastic, homogeneous propellant materials used are 50% trinitrotoluene, nitrocellulose, diglycol, and stabilizers. Another combination uses 50% trinitrophenyl glycol nitrate, also with nitrocellulose, diglycol and stabilizers. The cast propellants have a temperature range of 0-50°C and are somewhat less smoky than black powder. Rockets weighing 12-14 pounds, have attained ranges of over 20,000 feet.

Missile Association Makes Rapid Progress

The Association of Missile & Rocket Industries (AMRI) is constantly signing up new members and organizing for service.



After the second organization meeting in October, attended by representatives of 48 companies, AMRI was incorporated as a nonprofit association in the District of Columbia.

Under an initial board, headed by Adm. J. A. Briggs of the Research Laboratories, Cook Electric Co., the member companies are consulted as a steering committee pending the election of a larger board and a full slate of officers.

Adm. Briggs stresses the importance of "trade association services to help member companies find their place in the missile program." The industry is being canvassed for opinions both as to the AMRI program and questions of national policy.

Committees are being formed on Program, Membership, By-laws, and Statistics.

Kendall K. Hoyt, Executive Director, is opening a suite of offices for AMRI at 1079 National Press Bldg., Washington 4, D.C.

Advanced Instrumentation by Humphrey

New production inertial sensing instruments for extra precision and reliability

Among the outstanding features of Humphrey's new inertial sensing instruments are: dry helium filled, hermetically sealed steel cases; standardized mountings for rate gyro and linear accelerometer; and choice of regular AN connector or new pigmy connector.

RATE GYRO is of new simplified design, with light-weight efficient motor, accurate trouble-free damping, and choice of inductive or potentiometer pick-off.

LINEAR ACCELEROMETER is of dual contra-rotating mass design. It has practically zero sensitivity to cross acceleration and angular acceleration; ±symmetrical or asymmetrical ranges (0 to 1G) to (0 to 100G).

SECTOR POTENTIOMETER is designed for precision angle measurement in minimum space. Of all-metal construction, it is used extensively in aircraft instrumentation. Resistance element is tapped with three extra connections to provide greater circuit flexibility. Suitable for angles up to 70°. Standard units suitable for operations to 350°F.

Rate Gyro—Model RG15-0102-1: New simplified design with light-weight efficient motor.

Linear Accelerometer—Model LA15-0501-1: Zero sensitivity to cross and angular acceleration.

Sector Potentiometer—Model CP01-0204-1: Cutaway photo shows rugged cast all-metal construction.

Soviets Now Preparing *Sputnik* Telescope To Probe Mars?

Once a *Sputnik* is beyond the limits of the atmosphere Prof. Y. A. Pobedonostsev of Moscow has announced, a telescope installed on such a satellite will magnify objects 10,000 times their size, instead of the 900-times magnification possible with man's earth bound telescopes. From a *Sputnik*, the Russian scientist said, "objects on the moon which have a diameter of only 12 meters" can thus be observed, and the questions on the so-called "canals" on Mars can be answered. In addition, the character of the surface of Mercury, Venus, Jupiter and Saturn can be studied.

Russia Appoints Space Watchers

The Soviet Union's newest and mightiest ionosphere observing station has recently been installed at Voyeikovo in the Leningrad region. It is manned by a staff assigned to the task by the Leningrad Electrotechnical Institute headed by Prof. M. P. Dolukhanov and Candidate of Technical Sciences E. V. Ryzhkov.

A new meteorite-tracing radar installation is now being built at the Astronomical Institute in Ondrjeev, Czechoslovakia.

Ehricke Proposes Astrophysical Decade

Krafft A. Ehricke, assistant to the technical director of Convair Astronautics, has proposed a ten-year space study program, patterned after the current International Geophysical Year for study of the earth's immediate interplanetary environment and preparation for human travel in space. Ehricke suggested 1965-1975 as an appropriate period for this International Astrophysical Decade.

Power to send IAD research vehicles throughout the inner solar system can be achieved with moderate increases in the capabilities of rocket engines now being built for long-range missiles, Ehricke said. He estimated that these "instrumented comets" can be developed in the next five to ten years.

Space research with instrumented comets holds a tremendous technical, scientific, political and cultural potential, Ehricke stated. He said much fundamental information on the nature of nearby interplanetary space can be learned by launching simple, lightweight bodies capable of reflecting

Pneumatic controls

AiResearch is the largest designer and manufacturer of pneumatic controls for the aircraft and associated industries. During the past 10 years more than 300,000 units have been produced and are in service.

Temperatures of the fluids (including gas and liquids) range from −400°F to +2000°F at pressures to +6000 psig. The units operate at any ambient pressure at ambient temperatures from −300°F to over +1000°F. Line diameters range from ⅛ inch to 15 inches.

This equipment is developed and tested in the finest pneumatic facilities in the world. Your inquiries are invited.

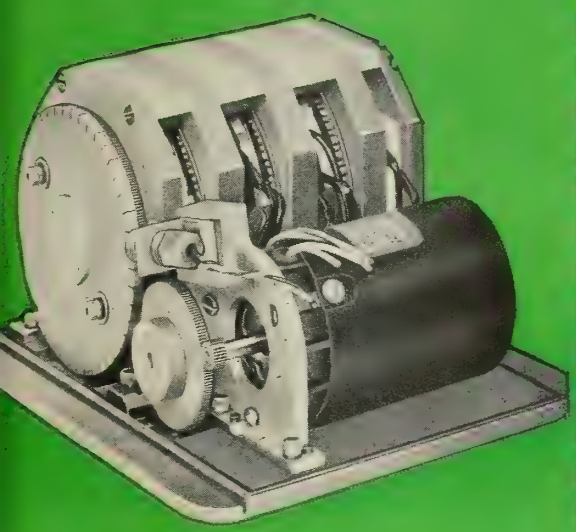
sunlight, carrying telemetering equipment similar to that to be used in the *Vanguard* satellite project, or carrying hydrogen bombs which, upon detonation, would emit a flash that could be studied spectroscopically from the earth.

One such vehicle proposed by Ehricke could explore interplanetary regions at relatively small expenditures of power. This vehicle, a gas-inflated polyester sphere, could be propelled away from the earth by detachable rocket boosters, then accelerated further by radiation pressure from the sun.

Radiation-propelled spheres 500 to 1000 feet in diameter could carry several hundred pounds of instruments. These vehicles would be useful in exploring the distribution and density of interplanetary matter such as comets, meteors, cosmic dust and gas. Their silver, reflective coating would make it possible for astronomers to follow their progress optically.

H-bomb probes of space would require increased propulsion but could yield much information. These vehicles could be fired on a collision course at the Moon, Mars or Venus and the H-bombs set to explode either on impact or above the surface of the target body. Spectroscopic study of the flash could provide data on atmospheric composition.



Princeton and Detroit Universities Study Superperoxide Propellant

It has been learned that studies related to the formation of hydrogen superperoxide, H_2O_4 have been underway for several years at at least two U.S. universities—Princeton and the University of Detroit. The Princeton work is being carried out by J. D. McKinley at the Forrestal Research Center under a chemical kinetics project. The project is headed by Dr. Donald J. Kenney of the missile and rocket section.

The USSR has been attempting to synthesize the potential propellant for at least five years. Latest work may indicate that the superperoxide is not a true compound or polymer of ordinary peroxide but may be free oxygen radicals dissolved in H_2O_2. If the theory is proven true it would mean that free radical solutions might be combined with ordinary oxidants or fuels. In this way hydrogen peroxide or nitric acid with free radicals could give substantially higher performance than liquid fluorine or ozone. It might sound the death knell for the boron exotics since a hydrocarbon fuel could be "spiked" with methyl or ethyl radicals.

ESIGN ACHIEVEMENTS WITH **SUPRAMICA*** ceramoplastic

MYCALEX TM Commutation Switch for Telemetering, Using Precision-molded SUPRAMICA* 555 Ceramo-Plastic Commutator Plates.

Precision-molded SUPRAMICA* 555 Ceramoplastic Commutator Plate, CP-348, With 360 Contacts and 2 Slip Rings. Other Standard Plates Are Available.

OVER 1000 HOURS SATISFACTORY OPERATION AT 1200 RPM

CUSTOMER EVALUATION TESTS DEMONSTRATE RELIABILITY OF MYCALEX TM TELEMETERING SWITCHES

Mycalex* TM commutation switches with SUPRAMICA ceramoplastic commutator plates have introduced a degree of accuracy and sustained dependability never before approached in telemetry. Evaluation tests show **completely satisfactory performance** for more than 5500 hours at 600 rpm, with unattended life in excess of 1000 hours. Exhaustive testing under severe conditions demonstrates consistent noise level performance as low as 0.2% peak-to-peak of signal into a 500 ohm load.

Where warpage of only .0002" of the commutator plate will distort and destroy the value of the signal, these precision switches withstand extremes of temperature, altitude, shock and vibration and deliver a clean, unvarying pulse.

Such accuracy and dependability depend on painstaking precision workmanship, and commutator plates with total dimensional stability. SUPRAMICA ceramoplastics have thermal expansion coefficients comparable to most insert metals, assuring tight bonding and permanent anchorage of contacts. High dielectric strength, radiation and arc resistance, low electrical loss, and thermal endurance as high as 500 degrees C. (932°F.) are also provided. In military and industrial applications, Mycalex TM commutation switches with SUPRAMICA ceramoplastic commutator plates are making significant contributions to the reliability and durability of electronic equipment.
Write for complete technical information.

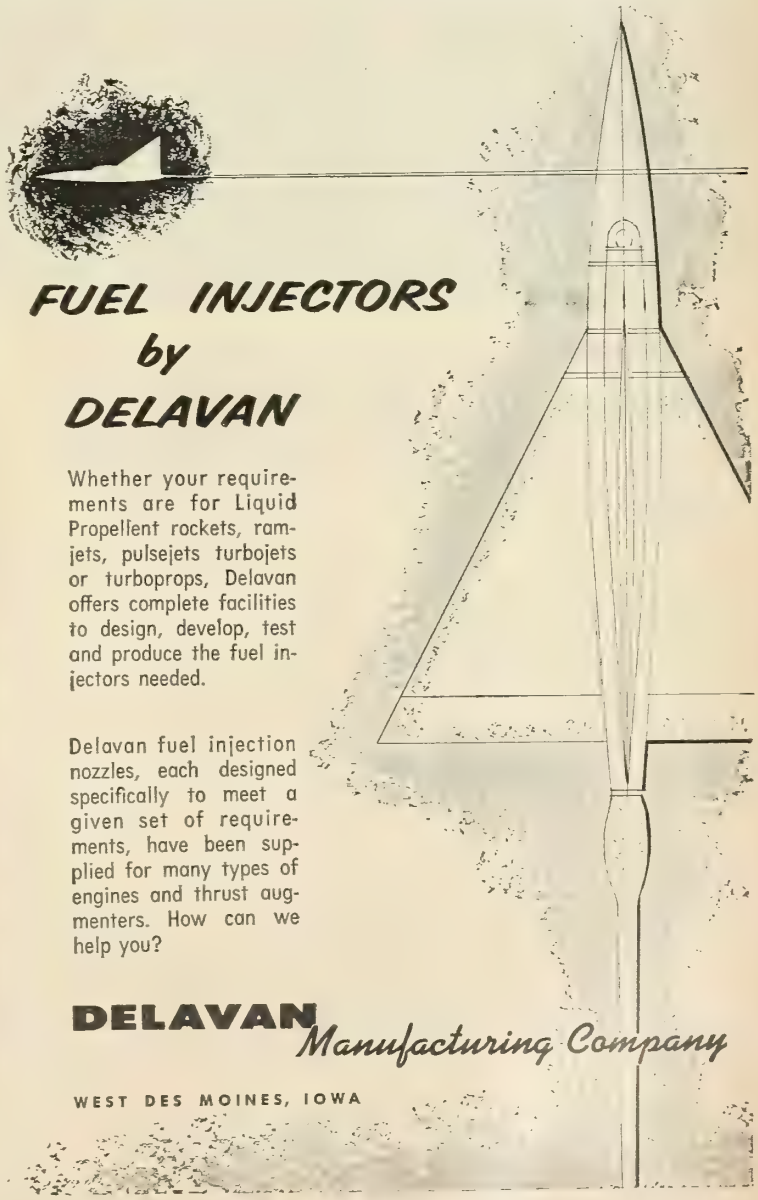
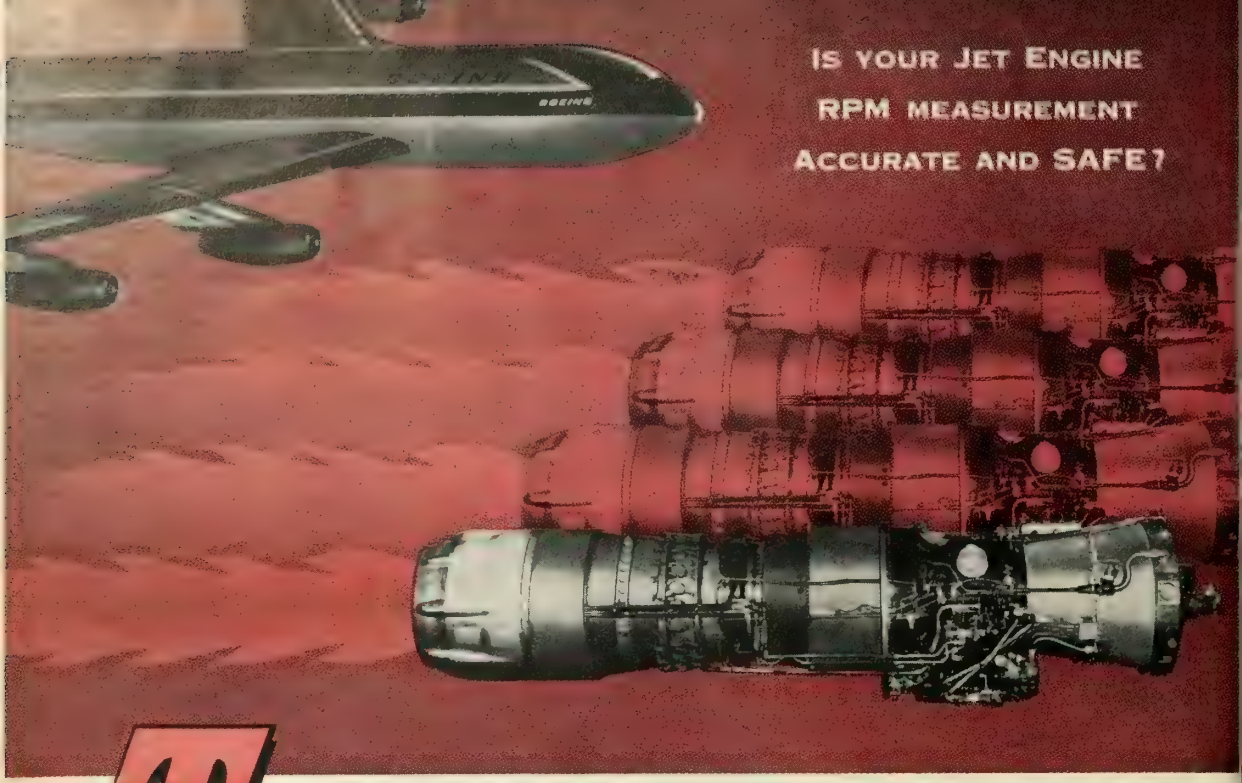
U.S. Army's *Jupiter-C* Becomes Satellite Carrier

The long-awaited decision to place the Army *Jupiter-C* research rocket into the satellite service may not put the United States into space any sooner than was originally planned but it is indicative of a progressive acceptance of the importance of space science. Also, this addition to the U.S. program guarantees only that we will place *a satellite* into an orbit during the IGY.



If *Vanguard* and *Jupiter-C* are both successful, it means that we will have *more* satellites of practically the same weight and for basically the same scientific experiments. No plans have been disclosed for placing larger and more varied instrument carriers into space. In addition early reports indicate that the possibilities of the Army orbiting a satellite before the Navy's *Vanguard* are very slim.

The Navy is confident that its first test satellite, to be launched within a matter of days after m/r goes to press, will be successful. If so, the remainder of the test spheres will be shelved and preparations undertaken to launch the first full-size 20-inch satellite immediately. Dr. Hagan, project director, stated this could happen shortly after January 1st.



Meanwhile the Army has the task of completing and checking out three *Jupiter-C* vehicles that were left over from the successful nose cone re-entry program. Gen. Medaris emphasized that after the rocket vehicle has been delivered to the launching site, at least 30 days are needed to test and check out the launcher before actual firing. The utilization of the military test vehicle as a carrier has imposed a cloak of security on most of the operation. Sifting of the meager information available indicates that pad-

JUPITER-C (left) alongside JUPITER satellite launcher (JUPITER plus three SERGEANTs, second stage, and one SERGEANT, final stage).

IS YOUR JET ENGINE RPM MEASUREMENT ACCURATE AND SAFE?

TAKCAL®

READS JET ENGINE SPEED to GUARANTEED ACCURACY of 10 RPM in 10,000 RPM (±0.1%)

The inter-relation of RPM to efficiency and thrust in jet engines is fundamental. Proper adjustments for maximum thrust, maximum engine life and maximum safety of operation can be made only upon accuracy of instrumentation. The TAKCAL tests to guarantee that accuracy.

The new B & H TAKCAL incorporates a refinement of the frequency meter principle. It operates in the low (0 to 1000 cps) range, reading the frequency of the tachometer generator on a scale calibrated in percent RPM corresponding to the engine's RPM. It reads engine speed while the engine is running with a guaranteed accuracy of ±0.1% in the range of 0 to 110% RPM. Additionally, the TAKCAL circuit can be used to trouble-shoot and isolate errors in the aircraft tachometer system, with the circuit and tachometer paralleled to obtain simultaneous reading.

The TAKCAL's component parts are identical with those used in the J-Model JETCAL Analyzer. They are here assembled as a separate unit tester and for use with all earlier models of the JETCAL Tester.

The TAKCAL operates accurately in all ambient temperatures from –40°F. to 140°F. Low in cost for an instrument of such extreme accuracy, it is adaptable to application in many other fields.

For full information write or wire . . .

CHECKS TACHOMETER "SYSTEM" ACCURACY.
ADAPTS TO ANY FREQUENCY PROBLEM!

Explosion-proof TAKCAL for special applications. Measures 200 to 7500 RPM, direct reading, with ±0.1% accuracy.

readiness of satellite-carrier *Jupiter-C* 1 is still several days away.

Army officials further stated that the 20-pound cylindrical satellites are not ready. Jet Propulsion Laboratory will supply the packages. First satellites will be six inches in diameter and over two feet long. Transmitters will broadcast on 108 mg in order that existing Minitrack stations can be utilized. Three to nine launchings have been planned—all "live." Gen. Medaris expects at least a 90 per cent successful orbit capability.

There have been reports that a change in the propulsion system would be necessary before the *Jupiter-C* would be capable of orbiting a satellite. Army officials stated this might involve nothing more than the addition of a fourth stage. The original *Jupiter-C* nose cone re-entry vehicle reached an altitude of 600 miles, a range of 3600 miles and a speed of about 15,000 mph. A configuration and propulsion change could easily force an agonizing stretchout in the program's schedule.

The *Jupiter-C* vehicle is about 70 feet in length with a maximum diameter of six feet. At least three stages will be lashed together in the final configuration. The *Redstone* 300-mile liquid-propellant rocket will comprise the first stage. A cluster of 11 "scaled-down" *Sergeants* will make up the second stage with a cluster of three of these solid-propellant rockets for the final stage. JPL will supply second- and third-stage rockets. Copper Development and an unknown division of General Motors are fabricating the lash-up components. Chrysler and Reynolds Metals will produce the body of the vehicle.

Second- and third-stage rockets and the guidance system will be enclosed within the 29-foot warhead and control section of the modified *Redstone* first stage.

Snark Hits Target At 5000 Miles

The U.S. Air Force's Northrop *Snark* SM-62 has demonstrated ability to send a nuclear warhead to any target in the world with a 5000-mile flight made under simulated operational conditions.

The *Snark*, launched from the Air Force's Missile Test Center at Cape Canveral, Fla., was programmed to impact a target near Ascension Island in the South Atlantic. The subsonic surface-to-surface missile delivered its payload, a simulated hydrogen warhead, on the target with "unprecedented" accuracy.

IMPORTANT DEVELOPMENTS AT JPL

Teamwork in Missile Development

The Jet Propulsion Laboratory provides a wide range of research and development activities. Projects include problems in the fields of Electronic, Mechanical, Aeronautical, Chemical and Metallurgical Engineering, Physics and Mathematics.

The fluid character of these activities provides a keen incentive to JPL engineers and scientists. These men are given wide latitude and unusual individual responsibility—at the same time working as a thoroughly integrated team on all aspects of entire missile systems rather than on certain highly specialized missile components.

Sweden Shows Its New Missile Designs

Sweden's first guided missile press demonstration, with the exception of some smaller exhibits at a recent defense exposition in Gothenburg, was held in Stockholm on Nov. 4. At Barkarby outside Stockholm, the Air Force showed its newest weapon, the Type 304 air-to-surface missile developed for the Saab-32 *Lansen* transonic all-weather attack aircraft which is now standard equipment with all Swedish Air Force attack units.

The 304 is currently undergoing extensive trials prior to its introduction into service. It is already in limited production. The new missile was developed by the Swedish Guided Weapons Bureau in collaboration with other governmental and civil organizations. Its production is handled by the Air Force's own central workshops and civil subcontractors.

Very little technical information has been revealed on the 304 except that it is rocket-powered and is fitted with an all-weather guidance system. The missile, two of which can be carried by a *Lansen,* was demonstrated both on the ground and in the air. A fly-by of a *Lansen,* carrying two of the approximately 13-foot-long missiles, showed that the reduction in the airplane's speed is not very great.

The 304 is regarded as an extremely important weapon in Sweden's defense against an invasion over the sea. It will enable the *Lansen* units to fire with utmost precision against enemy naval vessels well outside the range of conventional antiaircraft artillery.

In addition to the Air Force 304 missile, a new naval surface-to-surface guided missile, known as the 315 was shown for the first time. The 315 has been designed for use from destroyer-type vessels against other vessels.

The new missile, now undergoing trials at sea, will initially equip the two new destroyers *Smaland* and *Halland.*

Acceleration to flight speed is provided by four built-in booster rockets. For cruising it uses a special type of jet engine, presumably an advanced type of pulse-jet engine. The missile has an all-weather guidance system. The greatest advantage of the new missile is that it permits firing at targets outside the range of conventional artillery. The missile is 26 feet long.

In general, Swedish guided missile development is handled by the Guided Weapons Bureau. In the future, however, new missile projects will be handled by the aircraft industry, notably Saab. The Swedish policy is to develop only such missiles that cannot be purchased abroad. Guided missiles that can be obtained from abroad will be acquired. One type that will certainly be needed is the surface-to-air missile.

Two Type-304 air-to-surface missiles are shown mounted on Saab-32 LANSEN fighter.

Latest addition to the Swedish fleet is the 315 all-weather surface-to-surface missile.

Washington Trends

by Erik Bergaust

PHILLIPS PETROLEUM HAS TEST FIRED AND DELIVERED several solid-propellant rocket motors of over ¼-million lb./sec. total impulse. Much of the work in progress is directed toward high-energy propellants containing ammonium perchlorate. The company's fabrication processes and techniques permit great grain scale-up with the same plant equipment. This column erroneously reported in September that Phillips was not too interested in these high-energy propellants.

SEVERAL CONGRESSMEN WANT TO KNOW WHO IS FOOLING WHO with all this talk about instant retaliation with an ICBM. The LOX-filled *Atlas* takes over two hours to ready for launching. This time probably will never be reduced to less than an hour. Flight time of a Soviet ICBM is about 30 minutes and our ICBM bases will be the first targets. We could instantly retaliate, assuming our bases are not blasted, only with a solid-fueled ICBM already zeroed in.

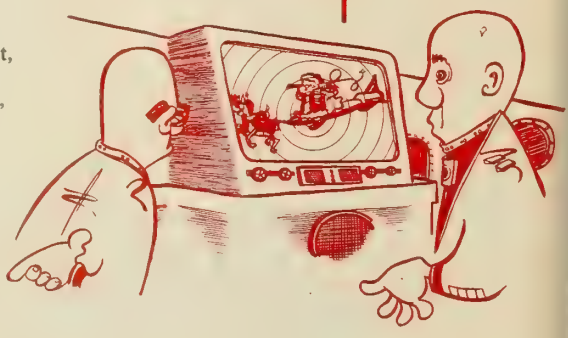
CENTRAL INTELLIGENCE AGENCY REPORTS SHOW that the Soviet fleet is now larger than ours. When is the Navy going to tell the public this? The Soviets are not retiring their capital ships. Their submarine fleet (now nearing 600) is unquestionably a major threat. In addition, many of their surface ships can launch rockets and are protected by antiaircraft missiles.

ONE OF PRESIDENT EISENHOWER'S ADVISERS says the Russians have committed a "colossal blunder" by launching their *Sputniks*. We agree that recent events may have awakened the U.S. before the point of no return was reached, but perhaps Mr. Clarence Randall, author of the statement, would like to explain this "colossal blunder" to the millions of people who know little except that two *Sputniks* are up there. As far as these people are concerned, our six-inch satellite will be a "silly bauble" compared with the Soviet versions. And our 21-pounders will be launched at least six months later, at that.

NOW THE PENTAGON IS WISHING that it had paid more attention to the report that Dr. Theodore von Karman prepared for Gen. Hap Arnold in 1945. The report foresaw many of the problems with which we are now faced. It is particularly significant that the general requested the thoughts of Dr. von Karman on two areas of future planning: what assistance should we give to the educational and commercial scientific organizations during peacetime, and what proportion of available money should be allocated to research and development.

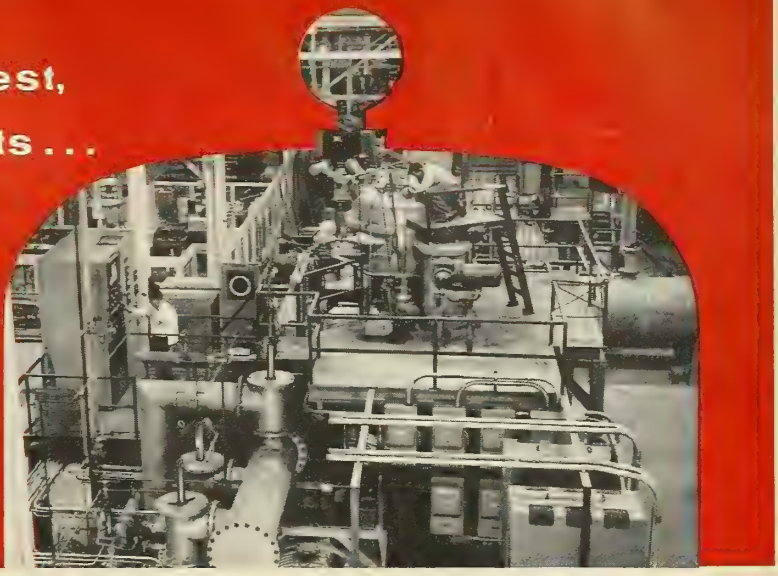
Dr. von Karman's prognosis was frighteningly accurate. "No long-range program can possibly succeed unless the proper climate and conditions for its success are provided." We have not provided this climate and 1) we have failed to beat the Soviet Union in the development of an ICBM; 2) we have failed to launch the first earth satellite; 3) we have failed to launch the first earth satellite with an animal aboard; and 4) we shall fail to beat the USSR to the moon.

A THEORETICAL METHOD OF KILLING ICBMs involves the use of a cylindrically bundled photonic beam. Its spectrum lies primarily in the ultraviolet region and it can deliver up to 80 per cent of its energy to the target, despite having to penetrate the atmosphere by as much as 75 miles. Because the reflection of metal is small in the ultraviolet spectrum, the impinging energy of the ray is transformed into heat which vaporizes the body.

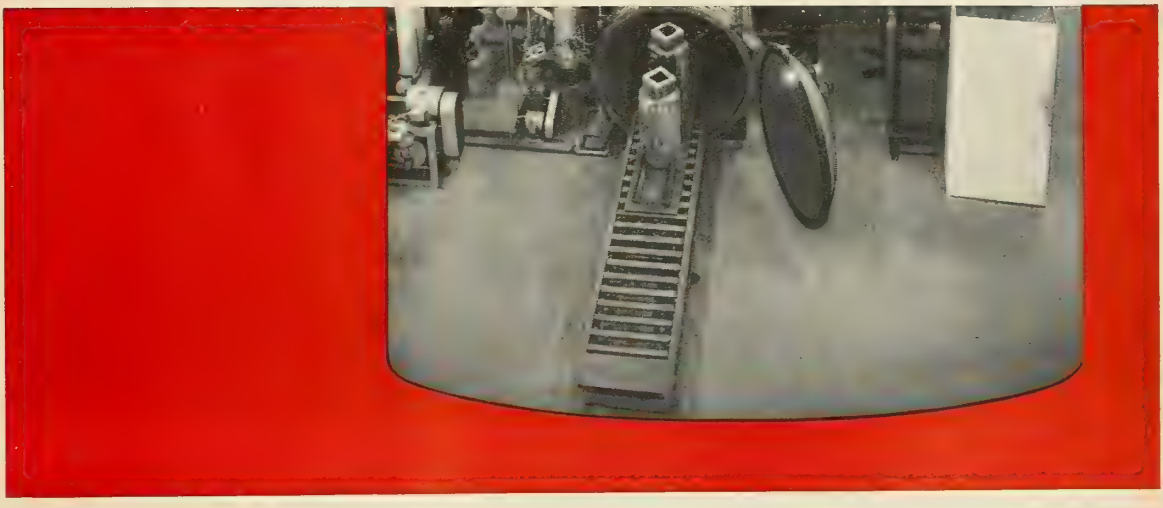


ONE UNUSUALLY WELL-INFORMED CONGRESSMAN wants to know why we don't show the Russians a thing or two by shooting down their *Sputniks*. With what, may I ask?

the flight before Christmas



by Jim Carr



'TWAS the flight before Christmas and through outer space,
Not an object was stirring; support was in place.
The dials were all set in the blockhouse with care,
Checked out were components located there.
Our crew well-secured by a strap in each lap,
The rhythmic countdown had soon caused them to nap.
With the Captain in charge and I on his right,
We blasted away on elliptical flight.
When out in the orbit, there rose such a clatter,
We leaped to our console to check on the matter.
Checked out was each rocket quick as a flash,
A glance at the LOX dial there on the dash.
Moonlight reflecting on earth far below,
Showed nothing amiss in the cold winter's glow.
When what to our wondering eyes should appear,
But a miniature rocket with eight stage of deer.
And manned by a pilot, so lively and quick,
We knew in a moment it must be Saint Nick.
With speed hypersonic, his coursers they came,
He whistled and shouted and called them by name:
"Now Ramo! Now Wooldridge! Now W Dee Dee!
"On Rocketdyne, Convair and ARDC.
"From orbit to orbit to the top of it all,
"Now dash away, dash away, we'll have a ball!"
And then in a twinkle on the scope did appear,
The prancing and pawing of each little deer.
Smooth as a jet stream above a high cloud,
Gathering speed as he nodded and bowed.
He was dressed up for space from his helmet to boot,
With snowflakes adorning his gravity suit.
A bundle of toys he held strapped to his back,
He looked like a Martian adrift from his track.
His visor how frosted, his dimples how merry,
His thrust-reddened cheeks and his nose like a cherry.
With his eyes on the screen of a small radar set,
He was off on the flight plan already pre-set.
Since the course was set up in advance of the flight,
He relaxed with his pipe for the rest of the night.
He had tightened his seat-belt around his fat belly,
But it vibrated some like a bowl full of jelly.
A mighty good spaceman that jolly old elf,
He was better than Schriever—or even myself.
With a little more thrust then applied to the sled,
He dropped off his booster and darted ahead.
A wink of his eye and a wave of his glove,
He aimed for a planet in orbit above.
The flight was prepared in advance on a "brain."
He would find all the stockings without any strain.
To visit all planets in just one night's tour,
He had to be confident, had to be sure.
So he closed a few switches, and turned on the power,
And was out of this world in less than an hour.
But I heard on our set 'ere he soared out of sight,
"HAPPY CHRISTMAS TO ALL AND TO ALL A GOOD FLIGHT."

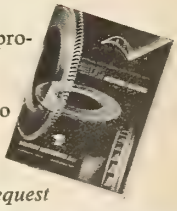
vacuum-cast super-alloy ingots and investment castings



● Maximum strength can be provided in vacuum-melted, vacuum-cast super-alloy investment castings produced by Kolcast from ingot to finished part. Unique Kolcast equipment and exclusive methods keep super-alloy melts and castings free of oxygen and other strength-sapping gases.

Kolcast precision castings of Waspalloy, MT-252, GMR-235, René-41, M-308, and similar melts are poured in inorganic ceramic molds. Contours, dimensions, and surfaces of these castings are so accurate that practically no machining or finishing is required before assembly. High-cost super-alloy scrap is reduced, and expensive, slow machining is practically eliminated.

Even the most complex contours can be accurately cast by the Kolcast vacuum process. Your designs need not be compromised by the production limitations of ordinary casting methods.

Let us send a Kolcast sales engineer to talk with your designers and production men about Kolcast investment parts.

missile miscellany

This page heard the other day a quip that must be old but is nevertheless worth noting: The Pentagon is the only institution run by its own inmates. All of which leads to a question: If the Army has had missile launching vehicles in being and if it's had its own satellites all ready to go, why is it now changing the vehicle and rebuilding the satellites? Seems as though by doing this, they risk a goof—which it can ill afford at the moment.

Meanwhile, this page also hears reports that Army Ballistic Missile Agency may be set up as the Government's nonservice missile research and development center. This means it would be run by the Department of Defense.

Government must have plenty of selection in space flight projects. A quick check reveals that no fewer than 30 U.S. companies have proposals for putting everything from TV cameras to men into outer space. Some even have suggested ways of getting them back!

Speaking of space, preliminary analysis of telemetered Far Side results indicates that gravity, rather than decreasing simply as the square of the distance from the center of the earth, actually "wobbles"—i.e., both decreases and increases with distance. No attempt to explain this has been made, but there seems to be a possibility that the earth's very strong electrical field and the relatively dense "atmosphere" of charged particles up to 40,000 miles may be a factor.

"What we need in Washington are more eggheads and fewer fatheads" . . . Dr. Fred L. Whipple, "The advancement of science in the U.S. is not up to the scienists, but to top Government planners." . . . Trevor Gardner suggests we drop Vanguard and fire more ICBMs . . . Navy Captain Irwin S. Moore, says the next war, if it comes, will cost the U.S. $4,000,000,000,000 (that's four trillion) . . .

NACA is reported to have given up on magnesium and boron slurries with hydrocarbons as high-energy fuels. Meanwhile, Vitro Corp. reports that it has solved problem of boron deposits in zip-fuel systems. Sounds like another round we had, where no fewer than three different companies claimed credit for having solved Jupiter nose cone re-entry problems. Actually Jupiter nose cone is of machined metal coated with Rockyde. Companies participating in its development include Jet Propulsion Laboratory, Cooper Development, Cook Electric, Norton Abrasives. Contrary to reports, Jupiter nose cone is capable of full velocity re-entry—uses Cook parachute recovery system only after it has re-entered. This is a device designed primarily for research and development rather than for incorporation into an operational weapons system.

Meanwhile, the other day this page was asked what it knew about Sargo, "a transitional missile fired from underwater . . ." Also, if it could put any

light on Big Bear, Middle Bear and Little Bear, another missile project series.

From the West Coast, word that Lockheed has been given a contract or letter of intent to go ahead with a moon rocket; also word of a go-ahead on Pied Piper, that same company's proposal for a reconnaissance satellite. And now a suggestion that homing pigeons raised in Moscow be used as guidance systems for ICBMs. And a note of incidental intelligence—slowing of meson decay at high velocities provides proof of Einstein's General Relativity Theory that things slow down when near-light velocities are reached—clocks run slower, etc. Another relativity calculation—a rod going 161,000 miles per second would shrink to half its length in the direction of flight. Good to know for a flight to Alpha Centauri!

PARIS PRESSE correspondent, Albert Ducrocq, after an extensive visit to Russia reports that Reds are using boron and lithium for propulsion already; also that they've discovered how to store monatomic hydrogen and are using it too. And a suggestion from elsewhere that they have done considerable work—successfully—on propellant systems that emphasize effluxes of greater mass, lower velocity . . . and no doubt anywhere that they're doing quite well at the game.

Many methods of manned re-entry are being suggested and developed. AVCO and Cook Electric are working on parachute devices. AVCO thinks in terms of steel (or other high-temperature material) parachutes—admits structure poses problems. Cook claims it can be done with cloth 'chutes in series. Two Russian re-entry proposals are: Continuous dereefing of a cloth parachute—starts out small and gets bigger as velocity is slowed. Other method would use steel 'chute and come in like a falling leaf. It's been calculated that Sputnik II, if it had popped a 'chute system at its perigee, would have returned safely to earth within 24 hours. Another approach to manned re-entry is much more sophisticated—now in the laboratory development stage—involves magnetohydrodynamics. This works on the principle that a strong magnetic field will bulge out the shock wave in the ionized layer ahead of the re-entering body with double results: drag to slow it down; and less heat transfer due to pushing away of hot air at nose. Also, system can generate its own electric power, picking up current from ionized layer with magnetic coils.

Back to Vanguard again: Stewart Committee that selected Vanguard over Orbiter did not do so with a unanimous decision. Three members of the committee voted against Vanguard, including C. C. Furnas and H. J. Stewart. Minority report is point-by-point and is alleged to make very good reading. And a question: Why has the R&D balance been so much this way . . . . . r&D

Amazing new performance in accelerometers

. . . with CEC's exclusive electrokinetic principle

Three self-generating, dynamic accelerometers for the measurement of accelerations from .01 g's to 1000 g's are now available from CEC. The exceptional performance characteristics of these accelerometers are made possible by the electrokinetic principle —forcing a polar liquid through a porous substance to create a potential difference between the surfaces of the substance.

Freedom from spurious resonances permits the accurate measurement of acceleration over a frequency spectrum extending to 80 KC. The low internal impedance, from 100K to 400K, permits operation without a high-impedance cathode follower. Operating over a temperature range from —20°F to +150°F, these accelerometers are undamaged by shocks of 5000 g's, and feature negligible response to transverse accelerations. For complete details, call your nearest CEC field office or write for Bulletins CEC 1600-X4, 1601-X4, and 1602-X4.

Subminiature Type 4-242-2 (shown at left) weighs 20 grams, and features a quick-disconnect cable. The Type 4-242-1 (flange mounting) weighs only 8 grams, including 18" attached cable. The Type 4-240-1 (pictured above) operates from 3 cps to 60 KC.

Soviet Affairs

by Dr. Albert Parry

Long before their spectacular triumph with *Sputnik* II, through the years of their preliminary experiments with sending dogs up in rockets, Soviet astroscientists insisted that they were achieving better results than we did with monkeys, mice and guinea pigs. The Soviets said that they were not only reaching higher altitudes with their animals than we with ours, but that we were drugging our animals while Russian dogs were never under narcotics and were thus observed under far more normal conditions. Therefore, Moscow claimed, Russian experiments with "cosmic dogs" were of much greater benefit to space medicine than those made with our monkeys and mice.

So far, this Red claim has gone largely unanswered by our side. If our experimenters have made any reply to the Soviets on this score, the American answer has not been properly publicized. But it should be.

The outburst of indignation from dog lovers regarding *Sputnik* II's passenger is quite puzzling to Russians. As a people they are not so tender hearted toward animals. America's very first Society for Prevention of Cruelty to Animals owes its founding to precisely this Russian hardhearted attitude to animals. The Society was first chartered by the New York State Legislature in 1866 at the suggestion of Henry Bergh, a U.S. diplomat, on his return from Russia. While serving in St. Petersburg as our secretary of the legation (1862-64), he had been outraged by the sight of Russian cabmen mercilessly flogging their fallen horses to bring them back on their feet from the snow or mud. He had also been incensed by the prevailing indifference of Russian passers-by to this cruelty. On coming home to America, and mindful of Britain's legislation and her Royal Society to prevent such cruelty (1822-24), Bergh started a similar movement here.

•

Academician L. I. Sedov, on his return to Moscow from the astronautical meeting at Barcelona (Oct. 6-12), declared that he was "definitely interested" in the papers by U.S. participants at the meeting on "the possibility of building new ion-rocket engines for interplanetary flights;" on "obtaining and utilizing high temperatures up to 30,000 degrees"; on "the development of heat in rockets and artificial satellites while descending and entering into denser strata of the atmosphere."

Sedov also expressed "indubitable interest" in "reports devoted to oriented artificial satellites and certain other problems of aerodynamics" such as the report on sending plastic balloons up to great heights.

On his return from a visit to the United States, Prof. Anatoly Blagonravov also expressed his interest in American rocket firing from balloons (Operation *Far Side*). These experiments were "worthy of attention" of the Soviets, he said.

The above list can tell us just where the Russians now feel they are either behind us and can learn things from us, or are on a par with us but should be ahead.

•

The latest Soviet humor at our expense includes the quip that Americans piled up mountains of talk and preparations and haven't produced even a *Mouse*.

And why should Americans worry so much about Syria, jests a Moscow humorist, when they had better do something about flights to Sirius.

Sirius, we may add, is also known as Canis Majoris or Dog Star.

Half the Size... Uses ½ the Power

OF THE SMALLEST
CONVENTIONAL VCO
NOW AVAILABLE

Uses subminiature tubes and printed circuitry. 9 telemetering oscillators, operational mixer and self-contained power supply, all packaged within .09 cubic feet. Available on all standard RDB channels . . . with either 7.5% or 15% deviation. Uses Cannon DA-15P plug. Any 9 basic oscillators may be used on 9 different RDB channels. Inputs and outputs individually adjustable. Standard 0-3 v input sensitivity.

Linearity: ±0.5% of band width. Power: 30 milliwatts per oscillator. Stability: Drift less than ±3% of full band width. Vibration: 30 G acceleration up to 500 cps. Shock: Up to 100 G. Input: .5 megohm. Output: Sine wave, 1% distortion. Designed to operate as package unit with mixer. Call or write for complete information.

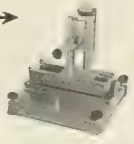
M1238-1818 — *Range 18" x 18", working distance 9" to infinity. Reads to 0.001" up to 24" working distance. Protractor ocular reads to 3 minutes of arc. Image is erect.*

Cut inspection time in half



with new Gaertner Coordinate Cathetometers

These convenient, reliable optical instruments permit making precise coordinate measurements in a vertical plane. The two dimensions are measured with one setting, object does not have to be rotated. Inspection time is cut in half and resetting errors eliminated.

Versatile Gaertner Coordinate Cathetometers are ideally suited for precision measurements on large objects; also objects or points in recessed, remote, or inaccessible locations. Applications include measuring jet engine sections, complicated castings, printed circuits, bolt holes and bosses on large piece parts, traces on cathode ray tubes, etc.

Because these are optical rather than mechanical measuring instruments, you make non-destructive measurements without contact, distortion, or concern about pressure being applied to the object when making a setting. Instruments available in English or Metric system.

M1236-46— Horizontal range 6", vertical range 4". Reads to 0.0001", working distance 5" to infinity.

M1236-22— Range 2" x 2", reads to 0.0001". Working distance 5" to infinity. Shown with 19 mm mounting rod, and without telemicroscope. Instrument permits precise coordinate movement of other objects such as photo cells, probes, etc., in place of telemicroscope.

World Astronautics

by Frederick C. Durant III

Details have just been received on the First Polish Scientific Conference on Rockets and Astronautics held in Warsaw last Spring. Host and organizing body was the Polskie Towarzystwo Astronauticzne. After hearing a tribute by Prof. Dr. E. Olszewski to the 100th anniversary of the birth of Russian rocket pioneer K. E. Tsiolkowski, about 200 "specialists in rocket technology, thermodynamics, aerodynamics, physics and biology and astronomy" settled down to listen to 21 technical papers. Prof. Z. Paczkowski detailed current problems in rocket development and Dr. K. Zarankiewicz (president of the Polish Astronautical Society) outlined the current status of astronautics. All meetings were held at the Warsaw Polytechnic Institute.

Subsequent topics treated in technical papers included ion propulsion (Prof. M. Lunc, L. Bobrowski); nuclear propulsion (O. Wolczek); water-steam rockets (J. Walczewski); turbojet engines (Dr. S. Wojcicki).

Thermodynamics and technology of liquid and solid propellants were covered in papers by M. Zembrzuski, Heger, Bodaniuk and Chrzanowski. Inertial guidance systems were treated by A. Kaczmarczyk. M. Subotowicz presented a concept for achieving propellant economies in a step-rocket system.

Ballistics and guidance systems were discussed by W. Biwan, J. Pie-Kielny, F. Wolnica and Lizon. Rocket jet throttling was treated by Ulam and materials of construction by H. Muster.

On the final day the future was examined and applications of nuclear energy to space flight were considered by S. Wilk. The Polish Society Secretary, W. Geisler, introduced the possibility of using asteroids as earth satellites. An analysis of the case of the planetoid Hermes was treated in particular. Dr. Gadomski presented the results of his calculations on the existence of ecosphere about other stars. His conclusions were that of the 50 stars nearest to the solar system, only 13 could possess an ecosphere which could result in organic life similar to the Earth's. Space medical problems were treated by Dr. Oginski, W. Ciechocinski and Col. Dr. S. Marczewski.

The rocket and astronautical exhibition which had attracted 80,000 people in Silesia (m/r February, pp. 74, 75) was opened in the Warsaw Museum of Technical Science.

In summary, the Polish Astronautical Society gave evidence of deep interest and a sophisticated appreciation of astronautics.

•

In Boston last month re-entry expert Dr. Arthur Kantrowitz, Director of the Avco Research Laboratory announced that Avco had been "studying the problems of manned re-entry for more than a year." He went on to state that "a manned satellite vehicle could be accomplished much more quickly than commonly supposed."

•

For those who still are looking for justification of scientific research in space, we give you the opinion of famed Russian scientist Peter L. Kapitsa:

> ". . . if in any branch of knowledge, possibilities of penetrating a new virgin field of investigation are opening, then it must be done without fail, because the history of science teaches that, as a rule, it is precisely this penetration of new fields that leads to the discovery of those very important phenomena of nature which most significantly widen the paths of development of human culture . . ."

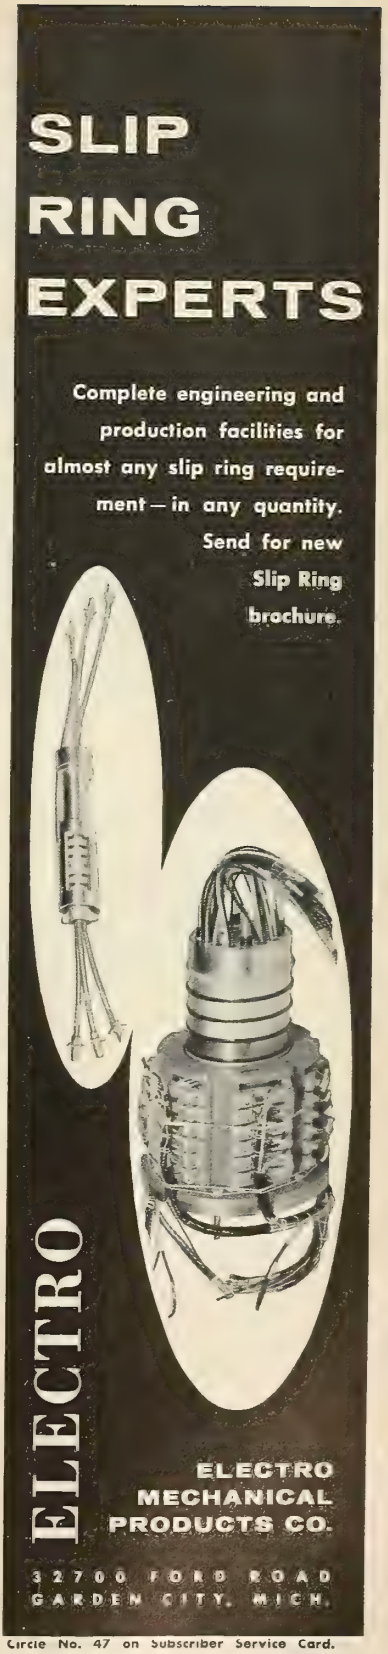
Space Medicine

by Hubertus Strughold, M.D., Ph.D.

U.S. highlight of the International Astronautical Congress in Barcelona, Spain, from 7 to 11 October 1957 was—without question—the report on the recent balloon flight to 102,000 feet by Major David G. Simons. Dr. Simons, Chief of the Space Biology Branch of the Aeromedical Field Laboratory, presented a paper giving his observations during the flight.

Dr. Jan Gadomski, a member of the Polish delegation, delivered a paper on "Star Ecospheres Within a Distance of Seventeen Light Years from the Sun." Dr. Gadomski had screened the numerous stars within this area, and had concluded that only 20 of them could have ecospheres—that is, zones containing planets with conditions favorable to life.

In her paper on "Preparations for Visual Observation of Artificial Earth Satellites," Dr. Alla T. Masevich, an astrophysicist and member of the Soviet Academy of Sciences, who heads about 24 satellite-tracking stations, mentioned that she had some difficulties in persuading an optical factory near Moscow to build special telescopes of the small size needed by her moonwatchers. The factory officials felt that simple binoculars would serve the purpose. After Dr. Masevich and her colleagues gave the factory staff a series of lectures on the meaning and importance of the satellite-tracking project, they not only supplied the telescopes but also established a moonwatch station in their territory.



Prof. Leonard Sedov, leader of the Soviet delegation, made an interesting remark in the course of conversation at the Barcelona meeting. He said: "The important question is not whether a country has a bureaucracy. The question is how much of a bureaucracy the country has."

Dr. Ingeborg Schmidt of the Department of Optometry at the University of Indiana in Bloomington presented a paper at the same meeting on the visibility of satellites in an equatorial orbit. The nucleus of her research was a concept of "areas of potential visibility." The calculations given by Dr. Schmidt for the visibility of equatorial satellites have also turned out to be correct for a satellite of the polar or semipolar type.

In Wiesbaden, Germany, a few days after the Barcelona Congress, Maj. Gen. Harry G. Armstrong, Surgeon of the U.S. Air Force in Europe, arranged a press conference with Maj. Simons and the writer on matters of space medicine. The fact that 60 newspapers from all over Europe sent correspondents to this conference indicated a great deal of popular interest in the subject.

During the week of 27 January 1958, at the meeting of the Institute of the Aeronautical Sciences in New York City, a symposium on "Aeromedical Considerations in Space and Space-Equivalent Flight" will be held. The chairman will be Maj. Gen. Otis O. Benson, Jr., Commandant of the School of Aviation Medicine.

Seven papers will be presented in the symposium. They include "Medical Challenge on the Vertical Frontier," "The Environment of Space in Human Flight," "Supersonic and Hypersonic Flight," "Biodynamics in Human Flight," "Cybernetics in Human Flight," "Future Prospects in Human Flight," and "Interrelation of Space Medicine with Other Fields of Science."

An example of the

Bendix Red Bank

complete line of

high-altitude and missile inverters

As aircraft and missile performance continue to step up, Bendix Red Bank designers continue to lead the field in developing new, high-performance inverters and power packages.

We now offer a complete line of inverters from 6 VA to 5,000 VA, including advanced special-application units and missile type power packages like the one shown above.

If we don't have an inverter to meet your specific needs, we'll design one. For full details, write RED BANK DIVISION, BENDIX AVIATION CORPORATION, EATONTOWN, NEW JERSEY.

missiles and rockets
MAGAZINE OF WORLD ASTRONAUTICS

m/r exclusive:

Education and Industry

An m/r sampling of missile job requirements

EDUCATION means a great deal to your business. If you're in the market for competent, technically trained men, you know the problem. They're hard to come by. And, if you think it's bad now, look ahead: it's going to get worse.

Here are some figures worthy of consideration: The year 1950 shows the highest number of college graduates ever to receive their bachelors' degrees—434,000. By 1955, however, the total had dropped to 287,000, as those delayed by World War II completed their education under the G.I. Bill and the number of students entering college returned to normal.

This story is in three parts. One you've just read. The next is a brief rundown on universities with an interest in the missiles and rockets field. The last part concerns itself with a sampling of missile industry recruiting needs.

What Colleges and Universities are doing in Rockets and Missiles

By the end of the war three universities had established courses in rocketry and related subjects at various levels. These "big 3"—California Institute of Technology, Princeton University and Purdue University—are now being joined by a growing number of schools around the nation.

California Institute of Technology, Pasadena, Calif.: Through its Guggenheim Aeronautical Laboratory (GALCIT) and Jet Propulsion Laboratory, this technology center was the pioneer in fostering the rocket sciences in the U.S. under Theodore von Karman. Present staff consists of Clark B. Milliken, professor of aeronautics (also Chairman of the Board of JPL). E. E. Sechler, A. L. Klein, H. W. Liepmann and H. J. Stewart, all professors of Aeronautics.

Although JPL is administered quite separately from GALCIT, close contact and cooperation are maintained.

University of California at Los Angeles: Recently instituted is a full-scale course in space technology which is being coordinated by H. S. Seifert (Guided Missile Div. of Ramo-Wooldridge Corp.). The course will consist of 2½ hours of lectures each week. Each lecture will be presented in Los Angeles, San Diego and San Francisco, in order to reach the widest possible audience. The lectures will run from Jan. 13, 1958 to May 19, 1958.

All students taking the course must have a technical degree for this first-year graduate-level course.

Following the last lecture, Simon Ramo, H. G. Stever (MIT), Arthur Kantrowitz (AVCO), and R. W. Porter (GE) will form a panel to discuss the progress and problems in the space sciences.

Case Institute of Technology, Cleveland, Ohio: A technical school, Case is interested in the propulsion sciences. H. W. Burlage is director of the Propulsion Laboratory and D. W. Steel heads up the Nuclear Center Project.

Columbia University, New York City: Columbia is interested in materials and has an Institute of Flight Structures, directed by Hans H. Bleich.

Cornell University, Ithaca, N. Y.: The Cornell Aeronautical Laboratory is a nonprofit organization which is wholly owned by the university. Dr. Clifford C. Furnas directed the laboratory operation from its inception in 1946 to 1954, when he became Assistant Secretary of Defense for Research and Development. In 1956, some 1,200 persons were employed here on missile and related projects. The budget is currently at over the $1-million-per-month level.

University of Detroit, Detroit: Currently organizing its Missile and Rocket Section (MARS) to include the research facilities of the 26 other Jesuit schools in the United States. Instructors include: Dr. D. J. Kenney (chemistry) and monopropellant expert Dr. J. A. Hannum (reaction kinetics).

Illinois Institute of Technology, Chicago: Two of the exotic projects at Armour Research Foundation (independent from but associated with Illinois Tech) are stabilization of liquid ozone and boron hydride research. The 24-block Technology Center near south side Chicago has more than 7,500 undergraduate and graduate students in engineering and liberal studies.

Johns Hopkins University, Baltimore: Operates the famous Applied Physics Laboratory at Maryland locations in Silver Spring and nearby Howard County. Organized in 1942, for work on guided missiles, the laboratory has worked on *Terrier* and *Talos* missiles. Of the staff of 1,300, 525 are scientists and engineers.

University of Maryland, College Park, Md.: Sparked by Prof. S. F. Singer, the Physics Department has played a leading role in high-altitude and satellite research. Projects have

included: MOUSE, *Terrapin* and *Far Side*.

Massachusetts Institute of Technology, Cambridge, Mass.: In addition to conventional instruction and training in the pertinent phases of missile technology, MIT also has available a unique student-operated test facility. The MIT Rocket Research Society designs, constructs and tests liquid and solid rockets.

University of Michigan, Ann Arbor, Mich.: Through its Engineering Research Institute (R. G. Folsom, director) and Willow Run Research Center, Michigan has allowed students to participate in such early projects as *Bomarc* and *Wizard*. Its aeronautical center is now located in a new north campus site and under the direction of Professors T. C. Adamson, R. B. Morrison (shock tubes and ramjets) and D. E. Rogers (rockets).

New Mexico College of Agricultural and Mining Arts, State College, N. M.: Fast rising is this missile-minded school, which offers courses related to missiles and rockets in math, physics, and engineering. It operates a program in cooperation with White Sands Proving Grounds. About 250 students are involved. The Physical Science Laboratory has a budget of $2 million for work on satellites, rockets and ECM.

New York University, New York City: This Manhattan school has been particularly active in the propulsion sciences under its chemical engineering department (J. Happel, C. J. Marsel and P. F. Winternitz).

Northwestern University, Evanston, Ill.: Strong point has been fluid mechanics under Prof. Ali Bulent Cambel.

Ohio State University, Columbus, Ohio: Research activities in rockets has included liquid hydrogen rockets and premixed propellants.

Polytechnic Institute of Brooklyn, Brooklyn, N. Y.: Starting in the Fall of 1957, Brooklyn Poly offers a graduate course in rockets and rocketry. Under the directorship of Dr. T. P. Torda, professor of chemical engineering.

Princeton University, Princeton, N. J.: Through its James Forrestal Research Center, Princeton offers the student a chance for graduate research. Operates a rocket test facility. Notable staff members are: Profs. Martin Summerfield and Luigi Crocco, both Robert H. Goddard professors.

Purdue University, West Lafayette, Ind.: In Sept. 1946, Purdue offered its first undergraduate course in jet propulsion. It also offers graduate instruction and research in rockets. Operates a rocket test facility and has done much work in nitric acid systems.

Temple University, Philadelphia: Its Research Institute has been working on high-temperature flame reactions for several years, *viz.*, ozone fluorine.

Wayne State University, Detroit: Dr. G. P. Loweke teaches the course, "Mechanics of Space Flight Orbits."

That, in brief, is what you can expect to find in the way of formalized educational opportunities in missile engineering and associated fields. A few colleges and universities have taken steps to adjust their curricula to the changing times, but it's a spotty effort at best.

Now take a look at the kind of people that industry needs now and you get an idea of the magnitude of the problem 10 years from now. What follows is a sampling of industry's demands for technical help. A survey of every company in the entire industry would reveal even more critical needs.

Lockheed Aircraft Corp.
Missile Systems Division
Sunnyvale, Calif.

Lockheed Aircraft Corp. has positions generally available for engineers and scientists with training and experience, preferably in the missile field, in the following branches: aerodynamics, thermodynamics, guidance and controls, weight systems analysis, antennas & propagation, propulsion, flight dynamics, instrumentation, telemetering, basic loads and structures.

The company has new facilities in the Bay area at Sunnyvale and in Stanford's Industrial Park, Palo Alto, as well as a plant in Van Nuys, Calif. In addition a 4000-acre static test site, located in the Santa Cruz mountains, and flight test bases at the Air Force Missile Development Center, Alamogordo, N. M., and Patrick Air Force Base, Florida.

Flexonics Corp.
1315 South Third Avenue
Maywood, Ill.

Flexonics Corp. was founded in 1902 as the Chicago Tubing and Braiding Co. and at first manufactured only Kantleke gas appliance hose. The company pioneered the development of flexible metal hose in America.

These positions are available or likely to be available at the Research and Development Division, Elgin, Ill., and the Santa Ana Division, Santa Ana, Calif—engineering and product design. Salary open.

Employe relations features include: promotion from within whenever possible; progress reviews twice yearly, paid vacations, retirement (profit-sharing plan), credit union, group insurance, hospitalization, lost time, major medical and dread diseases. Working hours, 40 per week; overtime when authorized.

Raytheon Manufacturing Co.
Waltham 54, Mass.

Raytheon's president, Charles F. Adams, says: "The employment outlook at Raytheon is good. In the fast-moving missile field, our own experience, coupled with national and international events in recent weeks, leads me to believe that there will be a steady expansion of activity in the foreseeable future. This growth calls chiefly for high-caliber, creative engineers in the electronics and aeronautical fields, as well as mathematicians and physicists, and for experts in production engineering who can adapt the electromechanical developments to manufacturing processes.

"Raytheon is seeking electrical engineers, mechanical engineers and physicists for research, development, design and application engineering positions in the fields of guided missiles, electronic equipment (radar, communications, etc.), electron tubes and semiconductor devices. We have a particular need at the present time for engineers with experience in microwave circuitry and/or components. Salaries range up to $12,000. Most of these positions are at the various Raytheon plant locations in Eastern Mass."

Consolidated Electrodynamics Corp.
300 North Sierra Madre Villa
Pasadena, Calif.

Missile expenditures, the electronics industry, according to a recent report, may account for more than $750 million of the $2.5 billion presently allocated for the missile program. In looking ahead, needs will accelerate for development engineers having training and experience in the fields of data reduction, magnetic-tape data processing and transistor circuits. Openings in the categories mentioned will be in the Pasadena, Calif. area. Meanwhile, there is not much in the way of immediate employment opportunities at this time.

Republic Aviation Corp.
Farmingdale,
Long Island, N. Y.

Present openings are for electronics engineers, flight control engineers, engineering laboratory technicians and missile test engineers.

Future openings are in all fields, particularly for engineers with experience in missile guidance, advanced electronic techniques, radar, IR, UHF, SHF, power plants and boosters, nuclear physics, antennas, aerodynamics, thermodynamics, operations research, human engineering, production cost analysis, weights and balance, computer systems, telemetering, structural analysis, servomechanisms and navigation systems. The salary ranges in these fields will be $120 to $250 per week for nonsupervisory positions. All the above positions will be at the Guided Missile Division facilities at Mineola and Hicksville.

Guided Missiles Division has in the past and will continue in the future to make advancements from within whenever possible. All the benefits applicable to the other divisions of Republic Aviation Corp. are available to the employes of this division such as: paid vacation, eight paid holidays per year, liberal pension plan, company-paid medical, surgical and hospitalization insurance.

The Garrett Corp.
9851-9951 Sepulveda Boulevard
Los Angeles 45, Calif.

At present, due largely to unsettled financial conditions in the Department of Defense, it is not likely that this company will be hiring any new engineers at all for some time except in isolated cases of necessity.

Acoustica Associates, Inc.
Shore Road
Glenwood Landing, L. I., N. Y.

This company is an associate contractor in the Atlas ICBM program and has been engaged in development work for the Air Force for almost two years. Positions open for trained personnel range from electronic technicians to project engineers. Positions are available at our main plant in Mineola, L. I., at our testing station in Glenwood Landing, L. I., and our west coast office in Los Angeles. Salaries range from roughly $75 per week for beginning technicians to over $15,000 per year for professional people. All the usual employe benefits such as company paid hospitalization and paid vacations are in effect.

Key employes participate in a stock option plan. Engineers are given every opportunity to expand professionally and to assume greater responsibilities.

Aro, Inc.
Tullahoma, Tenn.

Aro's managing director, R. M. Williams, says: "During the next eight months, Aro, Inc., will probably hire from 15 to 20 recent college graduate engineers for junior staff positions and from 30 to 35 experienced engineers. Our requirements are mainly for those with aeronautical, mechanical and electrical degrees and for physicists. There will be little change in our work force of 2,100 people."

Aro, Inc., is a private corporation, a subsidiary of Sverdrup and Parcel, Inc. of St. Louis, Mo. It was formed in 1950 and is directly concerned with the task of developing new and improved wind-tunnel testing techniques and equipment. There has been a steady, gradual growth from a payroll of less than a hundred to the current 2,100 level. Salaries range from a starting level of about $5,000 to more than $15,000 for top engineering staff assignments.

Advantages of working for Aro, Inc. are as follows: semiannual salary increases, moderate climate and good geographical location, excellent housing, graduate program (resident faculty) providing an opportunity to earn master's degree, relocating expenses, two weeks and two days vacation per year, excellent technical library, assignment to test projects involving advanced and future trends in missiles.

Aerotest Laboratories, Inc.
129-11 18th Ave.
College Point 56, N. Y.

Employment outlook for this company is good. It is expanding its facilities to accommodate the new and additional missile-component testing, which require a new type of employe, one who must be highly imaginative and have a solid analytical and theoretical background.

Advancements are based upon ability, experience and length of service. Salaries are reviewed periodically and raises are given on merit and length of service. Employees receive two weeks vacation yearly. The company provides an insurance program, including medical benefits. A Blue Cross program is in effect. For engineering personnel there are graded overtime payments, unlimited sick leave. For technical personnel, time-and-a-half overtime payments with limited sick leave. Annual bonuses are given to all personnel.

Marquardt Aircraft Co.
16555 Saticoy St.
P. O. Box 2013—South Annex
Van Nuys, Calif.

With respect to technical personnel requirements, Marquardt is interested in quality, rather than quantity of engineers and scientists. The fields of work in which this company is engaged present such a scope and challenge that it requires technical people of superior ability who have the initiative and imagination to push forward into unexplored technological areas. As to numbers of technical people, requirements are based somewhat on the contribution offered by the individual. The man often makes the job and, if the right kind of talent comes along, Marquardt is in a position to create the job to utilize these talents.

All promotions and salary increases are made on a merit basis. Each employe is evaluated twice a year to insure that his contribution is recognized. The benefits plan includes group insurance, retirement, paid vacations and sick leave.

The Electric Storage Battery Co.
12 South 12th St.
Philadelphia 7, Pa.

The Electric Storage Battery Co., Philadelphia, seeks qualified personnel for its expanding missile battery program. Needed are electrical, mechanical and metallurgical engineers and technicians to join its staff of missile and battery experts. Jobs are available at Exide Industrial Division's Philadelphia plant. Engineers and technicians wishing to join in this expanding program may send applications to: Manager of Industrial Relations, The Electric Storage Battery Co., Box 8109, Philadelphia 1, Pa.

The company has a schedule of eight holidays and paid vacations for periods up to four weeks, depending upon length of service. A job evaluation plan and annual salary review assure that no employee is overlooked.

For employes who wish to further their education and enhance their value to the company, a system of tuition refunds is in effect. A patent award system and a suggestion system provide other means of recognition and remuneration.

Convair
A Div. of General Dynamics Corp.
General Office
San Diego 12, Calif.

Employment at Convair-Astronautics is about 6800 at the plant and 1700 at the various test bases. Under present programming for the *Atlas* the level probably will stay at 8500 for some time to come. The division is looking for senior level engineers in such fields as electronics and operations analysis.

Engineers' salaries are reviewed for increases twice yearly. Vacations are two weeks annually (three weeks annually after 12 years). Full group hospitalization insurance that extends to the entire family is available. A retirement plan under which employe contributions are matched by the company is reputedly one of the most generous in the industry. Overtime pay is somewhat restricted.

Narmco Resins and Coating Co.
600 Victoria St.
Coasta Nesa, Calif.

Narmco Resins and Coatings Co. is a member of a group of companies, first founded in 1944 by Dr. G. G. Havens as a research and development organization.

The company is presently devoting considerable time to the research and development of higher-temperature resistant adhesives for missile application. As the demand for missile materials increases, it is natural to assume that the demand for more highly skilled technical people will also increase.

The Narmco philosophy relative to advancement is to develop its own people within the company and grant advancement in accordance with ability and performance. The company is nonunion, rates of pay are equal to or higher than the average rates being paid by similar companies. Narmco grants a two-week paid vacation to all employes after one year; three weeks after ten years employment.

Burroughs Corp.
Defense Contracts Organization
Detroit 32, Mich.

Total employment has increased from 300 in 1954 to nearly 2000 scientists, engineers and technicians today. The Ballistic Missile Division employs more than 200 people. They are engaged in the design, development and prototype construction of the large-scale special purpose computer, which forms the nerve center of the controls in a ballistic missile system.

A Military Field Services Division now numbers more than 1000 people. Its work includes the preparation of detailed technical manuals, specialized training of technical manpower, site planning, preinstallation preparation of equipment, delivery, installation, and listing. These facts indicate the opportunities for scientists, technicians, engineers, and staff people in this area of the business.

Ronan and Kunzl, Inc.
Marshall, Mich.

This is a medium-sized company well established as a leader in the missile field producing cryogenic equipment.

There are no specialists at Ronan & Kunzl, Inc. Well-rounded and fully developed engineers result from this policy.

As ability is shown, advancement is certain.

Starting salaries are based on experience and range from $400 to $700 per month for a 40-hour week. Overtime is paid on a straight time rate. A profit-sharing bonus has been in effect during the past three years. Also offered is an excellent hospitalization and major medical insurance plan, partly paid by the company. Paid vacations are: one week after one year's employment, two weeks after three years and three weeks after ten years.

Chrysler Corp.
Defense Operations Division
P. O. Box 1687
Detroit 31, Mich.

Five years ago, Chrysler Corp. established a Missile Operations Branch in Sterling, Mich., and began working under the direction of the Army Ballistic Missile Agency in the Redstone Ballistic Missile Program. In June 1956, Chrysler was awarded an engineering and production contract on the *Jupiter* intermediate-range ballistic missile. At present, the *Redstone* and *Jupiter* missile systems projects and the ground-handling and launching equipment programs are expanding.

Positions are available in research, fabrication and assembly, and field operations. Expansion in development work has provided new opportunities for electrical, mechanical, power plant, structures and production engineers in design, laboratory and fabrication and assembly activities. Positions are also open for technical writers with electronic specialization, project planning engineers and field service engineers.

North American Aviation Inc.
Missile Development Division
International Airport
Los Angeles 45, Calif.

The Missile Development Division, following the *Navaho* cancellation, has been pretty well shaken down and is trying to project what jobs are available. It has shrunk from about 7100 to approximately 2100 at the present. The ASM is now our major missile project. It's growth potential looks good, but the division only now is entering the development stage.

North American Rocketdyne
6633 Canoga Ave.
Canoga Park, Calif.

This company is in the market for:

Analytical and theoretical engineers with master's degree in physics or mechanical engineering, and substantial theoretical work in mathematics, fluid flow, heat transfer, thermodynamics, servo and control systems, combustion, and elasticity.

Graduate mechanical engineers with substantial course work in vibration, heat transfer, and mathematics.

Research engineers possessing advanced degrees and considerable study of heat transfer, fluid flow, and mathematics.

Engineering specialists with master's degrees in mechanical engineering and study in advanced thermodynamics and/or aerodynamics.

Design and/or research engineers with M.E., E.E., or Ch.E. degrees for electrical, pneumatic, mechanical and electronic control devices.

Research engineers with advanced degrees in physics or mechanical engineering and strong theoretical background in mathematics; experience in analytical development of complex physical phenomena observed in propulsion systems and component development.

Mechanical engineers with strong background in analysis of complex design proposals of advanced concepts of rocket-engine systems.

Research engineer with advanced degree (master's degree and preferably a Ph.D.) in the field of compressible flow, gas dynamics, fluid mechanics, with experience associated with some aspect of internal flow regimes.

Physicists or electronic engineers with Ph.D. degree and strong theoretical mathematics, and electronic background, capable of original thinking.

Ph.D. in mathematics or physics, with a strong background of training in quantum mechanics, classical mechanics, thermodynamics, kinetic theory and electromagnetic theory.

Physicists with Ph.D. degrees and experience in nuclear engineering to study the application of nuclear power for propulsion.

Sperry Gyroscope Co.
Division of Sperry Rand Corp.
Great Neck, N. Y.

Sperry Gyroscope Co. is extensively involved in missile work and pioneered a number of employe relations and employe benefit activities dating back a number of years.

The company will have a decrease in work force of about 300 by the end of the year and an additional 200 to 300 in the early months of 1958, after which, Sperry Gyroscope predicts a building-up again so that they will return to, or above, their present work force of 17,400. Part of this build-up is based upon increased activity in the missile field.

At present, the company is involved in 12 missile projects ranging from complete weapon system responsibility through development and production of subsystems on down to inertial devices, instrumentation and automatic checkout equipment.

Ampex Corp.
Redwood City, Calif.

Ampex Corp. is not a prime contractor in the missile field, but manufactures major components, *e.g.,* magnetic-tape recording systems for telemetry and test. Employment levels are not directly responsive to defense business since the company manufactures magnetic-tape recording equipment for consumer and professional broadcast and television use.

Robert Sackman, vice president and general manager, says: "I feel that after a period of reappraisal at top level in the Administration, probably by the President himself, the missile program will take its place in fact, not just in words, as the Number One defense job of the country. All firms directly and indirectly connected with this industry will feel the impact of increased business in the late winter and early spring as the result of this decision."

Phillips Petroleum Co.
Bartlesville, Okla.

The growth of Phillips Petroleum Co. has been phenomenal—from a $3-million corporation with 27 employes in 1917 to a corporation with assets of more than a billion dollars and more than 27,000 employees. The company's planned expansion and diversity of products should provide for continued, steady growth and a high level of stability.

In 1951, with extensive investigations of rocket fuels from petroleum-based materials already accomplished, Phillips was selected by the U.S. Air Force from more than 30 firms as contractor-operator of Air Force Plant No. 66 near McGregor, Tex., for the development and production of solid fuels for rockets of the "jet-assist-take-off" (JATO) type. This is the only solid-propellant rocket engine employing this kind of fuel which meets all Air Force performance requirements.

Other work under way includes development of large booster rockets, air-to-air missiles and plastic cases for solid-propellant rockets.

The Joclin Manufacturing Co.
Lufbery Ave.,
Wallingford, Conn.

Positions will need to be filled in all departments, particularly in development and sales. Salary ranges and employe benefits are comparable with the most progressive in industry. Particularly important is the growth curve of the company which has tripled in the past two years and promises to continue at this rate for at least the next five years.

Boeing Airplane Co.
Pilotless Aircraft Div.
Seattle, Wash.

This company foresees a continuation of the trend toward increasing the proportion of procurement funds which are spent for missiles as compared to aircraft. Employment in missile work will continue to increase. Boeing expects its Pilotless Aircraft Division to double in size within the next five years. Right now—in line with most of the rest of the industry—Boeing is not hiring any except highly skilled people in specific job areas. This is a situation which probably will change rapidly.

It is company policy to advance a man according to his ability and accomplishments. Boeing has established comprehensive programs for graduate study, scholarship awards, a voluntary training schedule and a management development program.

An invention incentive plan and a suggestion award system are two ways an employe can earn big bonus dollars. If the patent is granted, the employe receives an additional payment plus 20% of any royalties received. Individual awards have gone as high as $11,500.

A large majority of employes subscribe to the Group Life Insurance plan. Boeing offers the best available medical, surgical and hospital coverage to fit the needs of the employe in each area.★

Time grows short for meeting

The Red Education Challenge

by Dr. Albert Parry
Colgate University

TECHNICAL EDUCATION in the Soviet Union starts early and is thorough.

Until 1955, Soviet children spent 30 per cent of the first four years of schooling on science. In the next three to six years they spent 46 per cent of their time on science. Currently, time devoted to science study has been upped to 53 per cent.

In the 10-year Soviet school, from the ages of seven to 17, all students have to take 10 years of mathematics; five years of biology; five years of physics; four years of chemistry; and one year of astronomy.

They begin the study of biology at the age of 10; algebra, geometry and physics at 12; chemistry at 13; trigonometry, calculus and astronomy at 16.

During a typical recent year (1955) less than one-third of our high school graduates had taken a year of chemistry, about one-fourth had had a year of physics, and only one graduate out of 15 had taken advanced mathematics.

Rigors of the College Level

In a number of our high schools, some of the exact sciences are not available even for those boys and girls who may want them.

Although most of our high schools offer a general science course, it is considerably watered down compared with the solid training Russian youngsters get. And at that, only a little more than one-fifth of our American students take that feeble course.

Soviet secondary-school students receive about five times more hours in science and mathematics than the minimum required for entrance by a high-caliber American college.

So good is the technical-scientific preparation of a Soviet student that at the end of his 10-year schooling he knows more than an American science major at the end of 13 years of schooling.

On the college level a Russian student spends 27 per cent of his time in general science and 67 per cent in his field of specialization. The remaining six per cent is devoted to the study of Marxism-Leninism (which, incidentally, used to have a more important part in the curriculum, but has yielded in recent years to science).

Soviet engineering schools require five and one-half years of study compared with the American four-year college program. While our engineering colleges give our student 3700 to 4000 instruction hours in 22 to 25 subjects before graduating him, Soviet engineering schools cram the student with 5200 to 5500 instruction hours in 35 to 40 individual subjects.

As in their middle and lower schools, their college and university classes meet six days a week. The Russian school year on all levels is 10 months long, not eight as in our colleges.

In the Soviet Union foreign languages are taught primarily to enable budding Soviet engineers and scientists to read engineering and scientific literature in those languages.

The study of a foreign language is compulsory in Soviet schools. A student is started at the age of 11. By the time he graduates from a secondary school at the age of 17 he has had six years of either English, German or French. Forty per cent of all primary and secondary-school students and two-thirds of Soviet college students take English.

Only 14 per cent of all our public school students study a foreign language. Only about 10 U.S. high schools or preparatory schools teach Russian and only a handful of the students at these schools take Russian. The situation is not too much better in our colleges and universities—less than 200 of them teach Russian. The classes are small and the dropout rate of such courses is high.

Advanced Training and Research

There are only 33 universities in the Soviet Union, but, unlike ours, these schools do not concentrate on liberal arts. Instead, they emphasize advanced scientific training.

In addition, there are some 800 specialized colleges or "institutes" as the Russians call them. Of this impressive number, 177 are engineering institutes covering every conceivable field and specialty.

A typical engineering college, such as the Novocherkassk Polytechnical Institute in the Don River region, graduates 1100 to 1200 specialists of several kinds annually. The Kalinin Polytechnical Institute in Leningrad alone graduates more than 500 metallurgical engineers each year compared with some 660 metallurgists graduated by all our American colleges together.

Last spring all Soviet colleges graduated a total of 265,000 technical specialists, of whom 80,000 were engineers, or two and one-half times as many as we did. Our total annual engineering graduates number 32,000.

A great deal of Russia's top-level research is done at the Academy of Sciences and its numerous institutes. These have comparatively few students, presumably the best of each year's crop culled from the general run of colleges. But the country's outstanding savants are usually attached to the Academy's institutes where they are given well-equipped laboratories, ample staffs and any other necessary equipment.

Tuition on all levels of Soviet schooling is free, and in addition college students who excel are rewarded with scholarships and fellowships. A college student who gets mostly "A" grades and only a few "B"s is given such a scholarship, but with the very first "C" this monetary aid ceases.

While not sumptuous, such assistance enables the student to finish his courses without working on the side. Very few Soviet students ever take any side jobs. But in the summer they either serve as apprentices in their future professions or help with the crops in Western Siberia and North Kazakhstan as "volunteers."

Straight "A" records bring with them higher scholarships. The more advanced and specialized a student, the more of a stipend he receives from the Soviet state. Similarly, among Soviet professors, the more learned an ex-

pert, the more salary and extras he gets. Full professors in the USSR are paid 16 times the average laborer's wage. In the United States a full professor gets only two and one-half times the average laborer's wage.

The Coin's Reverse Side

The Soviet 10-year schools are not as prevalent as would appear from their propaganda. The Moscow government says that such schools will be universal in the USSR by 1960. Right now seven-year schools are far more general, while 10-year schools are found mainly in cities and in only a few rural areas. Only 15 per cent of all Soviet children complete those 10-year schools.

Graduation from a 10-year school does not guarantee a chance to go to college. Only one out of every 12 applicants to Russia's better engineering schools and the science departments of her universities is accepted. Nor does the Soviet government feel it has enough other college facilities for all those young men and women who want a higher education.

There is now an all-out government campaign in Russia to convince the nation's youth that they can be useful and happy without going to college, that for many of them lifelong careers as mechanics, plain workers or collective milkmaids can also be very satisfying. Much dissatisfaction and restlessness among the USSR's lower-strata youth can now be noted, traceable among other things to this exclusion from higher schooling and better careers.

Only some 30 per cent of those now graduating from Russia's 10-year schools go to colleges and universities. Others, both seven-year and 10-year school graduates (the vast majority of Soviet youth and girls), are directed to secondary technical schools, to manual-training schools (called "labor-reserve" schools) or straight to low-paid factory and farm jobs.

The "Privilegentsia"

Complaints are heard increasingly in the Soviet Union that sons and daughters of important Communists such as political bosses, well-heeled managers and engineers, army marshals and generals and navy admirals get undeserved good grades in schools, that they gain college entrance while gifted children of lower classes and poorer families have to quit school after the seventh or 10th year at age 14 or 17. There are stories of the rich and powerful bribing school directors and examiners. Some such complaints find their way into the Soviet press.

The charge frequently is made by the Russians themselves that much Soviet training in secondary and high schools is theory only, resulting in little practical knowledge, chiefly because both teachers and pupils have new "upper-class" reluctance to dirty their hands on machinery. On one occasion KOMSOMOLSKAYA PRAVDA wrote bitterly: "Some graduates boast of their 'deep' knowledge of physics, yet don't know how to change a burned fuse."

Inefficiency of teachers and laziness of students are another theme of lament. In a letter to the editor of LITERATURNAYA GAZETA, two professors of a teachers' college near Moscow charged that much foreign language study in Soviet schools is nominal only because of this inefficiency and laziness: "Secondary-school students complete their education with very weak knowledge in this field. Also, many specialists graduating from colleges know foreign languages poorly."

Only six out of every 10 Russians who go to college graduate, and of these (the criticism is made), not all deserve their diplomas.

On graduating from college, young Russians are given five days to rest up and pack before they are sent off to jobs which they have to stay with for a minimum of three years. A picked handful from each graduating class are kept at school for advanced postgraduate study as *aspiranty* for a candidate's degree, the equivalent of our master's degree or slightly higher. Eventually a few may become doctors of philosophy.

There is an intermittent wail in the Soviet press that some of these "chosen few" are picked not for their talents or efforts but because of their fathers' pull. Another frequent complaint is that graduates assigned to jobs in the provinces use their families' influence to have the assignments changed. They want to remain in Moscow and other large cities, amid the bright lights and comforts that go with the bureaucratic or technocratic privileges of their parents.

That the Soviets are ahead of us in certain very important phases of rocketry is all too evident now. But this does not mean that, because of their educational system, they are ahead of us in every field of science and engineering. Even the statistics on the number of Soviet specialists, now cited as proof of overall Russian superiority over us, may be misleading.

In our figures of American engineers and technicians graduated annually, we do not usually include the vast numbers of workers and foremen trained on their jobs to handle machinery. But these are the skills for which the Soviet authorities often issue special diplomas or certificates. We do not. Much Soviet training is in schools, not on the job, as is our practice. This makes a difference in the statistics of skilled "graduates."

Our farmers can drive and fix tractors without needing diplomas and are not counted in our rolls of school-trained "specialists." Nor do we give diplomas to those who can mix the right feed or medicine for farm animals. But in Russia, tractor drivers and mechanics are in a definite "skilled" category, and so are "higher-grade" cattle tenders, called zootekhniki.

It is true that in our country not enough effort, time, money and manpower go into basic research. In some fields of research the Soviets handle things differently and better.

However, on his recent return from a visit to Russian laboratories, one of our scientists, Dr. Donald J. Hughes of the Brookhaven National Laboratory in Long Island, reported surprising gaps in Soviet atomic research.

This suggests that while pouring the best of their basic research forces into one field—rocketry—the Russians disregard certain other vital branches of science and technology.

Propaganda Aspects Important

The most crucial deficiency in Soviet education, however, is the fact that it produces narrow experts lacking well-rounded knowledge and understanding of the world around them.

The Kremlin gives its young training that is technical and scientific, a thorough and often excellent education in blueprints and machinery, but instead of liberal arts it feeds them propaganda, in lieu of humanities it tries to imbue them with hatred for humanity.

A young Russian who defected to us once said:

"The Soviets want people to be brilliant in their field, but nonthinking insofar as politics and propaganda are concerned. When they succeed in creating a brilliant man who cannot think, they will have achieved their ideal society."

As we meet the Soviet challenge by changing certain aspects of our mass education, we must take care not to repeat the bad Soviet error of swamping young minds with technology to the exclusion of everything else. Our spirit of broad inquiry and of freedom in quest must be preserved. Such is the other challenge of Soviet education which also must be met if we are to survive as truly free men and women.★

Minuteman to Missileman

by Capt. George T. Cahill, Jr.
U.S. Army Air Defense Command

SINCE THE HISTORIC era of the Minuteman, the increasingly impersonal aspect of warfare has presented a problem in regard to manpower procurement for the Armed Forces. The National Guard and the Reserves have probably more closely approached the hometown defense appeal and purpose as exemplified by the Minuteman. In wartime the National Guard and Reserves fight away from home whenever the tactical situation dictates.

In early 1954, Army antiaircraft artillery guided missile sites began to supplement, and in some instances replace, antiaircraft gun sites around our great metropolitan and strategic defense areas. The number of these sites is increasing monthly. During the past year alone, the number of *Nike* battalions has increased by 51 per cent.

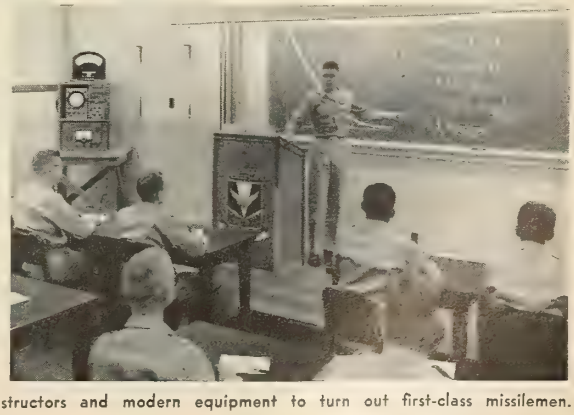
The sites, stretching from coast to coast, are under the direct operational control of the Army Air Defense Command (ARADCOM) with headquarters at Colorado Springs, Colo., and comprise the Army element of a joint headquarters known as the North American Air Defense Command (NORAD). The Army Air Defense Command is led by Lt. Gen. Charles E. Hart, a veteran of more than 33 years artillery experience.

Establishment of missile sites within metropolitan areas has created daily community relations problems on a scale seldom encountered by the armed services. The Army and the Army Air Defense Command use every available medium to create and maintain harmonious community relations and to educate the public to the necessity for antiaircraft guns and guided missiles being situated in their communities.

Early this year, an announcement of tremendous significance to the American public was made by former Secretary of Defense Charles E. Wilson. He divulged that *Nike-Hercules* will be capable of being armed with an atomic warhead. This will enable a single missile to knock down entire fleets of enemy aircraft and certain guided misiles.

It is now a fact that the atomic package will be stored in proximity to communities throughout the country for immediate use. The Department of Defense has explained that accident danger from nuclear air bursts is practically nonexistent. The answer is relatively simple and based on common sense: missile bursts will occur at such high altitudes that no injury will be inflicted on those on the ground.

In some instances, when *Nike* began to appear in public parks and the suburban areas, considerable opposition was expressed by the local citizenry. Fear of the unknown initially alarmed the property owners near *Nike* sites.



But due to the fine spirit of cooperation by the majority of the news media outlets and the admirable work accomplished within the communities by young *Nike* battery commanders, initial opposition has been overcome.

It's difficult to visualize the deadly *Nike* in beautifully landscaped surroundings. Yet, the Army has deliberately encouraged this incongruous setting for the *Nike* by carrying on an extensive and continuing site-beautification program. Local property owners and real estate brokers were reassured when beautification of the sites blended the batteries into the communities in which they are located.

Extensive safety precautions make the *Nike* missile exceptionally safe to handle. Underground storage facilities, and the fact that *Nike* is not capable of detonation until fired, increases the safety margin. Once *Nike* is fired during an actual aerial invasion, any malfunction will automatically detonate the missile in midair. Each site has a standard supply of missiles, and is ready to fire in a matter of seconds. It has been said that a *Nike* site is less dangerous to the community than the local gas station.

Nike is never fired from permanent sites during practice alerts.

Schools like this at Fort Bliss, Texas, use modern facilities, top-notch instructors and modern equipment to turn out first-class missilemen.

Instead, every *Nike* crew in the country attends and competes in practice firing once each year at Red Canyon Range Camp, N.M. Here, the Missilemen maintain proficiency by firing live *Nike* missiles at jet drone planes and by theoretical firing at actual Air Force bombers.

With all the headlines about superweapons, we frequently lose sight of the men who create and use them. Without a driver, an automobile is a useless inanimate object. Man is indispensable and his degree of skill is an intimate correlate to the effectiveness of the weapon.

The days of drafting unskilled and uneducated men into the services is rapidly becoming a matter of history. It ended before the conclusion of the Korean War a scant four years ago. Today's army must be comprised of well-educated, fast, alert thinkers able to act and reason for themselves.

In recognition of the tremendous strides made by industry in wage scales and welfare programs for its employees during the past 20 years, the Department of Defense continues to press Congress for legislation which will increase the attractiveness of a military career. Much favorable legislation has been enacted and still more is pending. However, to date, the severe inconveniences encountered by the soldier are not compensated at a rate commensurate with that of his civilian counterpart.

Frequent assertion is made from within and without the services that the military must compete with industry for skilled manpower; that industry is stealing, outright, technicians trained by the services. To a degree, that is true. However, the situation must be looked at objectively.

Both the services and industry are striving toward the same goal—development of the best possible weapons to be utilized in the defense of this nation. By the same token, the military must not be deprived of the ability to employ these weapons effectively.

Procurement and retention of personnel with potential to absorb the highly technical and specialized training necessary to man complex weapons is a challenge which merits the attention of the top manpower procurement officials of the Army.

As previously emphasized, a weapon, even in this age of hydrogen bombs and electronic brains, is never so self-sufficient that it does not require the direction and guidance of trained electronics specialists. Because of the tremendous outlay of government monies for the procurement of highly developed radar and other electronics equipment, it is imperative that the personnel recruited for assignment to the Army Air Defense Command be of the highest caliber obtainable from the manpower resources of the nation.

The thousands of dollars it costs the taxpayer to train a *Nike* specialist includes work with the latest type equipment and from 38 to 42 weeks of instruction at the Army Antiaircraft Artillery and Guided Missile Center, Fort Bliss, Tex. It adds up to an invaluable technical education.

In the spring of 1956, Charles E. Wilson appointed a committee to study the servicewide problem of skilled personnel retention. This committee, officially designated the Department of Defense Advisory Committee on Professional and Technical Compensation, is referred to as the Cordiner Committee, after its chairman, Ralph J. Cordiner, president of General Electric.

The program proposed by the committee recommends far-reaching legislative and administrative actions for the revision of pay grades to permit additional remuneration for jobs requiring combat leadership and technical, scientific and management ability.

In the meantime, the Army is doing everything possible to create incentives to attract high-caliber youths and, above all, to retain those already in the Army.

Harking back to the day of the Minuteman, who protected his own community, the Army Air Defense Command is striving to develop a recruitment program which is based on the same principle of hometown service.

Photogenic, deadly NIKE-AJAX is examined.

Since its inception in January 1956, through this program alone, more than 12,000 volunteers have entered the Army Air Defense Command for service with missile units. This influx, still in progress, includes many experienced noncommissioned officers bringing into the command leadership qualities vital to the accomplishment of any task, military or civilian. A group of these noncommissioned officers had been serving elsewhere in the Army in career fields.

The results of this type of procurement have proved so gratifying that plans are now under study to permit choice of assignment for nonprior-service personnel.

Young men enlisted under this program will be accepted for a minimum of three years in the Regular Army. This will provide longer retention of trained Missilemen and minimize the present rapid turnover of trained personnel in *Nike* batteries. Each enlistment will save the Government and taxpayers considerable money.

By having men from the local communities serving at *Nike* sites, community relations should be maintained on the highest level attainable. News media and the public as a whole should have a more comprehensive idea of the purpose, mission and problems confronting the *Nike* units in their communities.

The Army Air Defense Command is ready for the sound of the bell signifying the opening round of hostilities, a bell it devoutly hopes will never ring. Her highly trained *Nike* crews, proudly wearing the red shield-shaped *Nike-Ajax* patch, stand alert 24 hours of every day to unleash their destruction against the foe should this become necessary.

ARADCOM, with its *Nike* and other surface-to-air weapons teamed with its sister air defense forces—the sleek jet interceptors of the Air Force, Navy and Marines, the Navy radar picket ships, the Ground Observer Corps and the National Guard—serves grim warning to potential aggressors bent on the invasion by air of the United States.

The Marquis of Queensberry rules will go out the window at the start of the fray. To achieve the knockout, anything goes. Man of the day will be the modern Minuteman—the Missileman. ★

US-USSR Educational Systems—a Comparison

by William P. Lear

Chairman of the Board, Lear, Inc.

MOST PEOPLE are prone to look down on and underestimate the intelligence of persons whose political faith is at variance with their own. Due to this attitude we get a fairly good idea of how the average American is likely to regard the technical and scientific progress of research in the Soviet Union.

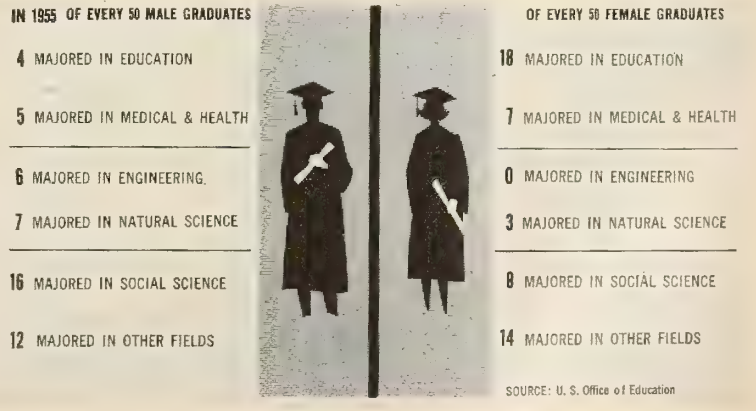
Again, most people in this country are apt to look on our plethora of modern conveniences, such as automatic electrical appliances, radio and television, automobiles, etc., as indicative of scientific progress. They feel this is an indication of our ability to cope better than anybody else with the problems of modern science, including the building of satellites and space ships. We are apt to regard our cherished system of "higher" education for everybody as the correct climate for achieving a dominant position in science and technology.

We cannot evaluate the scientific standing of Soviet Russia against a background of political prejudice and mass-produced comfort. Rather, it behooves us to appraise objectively the Soviet scientific progress during the last several years.

Nothing significant transpired in the USSR during the first decade after the revolution (1919-1927). The condition of the sciences in Russia was very bad since industry was nonexistent. Therefore, they decided to direct their first effort toward science and to make it self-supporting.

About 1927 many Russian scientists working as a gigantic team initiated a project of study which by 1939 had developed into a new science—nonlinear mechanics.

What was surprising, on closer scrutiny of this stupendous work, was the extraordinary harmonious cooperation between the different specialties—pure mathematicians developed new methods which were inspired from engineering developments, while physicists and engineers were dealing freely in the most abstract branches of mathematics, etc.



It is unbelievable that such a gigantic project (four institutes in Moscow, Leningrad, Kiev and Gorky working jointly) was started without any definite objectives. It created a new science which ultimately opened entirely new horizons in almost every direction—electricity, mechanics, electronics, astronomy, biology and econometrics.

How much is there that we do not know about Russian development? Perhaps here is the real reason for occasional surprises, such as when we hear about developments in guided missiles, artificial satellites, etc.

In our democracies, developments like these are likely only in wartime, but in the USSR such organizations work continuously. It is no wonder that scientific developments are reported from the USSR far ahead of our estimated schedule.

This error in judgment very likely arises from the fact that we measure things in terms of the industrial development in the United States. In this respect we are far ahead of the USSR. But this yardstick is hardly applicable inasmuch as in new discoveries the scientific accomplishments are far more important than developments in industry. Also, a highly synchronized and well-coordinated work of a number of well-equipped laboratories, through war and peace, can produce spectacular results simply because the question of money does not come up in a country in which the standard of living is so low. The lack of industry (on the U.S. scale) may be a very adverse factor when mass production is required.

At present there are 306 journals published by perhaps 30 to 40 various

institutes under the supreme direction of the USSR Academy of Sciences. The Academy is unique in that it directs the whole scientific activity of the country —from H bombs, transcontinental missiles, and satellites to growing tomatoes above the Arctic Circle, breeding of animals, etc.

One gets the impression that the number of scientists in the USSR is far greater than here, a fact which has been discussed many times in recent years. In Russia the children are followed up very closely and vocational selection operates very efficiently. If a child shows interest, say, in mathematics, he is pushed systematically in this direction and if he shows good results all expenses are paid by the State. If one takes into account that there is no other outlet than the Government service, it is no wonder that there are so many young scientists of the very first order.

Whether the system is good or bad politically is another story, but as far as the supply of good scientists is concerned, the system of "vocational guidance" and subsequent free training seems to work well, judging from the results achieved during the last three decades.

The present technical superiority of the Soviets is, in my opinion, not accidental, but was bound to happen as a consequence of their superior system of higher technical education.

To enter institutions of higher learning in Russia, as well as in most of the European countries, the individual has to pass very stiff tests to prove that he is entitled to professional treatment. Obviously, such a system weeds out the mediocre ones, before they have a chance to crowd into the universities and drag down the quality of teaching to a level commensurate with their own limited intellect. By setting these rigid standards for the right to pursue higher education, the Soviet has built up a body of engineers and scientists, capable of outstanding achievements.

Slowly and inexorably the Russian system of higher education has overcome the tremendous handicaps imposed on it by the revolution and has now caught up with us, if not surpassed us, in the military sciences.

As a corollary, let us now take a look at the American educational system, and see how it compares with the Russian.

First of all, let us consider our high school education. To attend high school seems to have become the inalienable right of every American youth, regardless of whether or not he has the will and the mental powers to absorb higher learning. As a result, the curricula of the high schools are, with a few exceptions, adjusted to be commensurate with the average level of student intelligence and, perhaps, in order not to impose too much restraint on their extracurricular activities.

Mediocrity and mental impotency are nursed along to the detriment and depreciation of an intelligent minority that should, and will some day, be the leaders in their chosen fields. Therefore, your embryonic scientist enters the university with about two years deficiency in basic education, as compared to the Russian high school student.

He now also faces the task of learning to think independently, which had not been part of his high school curriculum, probably because of the inconvenience this would have imposed on the minds of the greater number of students. Many of his instructors are uninspiring, and have not much more to offer than the text book they are following.

There are, of course, many exceptions in this respect, but, as a rule, the quality and depth of learning among our college and university teachers is greatly below the standards of their European counterparts. *Low salaries* and the *general lack of esteem* in which college professors are generally held in this country are undoubtedly contributing factors in this respect.

And, as in the high school, we find also in the college the tendency, although not to the same extent, to adjust the level and pace of the instruction to suit the slow march of the average intellect.

This state of affairs is literally suicidal in an era in which the survival of a nation depends on its intellectual forces, rather than on its armed might.

If we pursue the present system of higher education, the consequences will, ultimately, be disastrous for this nation.

Some expert opinion holds that the United States ran the risk of losing the last war (World War II), because of a general lack of competency in the fundamental sciences. The production of weapons rather than the superiority of weapons gave us the victory. We won that war, not because of our scientific level, but in spite of it.

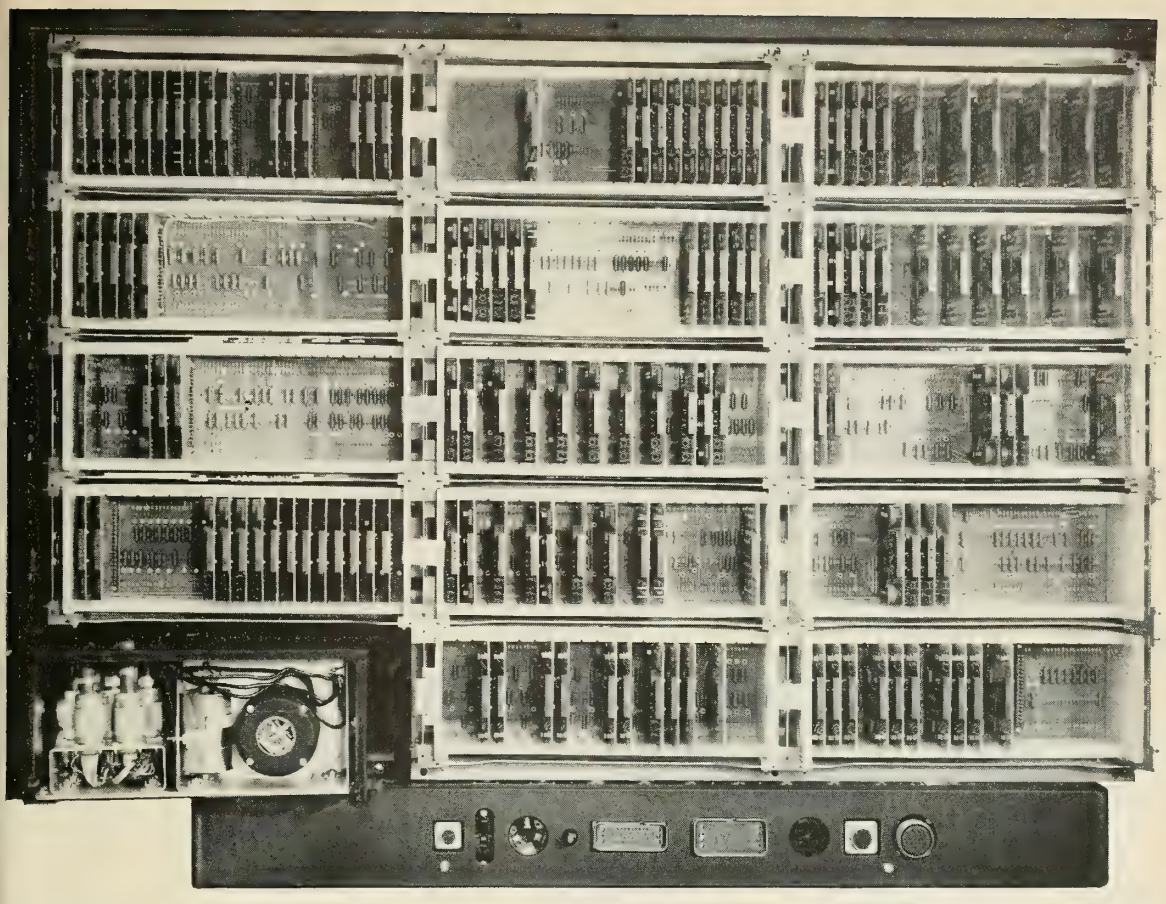
Our development of the atomic bomb was an outstanding technological achievement, but without the European educated scientists, such as Einstein, Bohr, Von Neumann, Fermi and Gamow, just to mention a few, the result would probably have been fizzle instead of fission.

We cannot hope to maintain a comparable level of scientific achievement as long as we persist in using the same mold to shape the mind of the future scientists as that of the future clerk, salesman, storekeeper, and what not.

It should be obvious to intelligent and right-thinking Americans that we must revamp our system of higher education to seek out and give special training to those who offer the best chance to insure our supremacy in scientific thought and development.

First, we must reorganize our high school system so as to separate the boys from the men. At the end of an eight-year elementary school, common to everybody, a separation must be effected on the basis of aptitude and intelligence tests.

Those who pass certain minimum requirements should then, provided they wish to do so, be transferred to what we may call preparatory school, while those who don't pass the tests, or don't wish to go in for higher education, would be transferred to a high school of very much the same make-up as at present. The present four-year course should be compressed into a three-year course and more emphasis be laid on vocational training.



The curriculum of the preparatory school may conveniently be split along two major lines which we may term the modern line and the classical line.

In the modern line, designed to accommodate those who intend to pursue studies in the natural sciences and engineering, the emphasis should be on mathematics, physics, chemistry, German and Russian. The classical line should be designed to further the interests of those who wish to become physicians, lawyers, teachers, etc., with the emphasis on such subjects as philosophy, literature, history, English, French and, perhaps, Latin. The teachers in these preparatory schools should all have advanced college degrees, be adequately compensated, and have a genuine interest in education and the dissemination of knowledge.

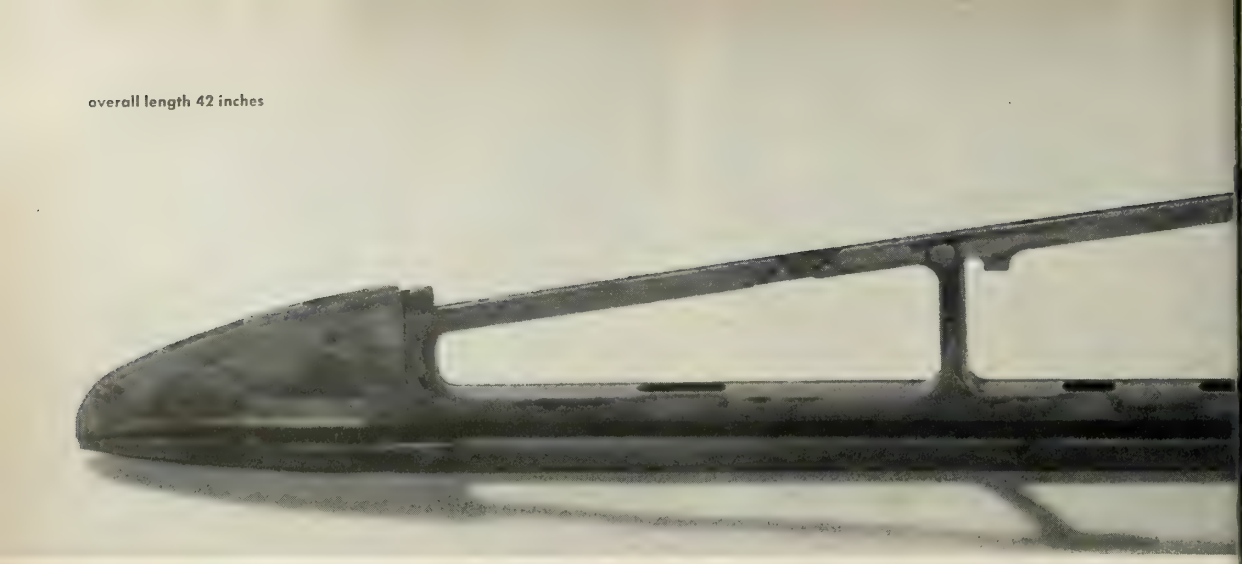
Next, we will have to raise the standards of teaching in our universities in order to exploit to the fullest the much higher intelligence and basic knowledge of those coming from the preparatory school. In cases where the cost of university study is beyond the means of the student, and provided his scholastic record warrants it, the Government should advance the necessary funds in the interest of the nation.

Most people will say that these changes in our higher education are extreme but so are the times in which we live.

We must acknowledge that unless we first lay a broad foundation for scientific development, the resulting structure will be limited in height. One cannot build a skyscraper on the foundation for a one-story house.★

The Role of
PRODUCT ENGINEERING
in Systems Work

It has become characteristic of modern weapons systems that they are required to operate under severe environmental conditions, as well as to meet stringent weight and space limitations. Moreover, the complexity of many of these systems poses additional difficult reliability problems, while at the same time the increasingly critical consequences that depend on the proper functioning of the typical system logically call for a *higher* degree of reliability than previously achieved. The same is true of certain electronic systems for industrial applications, such as the Ramo-Wooldridge digital control computer, some of whose design features are shown above.



Meeting all of these requirements is in large part the responsibility of product engineering. Generally speaking, product engineering starts with a system or subsystem at the breadboard stage and transforms it into the final product, which in addition to meeting all of the requirements previously stated, must be practical to manufacture and to maintain. Such creative productizing requires the development of ingenious mechanical design features, a thorough knowledge of circuit design and component reliability, and a broad familiarity with materials and manufacturing processes.

At Ramo-Wooldridge, the product engineer is an essential member of the research and development team which has the full responsibility for creating new systems, from the initial theoretical studies on into the manufacturing stage. Engineers experienced in product engineering are invited to explore the variety of openings which exist at Ramo-Wooldridge in such fields as airborne electronic and control systems, communications and navigation systems, digital computers and control systems, and electronic instrumentation and test equipment.

FROM 9″ TO 20″

STIFFENED SECTIONS

FROM 10″ TO 24″ O. D.

TUBING

DOW'S NEW EXTRUSION PRESS PACKS 13,200-TON PUNCH

Here's a whole new range of large magnesium extrusions:
24-inch O. D. Tubing 28-inch I-Beams 80-foot-long sections

This mammoth press, newest addition to The Dow Chemical Company's rolling and extrusion mill at Madison, Illinois, is the world's largest magnesium extrusion facility. Its vastly increased capacities afford new opportunities for designers working with light metals. A wide variety of new magnesium applications for aircraft, missile, military and general industrial use are now possible and practical. In addition to extruding magnesium, the press is also available for large aluminum extrusions.

Here's how the big press will increase maximum dimensions of representative magnesium extrusions: Integrally stiffened sections, from 9 to 20 inches wide; I-Beams from 11 to 28 inches high; round tubing from 10 to 24 inches outside diameter; and maximum lengths of 80 feet. A large number of shapes and forms can be produced, limited only by the design of the die through which the metal is extruded. Many complex shapes that formerly required separate operations can now be formed in one operation.

If your design calls for large magnesium or aluminum extrusions, contact the nearest Dow Sales Office or write to THE DOW CHEMICAL COMPANY, Midland, Michigan, Department MA 1406G-1.

Propulsion Engineering

by Alfred J. Zaehringer

FREE RADICAL WORK is underway at Catholic University. Hydrazoic acid has been thermally decomposed to give the NH radical or its polymer, which is a stable, blue paramagnetic solid at liquid nitrogen temperatures. No success has yet been reported in finding a solvent for the free radical, which is among the most stable yet known. Most other free radicals are unstable even at temperatures near absolute zero. Scientists at the Washington, D.C., university have also prepared the dimethylamino radical which reacts to form tetramethyl hydrazine.

FLUORINE COMPOUNDS AVAILABLE for propellant investigators are elemental fluorine, halogen fluorides, nitrogen trifluoride, oxygen difluoride and perchloryl fluoride.

BORON REACTIONS: Iowa State University chemists have decomposed diborane in an inert atmosphere under silent discharge to yield 40% B_4H_{10}, 20% B_5H_9, 30% B_5H_{11}, small amounts of B_6H_{10} and an unknown hydride with nine boron atoms per molecule. The work was sponsored by Callery Chemical. Burning rate of boron metal rods was reported by Experiment, Inc. At 15 psi, the rate is about 2 cm/min and the burning surface temperature was estimated at 2040°C. Rensselaer Polytechnic and Eastman Kodak have teamed up to study the explosive oxidation of pentaborane. Surfaces coated with oxidation products act as catalysts and broaden the explosive-limit range. Carbon monoxide and iron carbonyl inhibit the reaction.

BLOWOUT VELOCITY FOR BORON HYDRIDES IS HIGH. Under same conditions of combustion, NACA illustrates that ethylene combustion with flameholder will blowout at about 47 ft/sec while diborane will go well over 100 ft/sec, without flameout. This means ramjets using boron fuels could cruise at much higher altitudes than with conventional hydrocarbon fuels.

PLENTY OF LITHIUM. Foote Mineral Co. estimates the concentration of lithium in the earth's crust at $4x10^{-3}$%, or about as abundant as lead or six times as plentiful as tin. The company calculates that the reaction of lithium and fluorine could give an I_{sp} of 336 sec and 318 for lithium and oxygen. Lithium hydride is also suggested as a superfuel. Lithium perchlorate also figures high since, on a volume basis, there is 29% more oxygen in $LiClO_4$ at room temperature than in liquid oxygen at the boiling point. It looks like Foote Mineral will team up with Hooker Electrochemical (Niagara Falls, N.Y.) to produce lithium perchlorate by a *direct* electrolytic method. Cost could come way down. This might make it competitive with ammonium perchlorate. Hooker is looking over a site at Montague, Mich., for the plant.

LONG-BURNING SOLID-PROPELLANT MOTORS are in the works. Jet Propulsion Laboratory is working on a water-cooled nozzle for a large solid-propellant rocket motor.

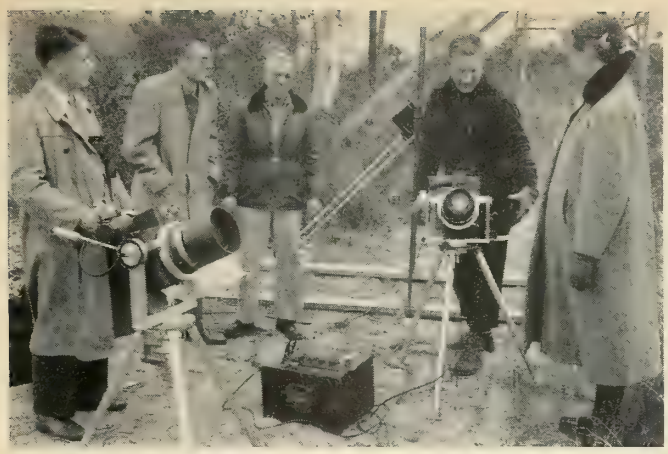
EXISTING SOLIDS WILL BE BOOSTED by three new developments. One firm has built and flown a solid motor that is 97% propellant. Hopes to hit 98% in another six months. Studies going on indicate that burning rates can be jacked up by a factor of 10 without pressure increase. On the other hand, there is one proposal out for operation of combustion pressures of 250,000 psi!

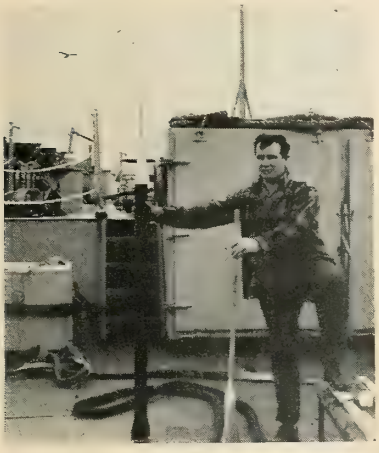
TETRANITROMETHANE IS BACK. Small-scale pilot plant manufacture is underway again. Oxidant or monopropellants would be the logical application

LOX FOR REDSTONE: Army has shown its 4-trailer, mobile, 20 tons/day LOX plant. The low-pressure unit (100 psi) was built by Air Products, Inc. and cost is $1 million. The product is 99.5% pure and the plant can operate at temperatures of −25° to 125°F. It takes one pound of diesel fuel to grind out two pounds of LOX. The four units are for intake, compression, heat exchange and separation.

ORIOLE . . .

a really low-cost research missile





Men learn by doing, and by learning they produce for the good of all men. On this page you see the various steps involved in the assembly for launching of the ORIOLE, a recently proved high-altitude research rocket developed by the University of Maryland and costing less than $300 per copy—except for the booster, a surplus LOKI, which is free. This sting can carry scientific payload to an altitude of 80 or 120 miles, depending solely on its diameter. It has no motor of its own but relies only on its LOKI booster. The ORIOLE sting completely lacks either fins or flare, thus reducing drag to a minimum. It achieves aerodynamic stability because its center of gravity is placed very far forward. The sting lets go from the booster immediately after it has completed its 0.8-second burning time.

Actual designer of the ORIOLE is Richard Bettinger, shown on these pages in the plaid shirt. A graduate student at Maryland, he works under the direction of Astrophysicist Dr. S. Fred Singer (in sports cap). These pictures were taken off Cape Charles, Va., aboard the U.S.S. Launcher where the ORIOLE was successfully tested. Shot to the left shows one of two mosquito-infested ground stations. ORIOLE is fired in a conventional TERRAPIN launcher—shown in the shots right below. Development of the ORIOLE solves one major problem facing U.S. universities—the availability of a simple, low-cast research rocket. Next, a series of readily available launching sites is needed so that students can launch their rockets more or less at will. If it were not for the full cooperation of Navy, Army and Air Force, ORIOLE would still be waiting for its first test.

High-energy George P. Sutton

Backstage with the New ARS President, Booster of Scientific Education

by Erica Cromley

IF THE NEW American Rocket Society president has his way, America will move quickly to close the gap on Russia's impressive output of scientists and engineers.

George P. Sutton, 37, who takes over the ARS reins this month, feels strongly that the government should set up a committee to recommend steps which would: (1) attract more students into scientific and engineering training, (2) expand the number of courses available, (3) raise the quality of available courses, (4) encourage graduates to continue postgraduate studies and (5) raise the level and number of competent instructors.

"It is extremely important that we roll up our sleeves and tackle the problem at the foundation—the schools," he says.

A key scientist in Rocketdyne's early design of the nation's first high-thrust, large rocket engines, Sutton has made prolific contributions to technical education. His book, ROCKET PROPULSION ELEMENTS, standard text in many technical colleges, has been termed *The Book* for rocketry training by many of the country's top missile experts. The Russians were impressed with it too, published a USSR edition, and sent Sutton a free copy.

Throughout the 15 years of his brilliant career Sutton has taken time out to write many technical magazine articles. In 1951 he received the G. Edward Pendray award of the ARS for his outstanding contributions to the literature of jet propulsion.

The current chief of preliminary design for Rocketdyne fell into the rocket business "somewhat by accident," after scuttling a boyhood dream of becoming a doctor.

It happened during a job interview at Aerojet. He was told only that the "highly classified" work involved thermodynamics and hydraulics. Sutton figured he'd be working on hydraulic and heating equipment for aircraft. He accepted and inadvertently began a career in rocketry which has brought him worldwide recognition.

He did have one brief and unexpected fling at his first love—medicine—when he assisted an impatient stork. While working his way through Cal Tech as maintenance engineer at a city hospital, a hurried call for help brought him racing across the street to the hospital's parking lot, which is as close as a new mother got to the delivery room. He used a laboratory clamp ("nonsterilized," says Sutton) to bind the squalling newcomer's umbilical cord and wrapped him in his lab jacket ("also nonsterilized").

As in doctors' families, the Suttons are reconciled to periodic fatherless homelife. Sometimes Mrs. Yvonne Sutton wonders whether she wouldn't see more of him if he had gone into medicine. He is frequently called on

Left—George assists daughters Marilyn (left) and Christine in the study of astronomy. Right—George, Marilyn and Yvonne study the sky.

to lecture and is away from home on about 10 week-long trips each year.

Because he now travels so much, the Suttons are not as active in community affairs as they had been, preferring to spend as much time as possible in family activities. They are, however, active in the Woodland Hills, Calif. community band to which daughter Marilyn, 10, contributes her clarinet-playing talents. There's a band at home, too. Mrs. Sutton plays the marimba, Pa Sutton is the accordianist, Christine, 12, is pianist while Marilyn tootles.

"It took us a year and a half before we could play together so it sounded like anything," Mrs. Sutton laughs. "But we're real 'cool' now." Lately, Henshaw Street, Woodland Hills has been jumping to the strains of "True Love" and "Tammy", favorite numbers of the Sutton Swing Quartet.

Life with this scientist is seldom dull. Mrs. S. recalls a recent evening when they came home from a party, at one a.m., grabbed the telescope and went out on the lawn to check the positions of the stars. Then they set the alarm for four a.m., and with bathrobes flying, rechecked them. Before they settled back to bed for good Mrs. S. recounts, "George looked up his astronomy book to make sure the stars were where they were supposed to be. He was very pleased to find they were."

The Sutton family agree on one family project each year. This year it's Operation "Skywatch" with a German telescope bought during the rocket experts recent International Astronautics Federation meeting in Barcelona. Last year, it was Operation "Mountain Climbing." The Suttons are skiers and plan one ski vacation each year without the children.

High-energy George P. Sutton

Mrs. S. describes her spouse as "clear-thinking, concise and able to sum up any issue quickly to a sound conclusion." He has two pet peeves: lack of organization and weeding the garden.

"He's easy to work with and a bug on waltzes," says Rocketdyne's Assistant Chief Engineer Paul Vogt. "Once he jarred the car pool by waltzing the car down an empty street in time to a Strauss waltz coming in over the radio."

In his "spare time" Sutton keeps abreast of things by reading avidly: m/r, *Business Week, Time, Reader's Digest* and ARS publications.

Sutton began his career in rocketry in 1943, after graduation from California Institute of Technology with a Master of Science degree in mechanical engineering. His earlier studies included an Associate of Arts degree in mechanical engineering from Cal Tech in 1942. Today he continues advanced studies in several fields.

Sutton joined a nucleus group of North American Aviation guided missile scientists in 1946 as a research engineer. He subsequently has held successive prominent roles in that group's development of high-thrust rocket propulsion systems and has been the chief of Rocketdyne's preliminary design section since 1953.

He has served on the faculties for Mechanical Engineering at the California Institute of Technology, the University of Southern California and the University of California at Los Angeles.

Among his current contributions to science is his active participation on the Nomenclature Subcommittee of the American Standards Association. The group has developed the first nationally accepted standard symbols and terms for rocket propulsion.

Sutton is a founder and the first president of the Southern California Section of the American Rocket Society and currently is a national director of the society. He has served three years as a director of the society, as Chairman of its National Membership Committee, and Awards Committee. He is the 1957 Vice President and has been nominated for ARS president in 1958. He also is a member of the American Society of Mechanical Engineers, the Institute of Aeronautical Sciences, the British Interplanetary Society and Deutsche Gesellschaft für Raketentechnik und Raumfahrt (the German Rocket Society).★

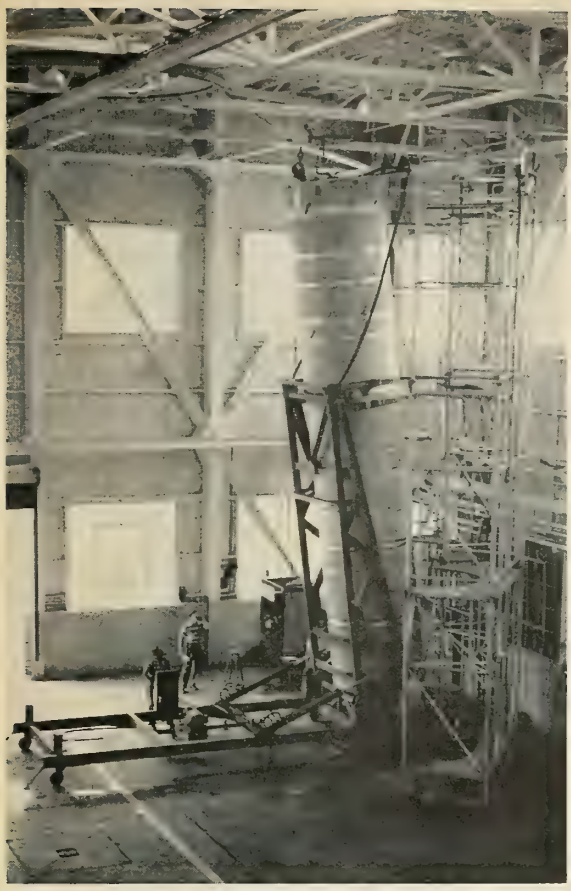
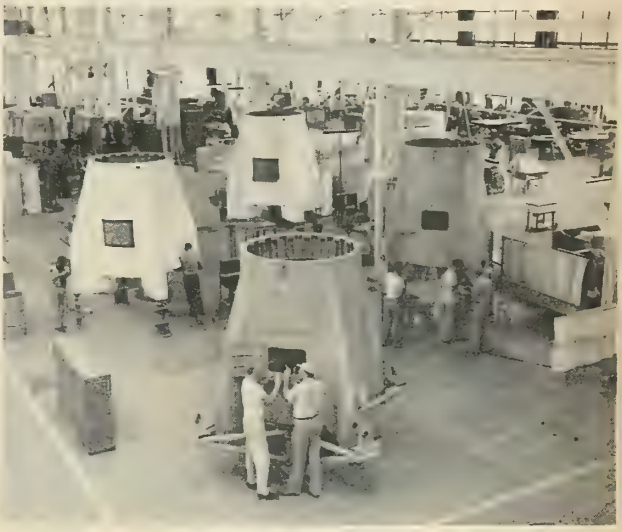
Fabricating the REDSTONE

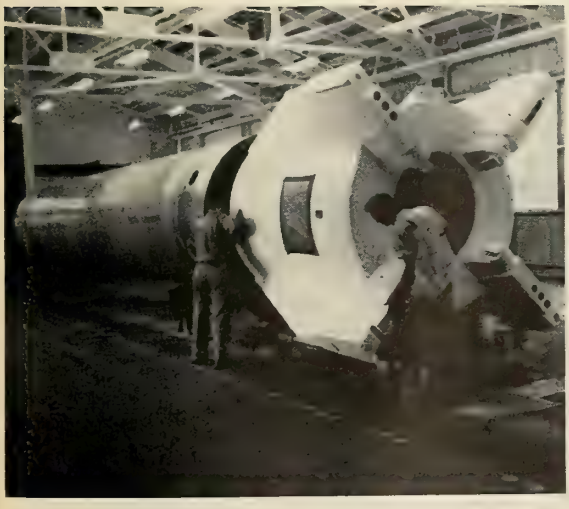
Reynolds Metals Co. has been fabricating and assembling REDSTONE missile fuselages at its Sheffield, Ala. plant since 1952. The plant fabricates the nose, fuel body, rocket-engine housing and tail fins, and assembles the complete fuselage. Engines, guidance systems and controls are installed elsewhere by Rocketdyne, Ford Instrument Co., Chrysler and ABMA. Left—A horizontal mill cuts sections of the missile fuselage to length.

The JUPITER IRBM is also being fabricated and assembled at the Sheffield plant. Sheet material for the REDSTONE is from McCook and Listerhill, tubing from Phoenix, stampings from Louisville Plant 12. The advanced nature of the program demands a high degree of skill from the engineers and production men. Currently, more than 200 people are employed at the plant. Left—Body sections are welded together on automatic welding machine.



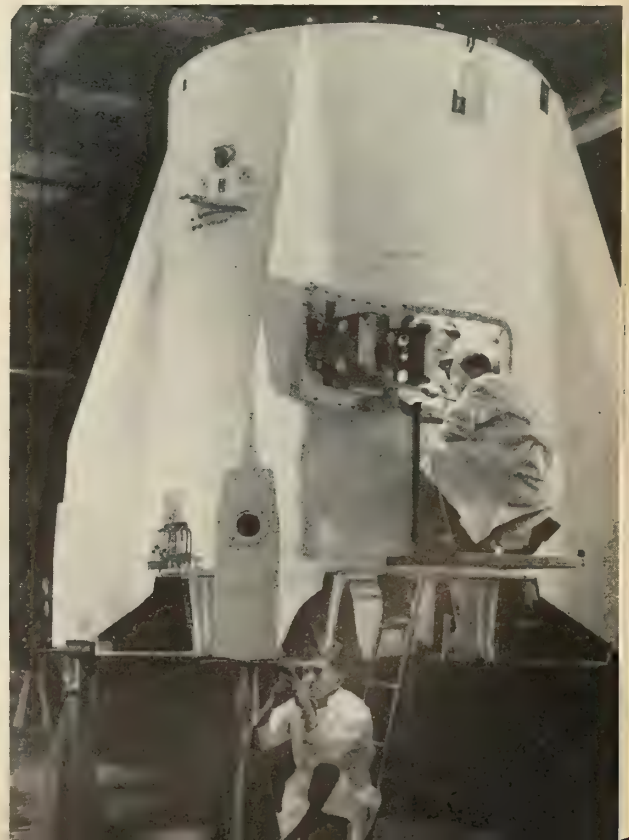


Exacting quality control techniques are employed throughout the entire fabricating operation. All welds are X-rayed and each component is protected constantly from dirt or damage. Above—Through a port opening at the aft end of one of the missiles, two employees are shown inside the fuel tank installing fuel and wire conduits. Left—View of welding machine in operation. After the joint has been completely welded a radiographer inspects the bead.



missile production

The REDSTONE is assembled into three major component parts, one consisting of the rocket engine and fin section, one, the tank section and the other, the control-system and warhead section. Control and warhead section is approximately 29 ft. in length, the tank section 24 ft. and the engine housing 10 ft. Left —A tank section of the body is raised into position for a hydrostatic test. Water, under pressure, is used to check for leaks.



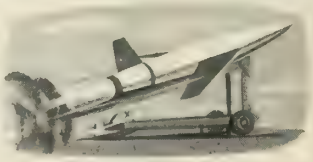
The ruggedness of the REDSTONE is apparent in these photos of the rocket-engine housing and fins. It is controlled in flight by graphite vanes attached to the fins and protruding into the exhaust stream of the rocket. Above—Tail sections of the missile in various stages of assembly at the Reynolds Sheffield plant.

The REDSTONE is rapidly becoming the workhorse of the infant space age. Its role as the first stage for the three-stage JUPITER-C research rocket and the recent decision to put the JUPITER-C into the satellite service have made the REDSTONE's task extremely vital. Above—Reynolds workmen wheel a tail section into place behind the center section. Right—Chrysler workers install mechanisms in missile tail section after delivery by Reynolds.

GREER designs and builds the most efficient and dependable HYDRAULIC SYSTEMS for your missile launcher!

GREER PROVIDES A COMPLETE POWER PACKAGE AT LOW COST!

Greer's enviable reputation for the creation of hydraulic systems began more than 15 years ago. Greer has designed, developed and built hundreds of hydraulic systems for leading aircraft and equipment manufacturers. You'll find Greer systems on planes, ships, missiles, submarines, buses, machinery—and on almost any hydraulic equipment you can name.



Greer's important contribution in the guided missile field includes major work on the Bomarc, Redstone, Talos, Terrier and Thor. Greer has provided systems and components for these operational and experimental missiles since the inception of the program.

Greer's staff of engineers is ready to put this hard-to-find experience and know-how to work for you. Greer now offers you on-time delivery of a complete hydraulic system for your missile launcher... probably at what it would cost you to design the system alone. Contact us now for immediate action.

Missile Age Machining

by A. B. Albrecht
Monarch Machine Tool Co.

BECAUSE so sizeable a portion of our production efforts is not devoted to the machining of missile, rocket and jet components, rapid engineering advances in materials and designs have challenged manufacturers to produce precision parts on short notice for use in development models. In addition, these manufacturers have had to supply reliable and interchangeable parts for rocket powerplants and missiles already in service.

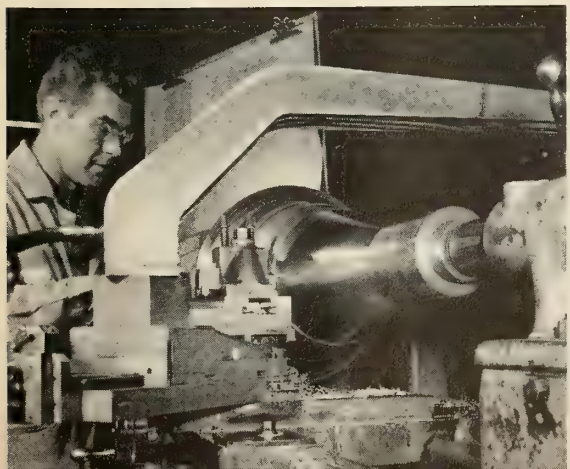
To meet these vital defense needs on a competitive basis has required the use of the most modern contouring equipment, along with good machining practice. The Monarch air-gage tracer lathe is an example of the type of tracer-controlled precision contouring machine that has been found best suited to the needs of missile and rocket contractors.

The services of resourceful and diversified manufacturers in producing missile components has contributed greatly to our nation's defense programs. However, a major factor in the ability of these manufacturers to produce lies in the development work and the advances which have come from the machine tool industry.

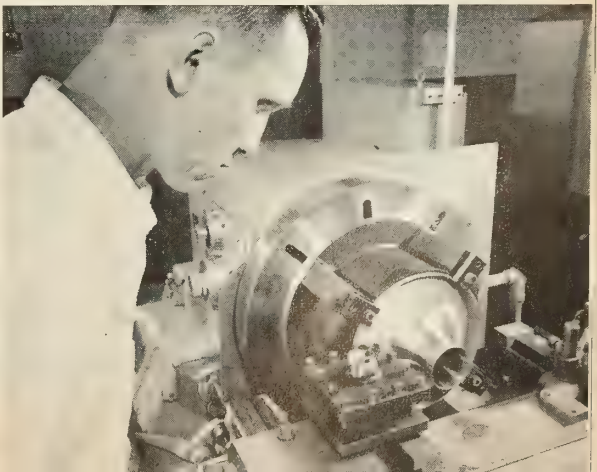
"Until they start building square rockets, an engine lathe of 48-inch, or more, swing plus air-gage tracer equipment for precision contour control will still be the tool most needed in the production of guided missiles." These were the words of a man who has been intimately associated with the business of producing rocket hardware practically from the outset of our nation's program of missile development. He is head of a concern which currently has contracts for machining parts for over 15 major missiles.

We already have available in our current tracer lathe designs most of the features that missile machining experts are finding essential for this exacting type of metal removal. This involves not only complex contours and ultraclose tolerances, but critical surface finishes as well. The machines are precision-built engine lathes featuring a sensitive duplicating device, called the air-gage tracer, which automatically controls contour turning, facing and boring cuts using a single-point tool.

Most components for rockets and missiles now in production, or in the advanced development stage, demand extensive machining and the application of special techniques in the contouring of complex shapes from rough forgings. Common materials are A-286, Inconel, 17-7 Stainless and heat-treated AISI-4130.



Because a missile is subjected to extensive stress under flight conditions, quality and reliability of finished components are vital considerations. Design often compels the use of materials up to their ultimate strength. This necessitates close control of machining operations so as to obtain a finished part dimensionally stable and free from residual stresses. Continued close quality control is required to meet military specifications.



The troublesome machining problems in the missile field stem primarily from the required turning of larger parts of varied contour and extremely thin wall sections. A part 30 to 60 inches in diameter with a wall thickness of 0.076 to 0.187 inch is not uncommon. The initial forging is often a solid blank and considerable metal must be removed in producing the desired contour.

Machining Practice

Machining techniques, already well established in turning jet aircraft parts from high temperature superalloys, have been effectively applied in the missile field. At Steel Products Engineering Co., for example, turbine discs for the J-79 engine are turned on right angle lathes to close tolerances, using constant surface cutting speed. A 23-microinch finish is obtained on the A-286 alloy on the finish pass. Cutting speeds of 275 fpm are used for both the roughing and finishing operations. This method is currently used by Steel Products Engineering to produce smaller parts for a missile ramjet. Grinding is eliminated, and stress re-

Representative air-gage tracer-lathe controlled machining operations. Lathes are (left) 20-inch Series 61 and Series 62 (right).

lieving after machining is unnecessary.

A major contractor in the field of missile hardware, Diversey Engineering Co., has utilized the maximum versatility of the air-gage tracer lathe in producing parts for prototypes, as well as for production programs. Nozzles, bulkheads, rings, adapters, etc., are all entirely contour turned on Monarch equipment. Exacting complex contours are obtained with the swivel slide in a single machining set-up. Tracer pressure against the template is light, thereby eliminating template wear which ensures a high degree of accuracy.

Accurate template reproduction assures built-in inspection on complex contours which would otherwise require costly gaging fixtures.

Major components for rocket motors by Reaction, Thiokol, and Aerojet General must be completely machined to a 63-microinch finish or better. Because of the complexity of these and other missile parts, grinding such shapes would be costly and difficult, if not impossible. Thus, final finish is entirely dependent on the performance of the air-gage tracer, the nature of the tooling, and the properties of the material. On heat-treated and age-hardened materials a 20- to 26-microinch finish is easily obtained on these lathes with carbide tooling.

Many smaller shops, such as United Aero Products, have shared in the responsibility of producing components for development models to meet engineering test schedules. Tracer templates can be changed quickly from one job to another, and design changes can be made directly on the flat template, thus eliminating costly delays for later production orders on difficult parts.

A new application for the air-gage tracer lathe has been in the area of machining large, thin-walled, nonmetallic parts. Fabricated components, such as nozzle liners produced by Haveg Industries, all require finish machining to close tolerances so that they properly blend the contour into the metal section in which they are mounted. These temperature-resistant materials are somewhat abrasive and are normally turned at reduced cutting speeds, using light feeds and harder tungsten grade carbides.

Tooling Practice

In practice, contouring of today's missile parts normally starts with the roughing out of the basic forging on heavy duty lathes. This involves the removal of one-half to three-quarter-inch stock on a side. The roughed blank is then given a thorough hardening or solution treatment under strict metallurgical control.

Material requirements vary, but the most common alloys currently used are AISI-4130 and C-1020 steel. The specified hardness for alloy steels after heat treatment normally is R_c 32/36. Solution-treated, high-temperature alloys are machined in the range of 300-360 Brinell. In this hardness range, these alloys are very abrasive and difficult to turn. Finish turning is accomplished with K7H carbide, using light feeds and surface speeds of 200 to 280 fpm.

A knowledge of the properties and machinability of the material is a major requirement in machining the many new metals used in the missile field. Specific cutting speeds and feeds are required for each alloy. Some plastics and nonferrous alloys may be machined at high speeds; while the superalloys, including titanium, plutonium, 17-7Ph, and Niomic, all require cutting speeds under 100 fpm. A new addition to the above group is heat-treated tool steels in the range of R_c 42/56.

General turning practice involves selecting the proper cutting speed, which is determined by the machinability of the alloy, and then balancing the feed rate in relationship to the rigidity of the workpiece and capacity of the machine. Finishing cuts are sometimes limited by thin wall sections and by the extreme hardness of the material. Roughing feeds generally range from 0.010 to 0.016 ipr. Finishing feeds depend on the finish requirements and the tendency for chatter to occur. The high-temperature alloys require the use of positive rake tools with minimum nose radius, and show more tendency to work harden. The depth of cut on finishing normally is held below 0.040-inch.

Monarch is prepared to offer tracer-controlled lathes of greater swing as the needs of missile manufacturers ultimately increase. However, our newest design of lathes now offers many of the features which machining experts are finding essential for this exacting type of metal removal.

In addition, we and other machine tool manufacturers are carrying on considerable research on the machining of new alloys and on developing new contouring techniques. Basic metal cutting studies have already shown the correct cutting conditions and tool geometry for profiling critical parts.

Engineering and demonstration facilities are available to help contracting firms obtain a working knowledge in the contour machining of metals. Combining good machining practice with air-gage tracer equipment results in one of the most important teams in our rocket and missile program.★

Manned Re-entry: A Technical Barrier of the Past?

While *Laika, Sputnik* II's space passenger, was still alive and orbiting the earth several hours after launching, the world asked: will the dog be returned to earth, and if so, how?

It was this concern over *Sputnik's* passenger that spotlighted the tremendous advances that have been made by industry and government research centers in the field of missile re-entry research. Representatives of two companies engaged in re-entry research were unshakably convinced that the present advances in the state of the art made it feasible to return *Laika* to the earth alive.

The advances are basically the result of ballistic missile nose cone re-entry research. The announcement that the Army had solved the re-entry problem by returning to the earth intact the nose cone of a *Jupiter-C* test rocket was the first report of this breakthrough.

Two distinct but basically similar approaches have been employed by the Army and the Air Force.

The Army nose cone used a combination of devices many of which were for the sole purpose of retrieving the cone from the ocean. Cook Electric Co. of Skokie, Ill., developed a parachute-drag device for reducing the re-entry velocity. Device was either a series of rip-away parachutes, increasing in size as velocity was reduced, or a single parachute controlled in resistance area by a reefer apparatus that released the parachute as a function of velocity and drag.

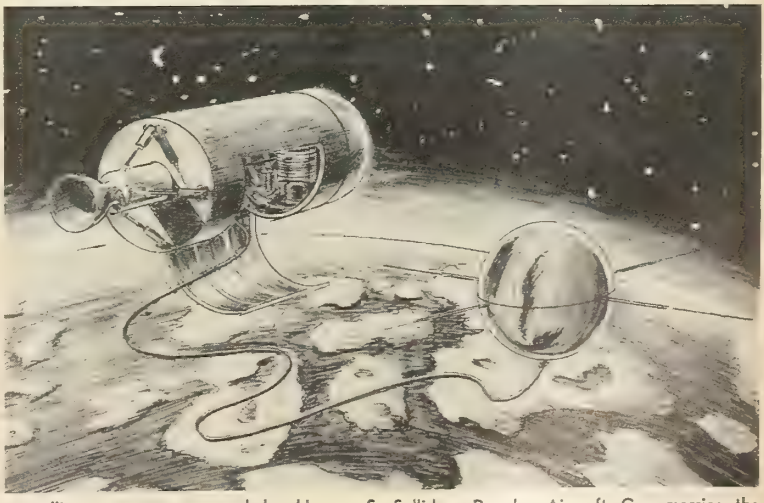
The nose cone was manufactured by Cooper Development as a machined stainless steel unit. This was covered with a Rockide ceramic coating by Norton Abrasives.

Avco, engaged in Air Force nose cone research, may be employing the parachute technique, but unlike the Army technique, the "parachute" utilizes steel for overcoming high temperatures.

For example, a satellite weighing 250 pounds (the approximate weight of the *Sputnik* II payload) could be returned safely with a stainless-steel drag area of approximately 500 square feet. By opening the parachute at the satellite's perigee—say 150 miles—the payload would return to the earth in about 15 orbits. Inhabited vehicle deceleration must be held below nine g's.

General Electric has been employing the drag-brake principle for deceleration, orientation and separation of the "live" portion of the nose cone. Basic difference in the techniques apparently is the velocity of re-entry. Avco and Cook techniques indicate subsonic velocities while the GE approach would probably be high supersonic.

A. J. Eggers of NACO has proposed a satellite-recovery technique with a ceramic-coated hemispherical satellite of 10-feet diameter that would enter the atmosphere and decelerate at less than eight g's. Satellite weight would be in the neighborhood of *Sputnik* II or approximately 1200 pounds. After subsonic velocities had been reached, parachutes would lower the satellite to the earth.



Two other firms actively engaged in re-entry research are the Arnold Engineering Development Center and the Lockheed missile systems division. Both employ far-hypersonic shock tubes for model "flight" tests.

A satellite recovery proposal by Horace S. Solliday of Douglas Aircraft Co. is a representative engineering approach to the problem. Solliday's design would use the third-stage launching rocket as the initial re-entry phase vehicle. The satellite would be ejected from the rocket for making scientific measurements while joined to the rocket by a cable. Later, the satellite is winched in and the rocket oriented for retrofiring the engine for deceleration.

The orientation and retrofiring of the rocket would be a very complex and difficult operation for an unmanned satellite. In addition, 50-80 per cent of total weight to be decelerated would be needed as rocket fuel.

The rocket, which would have an ICBM-type nose cone, would again be turned around and exposed to the high-temperature shock layer. After ribbon chute speed is reached the satellite would again be ejected, this time by explosive action, to enable it to penetrate the supersonic slip stream. Finally, by ejecting a series of increasing-diameter parachutes, the payload would be lowered to the earth undamaged.

Russia announced the solving of the re-entry problem by using "sweating walls" and a form of ceramics called "metallo-ceramics." Composition is silicon and 10 to 20 per cent cobalt powder.

A satellite recovery proposal by Horace S. Solliday, Douglas Aircraft Co., marries the satellite and final-stage rocket for launch, scientific measurements and during re-entry.

Mach 17 Shock Tube Tests *Polaris* Design

A 13,000 mph shock tube for testing ballistic missile design is in operation at the Lockheed missile systems division research and development labs at Palo Alto, Calif. The 40-foot-long tube is being used for advanced design work on the *Polaris* flat ballistic missile.

The tube, made of stainless steel, has an inside diameter of three inches and walls an inch and a half thick. Two separate techniques will be employed in the tube to produce shock waves. One will be the use of high-pressure helium. The other will be the use of a mixture of hydrogen and oxygen, which will be triggered into explosion by a spark.

The shock tube works on the build-up of gas under pressure at one end of the tube which ruptures a thin diaphragm when the pressure reaches a certain level. The high-pressure gas then speeds down the tube behind a hypersonic shock wave.

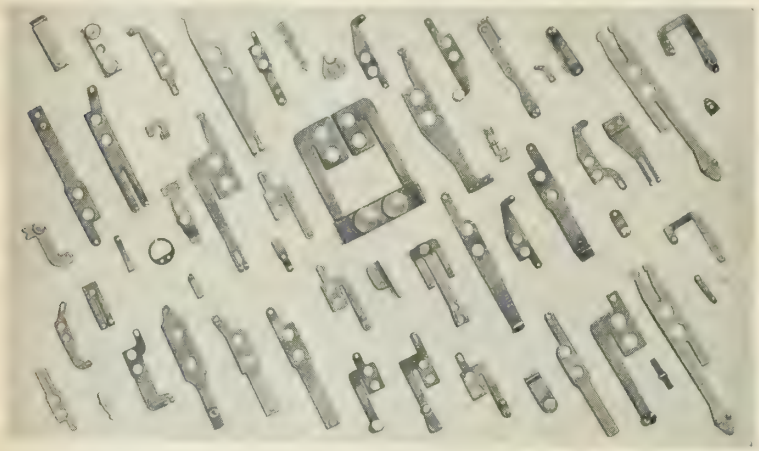
Lockheed scientists will study heat transfer, shock wave shapes and other details of airflow around missile models. In addition they will perform basic research in high temperature gas dynamics.

Lockheed is the missile system manager of the *Polaris*, a solid-propellant weapon to be launched from submarines, and provides technical direction to several other firms working on the program.

Martin Creates *Vanguard-Titan* Division

The Martin Co., has formed a new division for speed up of the on-the-spot arrangements for launching both *Vanguard* and the Air Force *Titan* ICBM.

G. T. Willey, the company's corporate vice president-manufacturing, will assume additional duties as vice president and general manager of the new division. This division will have equal status with Martin's Baltimore, Denver, and Orlando divisions. He will have charge of all Martin activities in the Patrick Air Force Base and Cape Canaveral area, including the continued testing of latest versions of the *Matador* surface-to-surface missile.



Martin's *Titan* project, involving a contract in the amount of $358 million for the second of two mutually supporting Air Force ICBM programs, got under way early in 1956 with construction of the company's Denver division near Denver, Col.

Ceramic Radomes Designed for Re-entry

Gladding, McBean & Co., has just completed the first ten prototype high-alumina ceramic radomes designed to withstand the high temperatures generated when ballistic missiles re-enter the atmosphere.

First, many formidable obstacles had to be overcome. The major difficulty lies in the fact that a radome must be as transparent as possible to radar waves. This meant finding a material that would have the right electrical properties as well as the required temperature resistance and strength. More important, it meant devising a manufacturing method which could hold the wall thickness to a tolerance of 0.001 inch.

The technique finally worked out by Gladding, McBean starts with high purity alumina (Al_2O_3) with which is mixed a small amount of organic binder to give some strength before firing. This results in a final body of 97 per cent alumina. This is made up in the form of a slurry which is prayed on a chrome-plated steel mandrel with a spray gun. Later fabrication operations subject the radome to a pressure of about 30,000 psi and temperatures of above 3000°F.

CONTACT TRICON FOR CONTACTS

Tricon furnishes contact assemblies to the electro-mechanical industry and specializes in missile control applications. At Tricon you have a team of specialists in the manufacture of switch and relay spring-blade components, as well as precious metal contacts and assemblies.

The FINE PARTS WELDING AND BRAZING DEPARTMENT at Tricon is available to semi-conductor manufacturers for the precision assembly of diodes and transistors. Make a good connection and contact Tricon for contacts.

Major *Hawk* Subcontractor Is Northrop Aircraft

Northrop Aircraft holds contracts amounting to approximately $20 million which were awarded by Raytheon for work on the *Hawk* surface-to-air missile sytem. Contracts are for research, development and manufacture of airframe components and support equipment for the *Hawk*, including appropriations for facilities, engineering services and procurement.

Raytheon Manufacturing Co., Andover, Mass., is the prime contractor for Army Ordnance, with Northrop in the position of major subcontractor. Northrop has the responsibility for structural integrity and aerodynamic performance of the missile, design and fabrication of major airframe portions, the mobile launcher, missile loader, pallet and reusable container.

About 70 per cent of the total dollar volume of the Northrop work on the *Hawk* is for support-equipment items such as the integrated launcher and missile loader for field use. The integrated loader-launcher is said to employ an extremely lightweight and compact design concept. It is self-propelled, can ford streams up to 30 inches in depth, and could

Circle No. 54 on Subscriber Service Card.

float if required.

Manufacture of portions of the *Hawk* is underway at the company's Anaheim, Calif., facility, while engineering activity is under way at both the Anaheim and Hawthorne facilities.

Specifically designed for defense against low-flying aircraft, the *Hawk* uses a Thiokol solid-propellant rocket motor.

AP&C Production Exceeds Demands

HENDERSON, Nev.—America's only large-scale producer of high-energy ammonium perchlorate is still undergoing the gradual transition toward large, high-performance solid rockets. Virtually all U.S. high-performance solid rockets utilizing composite propellants use ammonium perchlorate as the oxidizer.

The large, Navy-financed, American Potash & Chemical Corp. plant is still operating below its estimated 1200-tons-per-month ammonium perchlorate (AP) capacity.

The plant has had a rough time selling AP. The market was originally small and because of the low production, nobody wanted to swing toward this item. Despite shutdowns, however, the employment figure for the Henderson operations has grown from 75 in 1945 to over 400 at the present time. Present operation theory appears to be, work on the smallest efficient schedule and/or make limited large runs and stockpile.

Orders are still sporadic for AP but the trend for larger solid missiles may at least make the future more certain for AP. As yet, the American AP market for missiles has not been pinched by a competing Norwegian firm.

Atlas Engines In Production At Neosho

Rocketdyne's Neosho, Mo., plant began production last month on engines for the *Atlas* ICBM.

Atlas work at Neosho supplements extensive research and development activities being carried out on the ICBM program at the main plant of Rocketdyne in Canoga Park, Calif., and at its nearby propulsion field.

The recently occupied plant is scheduled to become a prime source for missile propulsion systems during the next year. It has been in build-up production of the developmental engine and components since February. Testing began at its 200-acre field complex early last month.

West Coast Industry

By Fred S. Hunter

An illuminating example of today's weapons trend is Northrop's report that 57 per cent of its present $216-million backlog is in guided missiles and related equipment. Northrop has two big missile programs in the *Snark* SM-62A and a major subcontract from Raytheon on the Army *Hawk*. Its Radioplane Division also is engaged in development work on a classified Air Force missile weapon system. Pointing out that it has demonstrated its long-range accuracy in numerous successful test flights, Northrop anticipates the *Snark* will continue to occupy a significant position in its weapons roster for several years. Approximately 35 per cent of the company's total work force is engaged in the *Snark* program.

•

Even though it is subsonic (Mach .94), the *Snark* is a more sophisticated bird than many people think, and has a growth element built into it. Its maximum altitude is in the range of 60,000 to 75,000 feet. Performance of its Northrop-designed *Mark* I celestial and inertial guidance system is unimpaired by night or bad weather. It is designed to carry a nuclear or other priority warhead and incorporates a separable nose cone. The company is able to claim that it has "the longest range and the greatest accuracy of any missile in the free world today." The missile, now in production and scheduled to become operational in early 1958, is the "A," but there also are "B" and "C" versions in the program.

•

Delays in settling zoning variances and other details have held up the start of construction on Hughes Aircraft's new $6-million plant for its ground systems division near Fullerton. But the division is functioning in several leased structures, including two located at the Fullerton Airport. Hughes purchased 430 acres of Sunny Hill ranch, a 650-acre tract near Fullerton, for the project. The remaining 220 acres are to be used for a housing subdivision and 20-acre shopping center.

•

President George I. Long reported in San Francisco that Ampex Corp. has revised its projected sales for the fiscal year to April 30 down to $27.5 million from $29.8 million because of the slowdown in defense spending, which, he said, has hit the electronics industry, too. Ampex also sees its September 1 payroll of 2100 cutting back by about 240 by the end of the fiscal year. But for the long pull there will continue to be substantial spending "particularly in the missile area in which we are vitally interested," Long said.

•

We'll make one comment on *Sputnik*, and then subside. There can only be one first. Columbus was such a first. Others followed in bold journeys to America, but who remembers them? The Russians marked up a first with *Sputnik*, and it may very well be in the same historical category as Columbus.

•

Rocketdyne's new film on rocket development history, "Road to the Stars," is about as strong a nontechnical pitch for liquid propellants as it is possible to make. It figures, of course. Rocketdyne is in the business. The film, however, sets high standards.

•

Aerojet-General reports its investment in new facilities in the next year will total $5 million.

Painting by Chesley Bonestell from the book *The Exploration of Mars* by Willy Ley, Wernher Von Braun and Chesley Bonestell, published by Viking Press ($4.95). ©C.B.

How do you control temperature on space ships?

The answer is — you don't. The controls do — controls that act many times faster than a man can react. Controls are the real key to all problems beyond sound and heat barriers.

It would be easy to list here the part Fenwal has played in the ever-progressing field of aircraft temperatures, over-heat detection and other controls. But this would only be repetitious. The aircraft industry is well aware of it.

Rather, Fenwal prefers to restate its position for the future. Fenwal is prepared by *experience . . . with equipment . . .* and *through its manpower* to work ahead with you whatever the stage of your current problems. Of this you may be sure: Fenwal's present equipment already enables the most modern advances in its field.

This is well typified by Fenwal's advanced position in power plant controls through thermocouples, harnesses and special engine accessories.

To enlist Fenwal's ability to help meet *your* present and future control problems, write Fenwal Incorporated, Aviation Products Division, Ashland, Massachusetts.

Fenwal *Controls Temperature . . . Precisely*

THE VITAL DIFFERENCE

SEAL-LOCK *

Now... a self-locking foolproof, truly REUSABLE FITTING

for high temperature Fluoroflex®-T Hose

HERE AT LAST – THE IDEAL FIELD ATTACHABLE FITTING:

Triple-locked to hose – cannot blow off.
Dynamically sealed – not once, but twice – cannot leak.
Tamper-proof – cannot be loosened accidentally or by vibration.

WILL PERFORM AS DEPENDABLY AS IF FACTORY ASSEMBLED

by trained mechanic under closest supervision – yet
Easily assembled – flared skirt on socket protects hose and hands.
Needs no special skills – no torque wrench required.
Foolproof – parts fit only one way – the right way.

AND IT IS TRULY REUSABLE AGAIN AND AGAIN

Hardened parts keep extra safety factors intact.
Lines made with Seal-Lock Fittings which have been disassembled and reassembled many times still function as well as originally.

ANOTHER PRODUCT OF RESISTOFLEX INGENUITY,

to the standards of Resistoflex Reliability,
for your safety and that of your customers!

Send for Bulletin RF1.

And remember, Fluoroflex-T hose assemblies are now available with either reusable or permanently attached fittings.

*®Fluoroflex is a Resistoflex trademark, Reg. U.S. Pat. Off. *Trade Mark Patent applied for.*

DECEMBER 1957

EEMCO DELIVERS

. . . a completely new stabilizer actuating system for one of the latest jet transport aircraft 119 days after receipt of contract!

Again proving the advantage of specialization in the field of designing and producing actuators and motors for aircraft and missiles exclusively, **EEMCO** takes pride in having assisted one of the large airframe manufacturers in the production of a new type jet transport aircraft in record time by supplying the **EEMCO** actuating system illustrated less than four months from receipt of order.

Capable of handling a total operating load of 15,000 lbs. in tension or compression on both jacks, this new **EEMCO** actuating system corrects the aircraft's stabilizer in flight. It will operate many times during an average flight, therefore hundreds of thousands of operations will be performed during the life of the unit. **Extreme reliability** of the system was therefore a prime specification in the contract.

The 28-volt motor is equipped with radio noise filter, magnetic clutch and brake, and an integral gear box with dual output shafts that drive the synchronized screw jacks at loads up to maximum capacity. Ultimate load on each jack, which is equipped with non-jamming stops, is 50,000 lbs. tension or compression. The jacks, with a stroke of 8.25 inches at .3 inch per second at maximum load (15,000 lbs.), are equipped with an auxiliary reduction for a control mechanism.

The proven elements of this efficient **EEMCO** actuator system, motor with gear box and the jacks, can be adapted for other uses individually or in similar assemblies.

Your inquiry is invited.

SPECIFICATIONS

Voltage: 28-volt DC
Stroke: 8.25 inches
Speed: .3 inch per sec. at maximum load
Maximum load: 10,500 lbs. on each jack, tension or compression
Maximum system load: (both jacks) 15,000 lbs.
Ultimate load: 50,000 lbs. on each jack, tension or compression — 100,000 lbs. total
Military Specs: Assembly designed to meet MIL-M-8609, MIL-A-8064 and MIL-E-5272A
Features: 1. Jacks are equipped with non-jamming stops.
2. Single power unit drives the jacks at synchronized speed.
3. Jacks are equipped with auxiliary reduction for a control mechanism.
4. Motor has magnetic clutch and brake.

special features

Are radical changes in design concepts necessary to solve reliability problems?

Two engineers who helped design the higher reliability into the Navy's *Terrier* system discuss the problem of reliability design. Russell R. Yost, Jr. and Fred Dreste, of Motorola, Inc., give a clear picture of how quality can be designed into electronic components (page 114).

What is the best method for training personnel to operate high-performance missiles?

Since production-line missiles are not designed for frequent assembly and disassembly by students, they often require extensive overhaul that rivals a new missile in cost. Solution of this problem is the synthetic missile, which is the concept of the Navy's Training Devices Center at Port Washington, New York. J. Gordon Vaeth and Lt. Cmdr. John Huson explain the concept (page 119).

What can we expect of communications systems in outer space?

Recent test vehicles have brought back information about the conditions we can expect to encounter—communication-wise—in space. AAP Electronic Editor Henry Steier gives a run-down on the question in his article on page 121.

cover picture:

This recording optical tracking instrument is being used by the Air Force at Melbourne, Fla., for photographing the flight of missiles fired from Cape Canaveral. It is manufactured by Perkin-Elmer Corp., well-known for its work in this field. Working as part of the overall missile-test-data net, the Melbourne installation will be able to more accurately position missiles than methods previously in use. Controls on the telescope will be adjustable by use of a hand-control stick. The ROTI is complete with its own electronic and mechanical equipment, computers, dark room for film development, maintenance section and air-conditioning system. Automatic correction will be made for parallax and for the earth's curvature. The unit may be operated through remote-control by range personnel, and then operation will be transferred to the ROTI operators when the missile comes into sight.

MIRACLE IN MINIATURE

Observation and control of amphibious and airborne landings.

Close observation of jet or piston engine test performance.

Surveillance of assembly areas and movements of forces.

Observation of danger areas, where exposure would involve danger to personnel.

Brand new! RCA "Telemite" (model JTV-1) a 1-pound ultra-miniature television camera, makes possible direct observation of sites and events never before accessible by TV

It fits lightly into the hand; it can be carried in a pocket; it weighs about a pound; it will go places too small for ordinary cameras, too dangerous for man; it will observe without being conspicuous; it may be mounted on a tripod, fastened to wall or bulkhead, hand-held by a pistol grip. Size: 1⅞" x 2⅜" x 4¾".

By means of a transistorized circuit and the new RCA half-inch Vidicon, the "Telemite" actually surpasses standard Vidicon-type industrial TV cameras in sensitivity. It produces clear, contrasty pictures with a scene illumination of 10-foot candles or less.

The "Telemite" operates with up to 200 feet of cable between it and the control monitor, and this distance can be further extended by using a repeater amplifier. This is the first TV camera to employ photoelectric sensitivity control, which provides automatic adaptation to widely varying scene illumination.

washington briefs

WASHINGTON IS WATCHING THE HANDWRITING ON THE WALL. Many small firms in the electronics industry are experiencing very rough water in the wake of defense cutbacks—*Sputnik* notwithstanding. The administration knows that it is in a jam. There is no question but that many markets for small electronic-specialty firms are drying up. The rise in future defense spending will not come in time to prevent considerable hardship. Aircraft companies, looking for their own business, are cutting the business that keeps many small contractors going.

NEARBY MARTIN CO. WOULD LIQUIDATE and go out of business if peace broke out tomorrow. This statement by Martin's president shows the basic problem now affecting subcontractors tied to companies like Martin. The statement by Martin's president was made in light of the company's total commitment to defense contracts.

THE PENTAGON IS PUSHING THE ICBM DEW LINE PROJECT now being planned by U.S. and Canada. Research studies are under way which will determine the feasibility of such a line. An American-loaned radar has been installed in Saskatchewan and the Pentagon is watching the results of research stemming from use of the radar. It has long been acknowledged that the present DEW line is inadequate for ICBMs.

THE NAVY DEPARTMENT IS IRONING BUGS OUT OF *POLARIS* with use of a new electronic computer capable of "flying" the missile while still on the drawing board. Known as PACE, the computer is being used by Lockheed engineers to eliminate unworkable designs.

DEFENSE DEPARTMENT IS DELUGING THE PRESS with news, any news, about recent rocket developments in the U.S. The latest is an electronic instrument that can analyze an instantaneous sequence of chemical reactions such as take place in the explosion of rocket fuels. Called a "time-of-flight mass spectrometer," the device is being produced by Bendix Aviation Corporation.

ARMY SIGNAL CORPS HAS GREATLY INCREASED RADAR POWER by development of an amplitron tube, which doubles the power efficiency of the magnetron tube presently being used in many radars. This is one of a series of recent steps that considerably boost the usefulness of our radar.

THE AIR FORCE HAS ESTABLISHED unusually high requirements for instrumentation cable, 11 miles of which is now being produced by Rome Cable Corp. for gauging performance of the *Titan* ICBM's rocket engine.

NAVY DEPARTMENT NOTIFIED its major contractors to sharply limit hiring of new employes, except those essential to replace key personnel. The Navy asked that hiring of other employes be cleared by BuAer first.

AIR FORCE'S AIR MATERIEL COMMAND has awarded a contract for "side looking" radar to Texas Instruments, Inc. The system presents a three-dimensional picture of terrain, and a continuous-strip photo is made from the radar scope.

MARTIN'S NEW ELECTRONIC COOLING SYSTEM has impressed Pentagon officials considerably. The system uses water to cool components. The new technique affords an essential constant temperature of components, even though the outside temperature climbs more than a hundred degrees.

Offer a wide range of performance characteristics to meet your switching, regulation or power supply requirements

These nine Delco Radio alloy junction germanium PNP power transistors are now in volume production. They are characterized by high output power, high gain, and low distortion. And all are normalized to retain superior performance characteristics regardless of age.

Check the data chart above—see how they fit your particular requirements in current switching, regulation or power supply. Write for detailed information and engineering data. Delco Radio maintains offices in Newark, N. J. and Santa Monica, Calif. for your convenience.

Long-range Optics Track Missiles

Photographing a ballistic missile from the time of launch until it is over 100 miles down range is the task of an optical tracking instrument recently installed at Melbourne Beach, Fla. The instrument called ROTI *Mark* II (Recording Optical Tracking Instrument) will soon go into operation as a part of a guided missile data-collection station of the Air Force Missile Test Center tracking net.

ROTI *Mark* II will permit the Air Force to measure the position of a missile moving in space and time with a greater accuracy than has heretofore been possible. The ROTI series of instruments were designed, developed and are being built by the Perkin-Elmer Corp., a leading supplier of such systems. The *Mark* II unit will be used in conjunction with the firings of *Jupiter, Thor, Polaris, Atlas, Titan* long-range ballistic missiles.

The Melbourne Beach ROTI Data Collection Station will operate as an integral part of the Patrick range communication and tracking net. Information from radar and other communication nets will be fed into the station when a missile is fired. Computers at the station will convert this into information that will activate and adjust the ROTI. Corrections will be made automatically for parallax (difference in distance and line of sight from the radar to the station), and for the earth's curvature. ROTI will be focused automatically and will also make automatic corrections as the sky background changes.

The ROTI station can be operated by remote control or by range personnel employing "aided tracking." When operated by range personnel, the same information will be fed into the system. However, when the missile comes within sight, the operators will take over. With aided tracking, the operators need make only the simplest mental calculations and the slightest physical movements to follow the missile. The slightest hand pressure on a stiff-stick control will enable the operator to adjust the acceleration, velocity and position of the telescope.

The ROTI station is a complete, self-sufficient unit, with its own electronic and mechanical equipment, computers, dark room for developing film, maintenance section and air-conditioning system. The tower housing ROTI is very similar to that of an astronomical observatory.

Instruments Analyze Ion Flight Time

A new electronic instrument that can analyze an instantaneous sequence of chemical reactions, such as takes place in explosion of rocket fuels, is in production. The new device, called a "Time-of-Flight Mass Spectrometer," will have numerous applications in the science of missiles and rocketry.

It can complete a chemical analysis in one ten-thousandth of a second, operating on the principle of instantly identifying vaporized gases, liquids and solids (including metals) by revealing their respective molecular masses.

The heart of the new instrument is a four-foot metal vacuum tube that scientists call an "ion gun." Ionized molecules of the elements being analyzed are pulsed like radar signals from one end of the tube to the other and their speed, or "time of flight," is measured electronically and appears as a wave pattern, or spectrum, on an oscilloscope.

Components Reliability Plagues IRBMs, ICBMs

All the fundamental scientific problems for producing long-range ballistic missiles have been solved, Dr. Simon Ramo, executive vice president of the Ramo-Wooldridge Corp. recently announced. He said the major problem of most weapons systems which continues to plague the ballistic mis-

MISSILE TEST DATA TRANSCRIPTION AND ANALYSIS

The transcription, analysis, and evaluation of ballistic missile test data is one of the important aspects of R-W's system engineering and technical direction responsibility for the Air Force Ballistic Missile Program. Utilizing the facilities of R-W's Data Reduction Center, test data are transcribed and reviewed to determine performance characteristics and confidence levels.

The following positions in this rapidly expanding field are currently open on the R-W staff:

Senior analyst to direct mathematicians, engineers, and technical aides in missile test analysis projects and to participate in overall evaluation of missile systems performance. The test information originates from optical, radar, and telemetry instrumentation. Particular emphasis is placed upon electronic analysis of vibration data.

Engineer with wide experience in telemetry operations. The position volves planning and directing the conversion of telemetered data into forms appropriate for the analysis of weapon systems performance. Experience in the design, maintenance, and operation of telemetry data transcription and electronic vibration analysis equipment is desirable.

Engineer experienced in the utilization of missile test data transcription equipment. This position involves the planning of equipment schedules, with various research and industrial organizations, for the conversion of missile test data. A thorough knowledge of the capabilities and limitations of telemetry transcription and electronic vibration analysis equipment is desirable.

Inquiries should be addressed to: **Mr. J. H. Armitage**

The Ramo-Wooldridge Corporation

5730 ARBOR VITAE STREET • LOS ANGELES 45, CALIFORNIA

sile is the achievement of component reliability.

The approximately 300,000 separate components which go into a ballistic missile must undergo an extensive and intensive test program before a missile flight.

To illustrate the importance of the testing process in providing the exceptional reliability demanded by every part and mechanism of a ballistic missile, Dr. Ramo pointed out that each of the 300,000 components which go into an IRBM or ICBM is first tested individually. It is then fitted into a combination of 75 or 750 components.

Sapphires used for Infrared Detectors

Synthetic sapphires are playing an important role in the fast-growing field of infrared instrumentation. The unique characteristics of high-transmission properties at elevated temperatures—its strength and corrosion and abrasion resistance—make it an ideal infrared-system material.

As a heat sink, sapphire provides high electrical resistance and high thermal conductivity—both important qualities for fast, sensitive response.

As a window, sapphire is used in detector applications which require transmission of the visible spectrum with a cutoff of about 6.0 microns in the infrared band. In addition, sapphire is readily sealed to metals and ceramics, thus it can be made of any electronic assembly.

Synthetic sapphire is grown as a boule in a small oxy-hydrogen furnace in which aluminum oxide in power form is fed through the flame and the melted material collected in crystal form on a pedestal. Single crystal sapphire windows are fabricated from annealed white sapphire disk boules in diameters from one-half inch to five inches.

Sapphire components are being produced by the Linde Co. division of Union Carbide Corporation, New York, N. Y.

Cameras to Track Earth Satellites

The task of photographing a golf ball thrown from a plane at 60,000 feet is an apt description of the job assigned to the 12 satellite-tracking cameras that will be used to follow the U.S. satellite when it is launched sometime in the near future.

The three-ton, Schmidt-type wide-angle telescope cameras, designed for the Smithsonian Institution Astrophysical Observatory, will be located at 12 stations throughout the world. They are all on the orbit the satellite is expected to travel, and will be able to photograph the "moon" approximately once a week.

A master control unit containing a crystal controlled clock, a master Cathode ray tube calibrated in time increments and a direct numerical time readout unit will supply control information to the camera and its operators. Provisions have been made for slave tubes and a slave clock as may be required.

Talos Features Traffic-light System

The *Talos* surface-to-air missile features a "go, no-go" test system that tells when the weapon is ready for firing. *Talos* uses the automatic test equipment designed and built by the York, Pa. division of Bendix Aviation to determine whether all of its systems are operating properly before it is launched.

The results are recorded by lights, indicating which components have passed, or failed. A master light on the system called *Talos* Tactical Test Equipment (TATTE), will give the go-

ELECTRONICS EDITOR
for Missiles and Rockets

MISSILES & ROCKETS is seeking an additional electronics editor for its new Missile Electronics section. Applicant must be experienced and outstanding technical writer-reporter. Knowledge of electronics and missile fields essential. Engineering background preferred. Please give salary requirement. Write:

Robert H. Wood, Editorial Director,
American Aviation Publications
1001 Vermont Avenue Northwest
Washington 5, D. C.

Guiding a missile, or speeding flight and flight environmental data back to control and tracking centers, is too much of a job for conventional communication systems. Supersonic speeds call for lightning fast data communications, coupled with the utmost reliability.

Capitalizing on the ease of converting messages into digital form, Motorola scientists and engineers have developed a number of Data Link Communications Systems suitable for piloted aircraft, as well as missiles.

NERVE CENTER FOR DATA LINK SYSTEMS

With Data Link Systems, messages that have been translated into on-off pulses can be transmitted by any of the common modulation schemes with a suitable carrier. The transmitter can be air-borne, ship-borne, or land-based. Received messages are amplified, decoded, and transformed into a form suitable for display, or stored for some future time, or used for direct control through auto pilots, for example.

One of the Data Link Systems designed at Motorola utilizes an all-transistor converter-coupler, packaged in modular form. The total system consists of eight modules, each approximately 4" x 8" x 1½". The fully transistorized circuitry is of the highly reliable diode-matrix type logical circuitry used in many digital computers. The switch type transistors employed are a product of the Motorola Semi-Conductor Division. Indicative of the stringent testing program to which the transistors are subjected is a 1000-hour life test at 85° C.

For another Data Link program, Motorola has designed a system featuring resolver-type outputs. A single time-shared servo amplifier positions anyone of the five resolvers in accordance with commands from the ground transmitter.

These two Motorola Data Link Systems aimed at solving one of the important communication problems of the missile age are examples of the complex programs conducted by Motorola for varied military needs.

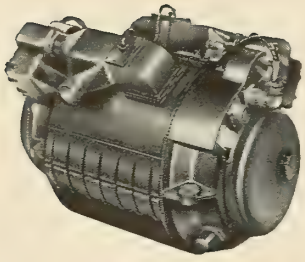
ahead, once all components have passed inspection. This automated test equipment reduces the technical training requirements of military personnel assigned to the missile.

Talos was the first missile to employ a dual guidance system, resulting in precise accuracy at both short and long ranges. In addition, the *Talos* development program also pioneered the introduction of atomic warheads into antiaircraft missiles. *Talos* is approximately 20 feet long, and 30 inches in diameter. It weighs about 3000 pounds. The missile is accelerated to supersonic flight by a solid-fuel booster rocket about 10 feet long. The booster rocket is jettisoned when the missile reaches cruising speed.

Guidance Plant Eliminates Vibration

The world's most vibration-proof slant for the development of missile inertial guidance systems has opened in St. Petersburg, Florida. It has been so thoroughly shockproofed—through unusual scientific and construction techniques—that vibrations so small they would barely "tickle a fly's foot" can be measured inside its antiseptically clean testing laboratories.

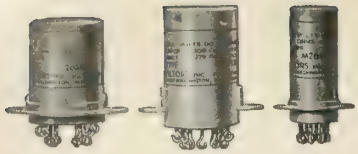
The $4.5-million structure was erected by Minneapolis-Honeywell Regulator Co. to develop the most advanced type of inertial guidance systems yet devised for missiles and rockets. Inertial guidance is a navigational concept that permits automatic guidance—of intercontinental ballistic missiles, for example—without reference to radar, radio beam guidance, star tracking or human pilot.



Exide Creates Missile Department

Exide Industrial Division of the Electric Storage Battery Co., Philadelphia, Pa., has created a new department to concentrate special company efforts in the rapidly growing guided missile field.

Called the missile applications department, the new unit will handle all phases of development, engineering, manufacturing and sales of missile batteries.



Heretofore, most of Exide's activities in the missile battery field were handled through regular departments. Effect of the reorganization is to merge all such activities into the one new department under the administrative direction of General Manager M. G. Smith.

by Henry P. Steier

INTEREST IN GRAVITY PHENOMENA AND THEORIES IS GROWING. At the annual Gravity Day meeting of Gravity Research Foundation, New Boston, N. H., George M. Rideout, president, reported an attendance growth from 22 in 1949 to 178 in 1957. He pointed out that discussion of these matters "had become respectable and was no longer the basis of facetious comments." Included among attendees was Igor Sikorsky of Sikorsky Aircraft Division, United Aircraft.

AN INTERESTING EXPERIMENT was described during Gravity Day by Joel E. Fisher. He rotated two 15-inch disks, separated about four inches, at 2500 rpm while 60 alnico magnets were mounted between the disks. Magnets were parallel to the shaft supporting the disks and poles were in direction of the shafts. Rotation caused a gravimeter placed two and one-half feet above the rotor to show an increased reading of five milligals (0.005 cm/sec^2) of the normal acceleration of gravity.

Explanation of the effect is difficult, says the Foundation, and cannot be attributed to eddy currents. An iron manhole cover between the rotor and gravimeter produced no change in the gravity reading. Needed condition for producing the effect was surrounding the rotor with a massive nonmagnetic material. In this case it was a pit formed by two tons of cement blocks and slate slabs. Anyone have an idea?

SECOND WORLD CONFERENCE ON GRAVITATION was held this year. According to Agnew H. Bahnson, Jr., president of the Institute of Field Physics, physicists, mathematicians and astronomers in attendance discussed the problem of the quantization of the theory of relativity. This, they decided, at present seems the best approach to an understanding of gravity.

NEAR INSTANTANEOUS ANALYSIS of chemical reactions can be made with a new time-of-flight mass spectrometer produced by the Cincinnati division of Bendix Aviation Corp. Analysis of such reactions as rocket fuel combustion, high-temperature instability of nose cones, etc., can be made in 1/10,000th second. Device uses a four-foot vacuum tube called an "ion gun." Molecules of elements under test are pulsed like radar signals from end to end of the tube, and time of flight is measured and appears as a wave pattern on a cathode ray tube. Miniature versions are expected to be used in missiles and satellites to examine composition of "space."

IMPROVEMENT IN THE RANGE OF RADAR, communications equipment and other electromagnetic devices by "three times" is said to be possible through a breakthrough in the technology of noise-free amplification. The new device which permits this long-sought goal is called a VERSITRON by Electronics Division of Advance Industries, Inc., which produced it.

AIR FORCE SAYS ADVANCES in powerplant technology and aerodynamics has completely outstripped advances in the electronics field. Col. J. S. Lambert, ARDC, told the IRE Electronic Devices meeting in Washington, D. C., that in the matter of high-temperature problems with electronics, available materials and techniques have been exhausted. He said our electronics designs are predicated upon available and understood techniques rather than limitations of materials or basic physical laws. What is needed are new materials research, new techniques and new design concepts.

ATTITUDE OF THE AF toward future high-temperature transistors is that they will not be available in the near future and electron tubes must be used. Despite good success with gallium arsenide, indium phosphate and silicon carbide materials for semiconductors, it appears ceramic-metal electron tubes will be the best high-temperature devices available for some time.

TERRIER electronic reliability

Reliability-orientation major contributor to missile electronics reliability

by **Russell R. Yost, Jr. and Fred Dreste**

Motorola, Inc.

RELIABILITY must be designed into electronic equipment; it cannot be implanted by test and inspection, though it can be maintained by them. The early dollars invested in a reliability program are most wisely spent to originate and enforce certain disciplines in design thinking.

Several years ago Motorola, Inc. contracted to re-engineer an electronic control system employed in the Navy's *Terrier* surface-to-air missile. The redesign was aimed at higher reliability and simpler producibility.

Both aims were met. During flights of design-approval models at the Naval Ordnance Test Station, China Lake, Calif., no failure has ever been attributed to the control system. Significant reductions of factory and field checkout time have been achieved. In addition, during a two-year production run only a few—and quite minor—electrical design changes have been made.

The disciplines that paid off in the *Terrier* project can be told simply. Taken singly, they seem unremarkable. Together, they are powerful and comparatively inexpensive in channeling design effort to an impressive reward. Not as much time nor money could go into these as a reliability engineer might wish. In particular, there was no ambitious program to learn precise quantitative reliability (though estimates were kept current), nor radical departures from conventional design in pursuit of reliability. Perfection in missile controls is still so far away that reliability effort is more profitable when spent in attending to the simple tasks to be described than when given over to exact measurements.

Reliability Disciplines

A reliability coordinator was appointed at project inception, reporting directly to the project leader. He was given an engineering staff whose only concern was reliability.

The coordinator made preliminary appraisals of all components in the categories from which large component totals were expected to be drawn. These categories—tubes, diodes, resistors, capacitors, transformers and several others—are the major factors in electronic equipment failures, not because the components in themselves are peculiarly weak, but because they constitute nearly all of the component equipment. It is vital, in these categories particularly, to choose the soundest components sold.

An appraisal was made based on past Motorola experience, other manufacturers' experience and an evaluation of the vendor's engineering ability, production facilities and quality control measures—and finally on the vendor's published ratings and data.

The coordinator then published a preliminary list of components recommended to designers for most applications. These components were used in breadboards (the information gained being worth the expense), as well as in engineering and development models. An entry in the list was accompanied by Motorola-assigned tolerances and deratings, related to expected environments and to wanted component reliability.

The tolerance assigned to each component was stated separately for factory and flight conditions. Moreover, each tolerance included two values, the first expressing a nonrandom shift of the mean of the distribution, and the second the random scatter effects. (In combining such tolerances, the first values are added algebraically while the second values are added in a statistical manner.)

Finally, two such tolerance pairs, one combining all positive nonrandom shifts resulting from likely simultaneous environments, and one combining all such negative shifts, were established.

Life tests were begun for all commonly applied components in the preliminary list and for certain special components foreseen as essential to the system but expected to be unreliable. Some life tests were run with components subjected only to the initially recommended loadings, and to an environment duplicating that expected as a rule in the missile for components of that category. It bears emphasis that a component environment was estimated as it would be related to the component. It was not assumed simply as the environment which, by specification, the whole missile control had to withstand.

Even when a component's environment was duplicated in tests, however, tests at normal loadings would in some components have produced too few failures to let component mean lifetimes be calculated with worthwhile accuracy. In these categories the only meaningful test possible was a "torture" comparison of similar components from various vendors. Most damaging elements of their environment—temperature extremes, vibration and shock or humidity—were exaggerated to hasten failures.

It was not generally possible from torture test data to say what a component's mean lifetime would be at normal load and in the actually expected environment. However, torture tests were considered at least to isolate for use the strongest components sold, and so to be the best use of available test time.

Component tests led to some changes in the list of recommendations and so to some discarding of stock purchased from the initial list. Made early enough, discards are a small entry in the whole price of reliability.

In addition to circulating application data to all designers, the coordina-

tor himself reviewed all component applications in developmental circuits.

Failures Analyzed

Every component failure, in either an experimental or developmental circuit, was promptly reported to the coordinator, with the circumstances and the direct evidence of failure described. Analyzing failure reports, and where possible deducing underlying failure causes, the coordinator was impelled in some cases to change component recommendations, in others to suggest alternative circuitry or, least often, to correct suspected misapplications.

The coordinator monitored (and his approval was required on) all drawings and specifications for purchased components.

Component specifications should include tests of three types: (1) initial qualification tests, which demonstrate whether or not the component design can meet requirements, (2) acceptance tests, which briefly check each received component or (by sampling) each lot of components for freedom from gross defects, and (3) quality reassurance tests, which amount to requalification tests, and aim to expose design weaknesses which have escaped the initial qualification test because samples were statistically too few, or because of slight changes in component design.

Component specifications should include all requirements imposed by the overall system requirements even when some seem farfetched at the component level or when tests to verify compliance with them seem impossible or hopelessly expensive. When a vendor objects, the requirements can be waived if they must be, but stating them at the outset firmly impresses the vendor with the designer's problems.

Much time spent communicating with the vendor by means apart from the specification can be saved by a shorter time spent in writing a more detailed specification in the beginning.

Responsibility for specifications should be vested in a specific individual or small group, rather than scattered among design engineers.

The coordinator educated the design task leaders in rules for tolerance calculations, both to furnish them with a valuable tool and to encourage reliability consciousness in design decisions. These rules are too complex to describe in detail here, but they were based on statistics and enabled the designers to calculate system flight-performance capabilities with 99.7 per cent probability as well as similar factory-performance capabilities.

The reliability of a circuit is usually the product of the individual reliabilities of all circuit components. As components are operated more conservatively, their individual reliabilities increase, but the required component total tends to grow too, increasing the number of factors in the circuit reliability product. Bearing this in mind, circuit designers sought maximum circuit-reliability compromises between the opposed objectives of conservative component operation and a low component count.

At the start of a design it is difficult to say how an electrical tolerance placed on a whole assembly should be subdivided among the constituent subassemblies, or that of a subassembly among its components, etc. A useful rule of thumb was found to be the initial assignment of one-tenth of the overall tolerance to each "piece" of a design.

Circuits were sought which did not depend on accidental characteristics of nonlinear components, or on component characteristics not controlled by the specification for the component. For example, circuits were chosen that controlled the direct current through tubes, rather than the dc voltages applied, since tube transconductance is more stable at a specific current than at a specific applied voltage.

In a few instances a circuit was adopted, seemingly the least unsatisfactory among limited alternatives, the function of which was suspected of depending to some degree on an uncontrolled component characteristic. In these circuits special effort was made to accommodate the widest possible latitude of the characteristic in question. For example, a needed system gain control was located where it automatically compensated for the lot-to-lot variations of such a parameter.

Automatic Gain Control

Circuit functions were made independent of as many electrical factors as possible. For example, a fast-acting automatic gain control (AGC) arrangement was used both for the familiar purpose of making carrier-signal rectified output nearly independent of received signal level and to abstract a low percentage amplitude modulation from the carrier signal.

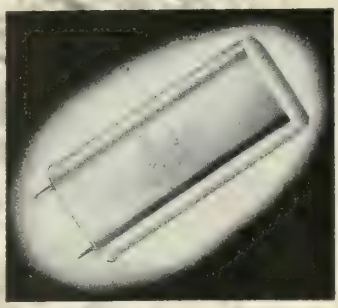
Early designs provided only one AGC loop. Unfortunately, a change of received signal level, though followed by a gain change that preserved the original carrier output, altered the amplitude of the abstracted modulation voltage on which system control sensitivity depended. An improved design provided separate AGC feedback paths for carrier and modulation frequencies, rendering control sensitivity independent of received signal level.

Adjustments and trim points were kept to a minimum. These features frequently reflect avoidable design imperfections. Components generally used as trimmers incline to be mechanically weak and to suffer wide electrical value drifts with aging.

All circuits were tested individually and early in simulations of their expected operating environments. Humidity effects were especially borne in mind. Breadboarded circuits were checked for humidity tolerance by subjection to steam and by temporary connection of shunt resistances similar in value to leakage resistances foreseen in printed circuits.

Tube application information was treated seriously. Control-grid biases were kept more negative than −1 volt. Operation at very low plate currents was avoided. Heater-to-cathode resistances were assumed no higher than 0.1 megohm. Electrode dissipations were kept within normal test-condition levels rather than within maximum ratings. Tube mountings were devised that kept envelope temperatures far below those specified in vendor's test conditions. Circuit designs allowed realistically for variation of tube parameters with heater voltage variations.

No major reliance was placed on tests using limit-value tubes, since these were long-delivery items when available at all. Rather, consultations were held with tube vendor applications engineers to learn the statistical probabilities of various departures from nominal tube-characteristic values, and then theoretical calculations and simulation of tube variations were relied on to show whether circuits would function with tubes exhibiting the expected statistical variations.



Wherever possible, circuits were operated at the highest signal levels allowed by component rating to enhance signal-to-noise ratios (noise here including dc drift, microphonics and hum, together with the commoner tube noises).

Moderate negative feedback was used often, with loop gains of 10 or 20 as a compromise between the benefits of feedback and an excessive component count.

Much attention was given to connectors and harnesses. Connectors were used that provided multiple spring-loaded current-carrying bearing points in each individual female contact. Also, connectors were chosen that included rugged shells to forestall pin and insulator damage on rough handling. Wires emerging from connectors were sealed to the shells with a rubber potting compound; flexure of cables leading to connectors was rigidly limited. All female contacts in connectors were individually checked at the vendor's factory by a pull test using a standard male pin. Wire harnesses assembled to

BULOVA

FAMED FOR PRECISION SINCE 1875

NEW ST-73X

"SHOCK MOUNTED" QUARTZ CRYSTAL

The Bulova ST-73X need never be babied. Effective new shock mounting and traditional Bulova manufacturing precision result in a rugged, extremely stable, frequency determining element for missiles, aircraft and other applications involving extreme environmental problems.

Where frequencies must be maintained with ultra-reliable stability under high shock and temperature conditions, you'll find no adequate substitute for Bulova quality.

THE ST-73X FEATURES: Frequency Range from 16 KC through 350 KC, with lower frequencies possible in holders of different configuration; Shock Tests of 100 G; Dynamic vibration tests met per MIL-T-5422, MIL-E-5272 and MIL-E-5400 without adverse results; Storage Temperatures over a range of −65°C. to +135°C. can be coupled with an operation temperature range of −55°C. to +100°C.; Low excursions of frequency (±.015%) over this range.

Precision Bulova Quartz Crystals are now available in quantity for frequencies from 16 KC and lower to 100 MC and above.

connectors were tested for high-voltage breakdown and for continuity by an automatic tester.

Space restrictions prohibited the use of point-support vibration isolators, and so low "Mechanical Q's" (vibration amplification factors) were imperative in all packages. Structures were made stiff with high natural resonant frequencies, experience until then having shown that this was the most practical way to realize low Q's. It should be said that more recent techniques incline rather toward the use of "lump" structures with layers of dissipative materials sandwiched into the structures to absorb vibratory energy.

The system's packages were to be mounted on a T-beam in the missile. An early mockup of this beam, loaded with dummy packages, disclosed a fundamental beam resonance at about 120 cps. Package internal resonances accordingly were kept well above 200 cps to avoid any risk that they might coincide with the beam resonance.

Much thought was given to heat flow. The primary problem was cooling during test, where the outside skin of the missile control served as the heat sink. The high temperature reached by the skin during flight was not of concern because the flight duration was small compared to the thermal time constant of the control.

Because of mechanical design requirements, metal heat-conducting paths to the outside skin were not possible. Instead, heat was transferred metallically from hot components (such as tube envelopes) to larger surfaces such as chassis or tube blocks, and normal air convection was then relied on to transfer heat from these "couplers" to the outside skin.

An early model of the control system that accurately represented the final model in heat transfer characteristics (but which included only preliminary circuitry) was built in order to evaluate the design. Thermocouples were embedded in first-sample potted assemblies ordered from vendors for use in this model. Tests showed that during the specified test cycle, the maximum temperature rise above outside ambient was only 45°C; many areas exhibited only a 35° rise.

Work to gain immunity to high humidity centered chiefly on improvements to printed circuit boards. Numbers of board materials and coatings were investigated, and conductor spacing was standardized at .062 inch. Even after an optimum selection of materials, however, electrical designers were obliged to observe certain restrictions rarely met in other wiring. Among others, circuit impedances exceeding 0.5 megohm required special

approval; guard circuits were required in many instances.

Establishment of a design does not end the reliability tasks. As engineering models are built, all designers responsible must perform or witness the evaluation tests, particularly environmental tests, analyze failures and make design corrections. Complete reporting and exhaustive analysis of all failures is the duty of the designers. The insight gained must "feed back" and culminate in design refinements for as long as the schedule permits.

Certain factory tolerances on parameters of subassemblies, assemblies or whole systems, are not predictable from component tolerances in any simple way. They must be assigned after direct measurements of the parameters of a number of subassemblies, etc., normally in late-engineering model systems when these and production models are expected to be nearly identical. (The route from measurements to tolerances is not recited here.) These assignments are of interest both to the reliability coordinator and to the quality control department.

Quality control must be arrived at or be furnished with tolerances early in a first production run in order to monitor manufacturing processes. The reliability coordinator and all designers of a system are concerned because the agreement of tolerances finally set is some measure of the perfection of a design. This process, in the case at hand, was notably successful. Of the hundreds of such tolerances most were set on the basis of 15 design-approval models, and less than 2 per cent were changed during the following pilot and production runs.

Sufficient Data

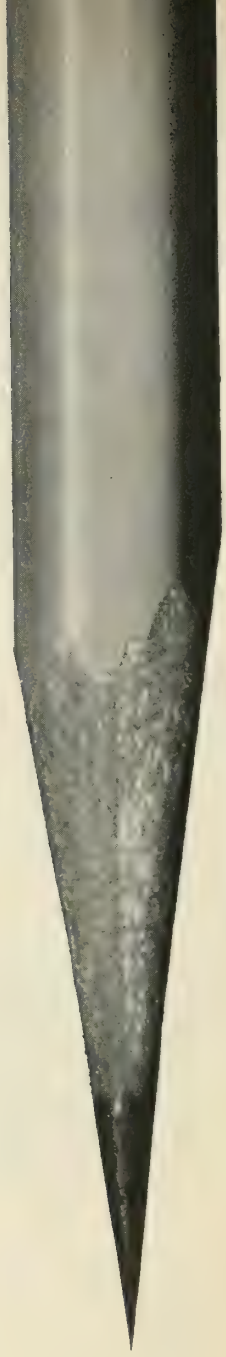
Sufficient data to establish the exact flight reliability of a missile control is not readily available and does not yet exist for the *Terrier* control. (However, as mentioned earlier, no reliability failures have been noted in design-approval flight tests.)

The emphasis placed on reliability at every phase of the re-engineering of the *Terrier* guidance control system has resulted in a marked improvement of system producibility and tactical effectiveness. The engineers "lived" reliability on this project, acknowledging its importance in the selection and application of components, in the choice of circuit designs, in the mechanical design approach and in the production support effort. The techniques were simple but required constant emphasis. The application of statistics to electronic design was new to most of the engineers when they started but became second nature before they were through.★

COMMAND SIGNAL GENERATOR — COMMAND SIGNAL RECEIVER — SYNCHRO POSITIONER — AUTO PILOT CONTROL

STEPPER
SYNCHRO POSITIONER

Accuracy: Within 6 min. of arc when driven by either motor.



Incremental shaft rotation: 2 degrees.

This is one of the many applications for the Stepper Motor — a device for translating electrical pulses into accurate, bi-directional, incremental shaft displacements.

The Synchro Positioner uses two Stepping Motors, an Autosyn differential, and a built-in pulse generator. One motor positions the Autosyn Shaft in coarse increments in either direction, while the other motor, using a different gear ratio, positions the same shaft in vernier increments in either direction. As the reset command signal is of steady-state type, the built-in pulse generator permits use of the driving motors for the reset function.

training potentialities of synthetic missiles

Missile management is recognizing the need for training priority and budgetary support

by J. Gordon Vaeth and
Lt. Cmdr. John Huson, USNR
U.S. Naval Training Device Center

MISSILEMEN in both government and industry increasingly are recognizing the importance of training to the effectiveness of weapons now in development or production.

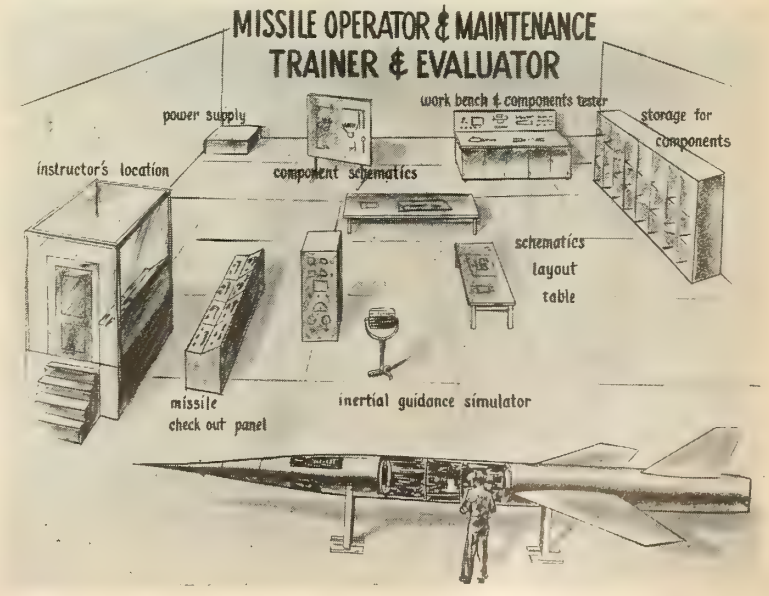
Regardless of the development and refinement which go into it, a missile is still at the mercy of the men who handle, assemble, checkout, "troubleshoot," fuel, fire and, perhaps, control it. As such, its reliability and performance are subject to human failings and errors.

And whereas ordnance personnel mistakes with weapons of pre-atomic days might have been destructive and tragic, when made with nuclear arms they can be globally catastrophic.

A new concept in missile engineering—a concept intended to reduce or eliminate training degradation of costly and short-supply missiles—has recently been advanced by training specialists of the U.S. Naval Training Device Center, Port Washington, N. Y. It emphasizes maximum and, if possible, total use of synthetic equipment.

Industry is beginning to see training as a critical, yet often overlooked, factor which is essential if a stockpiled missile is to become a live and effective weapon of defense or offense. Missile management is aware that training requirements must form an integral part of any weapon system, if that system is to be complete or effective; long-range planners are giving training considerations priority attention and budgetary support as never before.

Yet even when training problems are correctly anticipated, the solutions are usually stereotyped. The usual procedure is to establish a service school for instruction on the weapons and to divert a number of operational missiles from the production line to be used for this purpose.



Operational missiles, however, are not designed, engineered or intended to undergo continual classroom disassembly and reassembly by inexperienced trainees. As a result components soon wear out. The missile is rapidly degraded until finally it has to be scrapped or completely overhauled at a cost approximating the price tag of a new missile itself.

Experience has shown that complex operational missiles are good for about three months of classroom usage; then they must be replaced. Experience has also proven that long before the missile reaches the "replace" stage, it is heavily subject to "down time" which can seriously disrupt orderly scheduling of classes and efficient instruction.

Formal school training with operational missiles suffers from still another disadvantage. Using production-line hardware, it is difficult for instructors to illustrate any variety of controlled malfunctions. Since the best way to evaluate a missileman's competence is to give him a number of different type troubles and check his ability to detect, isolate and remedy them, this means that technical training on operational equipment is, without considerable modification of that equipment, only partly adequate at best.

The concept evolved by the Office of Naval Research's NAVTRADEVCEN seeks to overcome these difficulties. It proposes to do so by substituting synthetic equipment for operational gear wherever possible.

Cornerstone of this new concept is a full-size dummy missile. Every component of the operational bird vis-

Circle No. 126 on Subscriber Service Card.

ible or accessible to maintenance men or to firing crew members is reproduced to exact size and appearance. Access hatches and check points are realistically duplicated. The dummy is a detailed "live" mockup.

Systems and components which launching, operator or maintenance personnel have to check, adjust, repair or replace on the actual missile, are synthetically activated by simulation techniques. The black boxes are all there, their inputs and outputs reading the same on the missile test equipment as if they were operating in the genuine weapon itself. Yet the boxes are dummies, activated to give correct responses by straight electrical, rather than electronic, simulation means.

The dummy, with its synthetically "live" components, is connected to the appropriate missile checkout or fire-control panels. These, too, are synthetic and duplicates of the actual panels in every external or visible detail. They provide the correct light and meter indications as dictated by the "condition" of the dummy missile. This "condition" is controlled by an instructor who can introduce from his console a variety and number of typical malfunctions. He must determine how quickly and accurately the trainees can spot and repair the troubles. If component replacement is required the dummy offers the same difficulty of access as does the real missile. The time it takes for the malfunction to be remedied and the actions taken by the trainees are automatically recorded for post-exercise critiques.

The national economy cannot long endure the wholesale degrading, wearing out and expending of costly, complex missiles for strictly routine training purposes. Less costly ways must be found, although it is recognized that a certain number of proficiency or "confidence" firings will always be required.

New simulation techniques and synthetic equipment can provide these ways. Missile fire-control radars can be activated and moving targets synthetically generated on their scopes. And by using the latest in the simulation engineer's bag of tricks, the missile itself can now be synthesized—for formal technical training, for the exercising of firing crews, and for evaluating the readiness and ability of Army, Navy, Marine Corps, and Air Force units to checkout, troubleshoot, and launch the missiles which industry is placing at their disposal.★

space communications tested with X-17

By Henry P. Steier

COMMUNICATIONS between space ships or missiles and earth probably will not pose too much difficulty once they are free of the earth's atmosphere. It is in the region between sea level and a few hundred miles altitude, which contains gases, that radio transmission difficulties occur.

These transmission problems are associated with aerodynamic heating. The shock wave that exists around the nose cone of a hypersonic missile causes intense heating of the air round it.

Between the shock wave and the missile surface is a shock layer in which "aeromolecular" effects occur. These are induced by the high temperature. Among these effects is production of free electrons. This causes communication interference.

Very little has been revealed about findings thus far collected on radio transmissions from hypersonic missile tests. Probably some of the most significant information about the problem has been collected by Lockheed Aircraft Corp.'s Missile Systems Division.

About a dozen flights were made by Lockheed's X-17 re-entry test vehicle. Much information about what happens to radio signals in flights from sea level to about 100 miles altitude is believed to have been collected.

The radio information was, of course, relative to re-entry phenomena in connection with nose-cone research. However, some of the vehicles were fired specifically to develop telemetry systems suitable for the X-17 flight environment.

Tight Military Security

Some time ago, Lockheed engineer N. Turveen admitted (m/r, April 1957) his company had experienced "a peculiar phenomena observed in the variation of radio frequency field strength under X-17 flight conditions."

Beyond that, he said, military security was tight-lipped on exactly what happened. However, the company is continuing its studies in this problem area, as evidenced by recent announcement of a Lockheed Space Communications Laboratory.

The new facilitiy located at Sunnyvale, Calif., is a three-story, 10,000-sq.-ft. building in which space conditions as they exist hundreds of miles above the earth can be re-created.

According to the company, antenna design and installation for the Navy's *Polaris* ballistic missile are among the projects being studied in the new laboratory.

In a recent report on missile aerophysics phenomena of electronic import, Lockheed engineer Daniel Bershader discussed some of the features of environment surrounding missile-type vehicles in hypersonic flight.

On a theoretical basis, Bershader said, effect of ionization of the compressed and sheared air of a boundary layer around a vehicle on transmission of microwaves can only be calculated approximately.

The boundary layer is an area around a missile which exhibits a velocity profile of air extending from zero to near-free-stream value of air around a vehicle. Air is brought to rest by impact with a nose cone. The kinetic energy is transferred to thermal energy.

At Mach 22, at 150,000 feet altitude, the temperature created would be 13,000°F. From the highest boundary-layer temperature point on the nose cone to points along the afterbody of a missile, the temperature profile changes.

At about 2,200°F, which corresponds to a stagnation, (or zero air molecule velocity condition) for Mach 6, energy balances in gases composing air come into play. Near Mach 10 oxygen disassociates. Chemical reactions occur. Nitric oxide is among the formations produced.

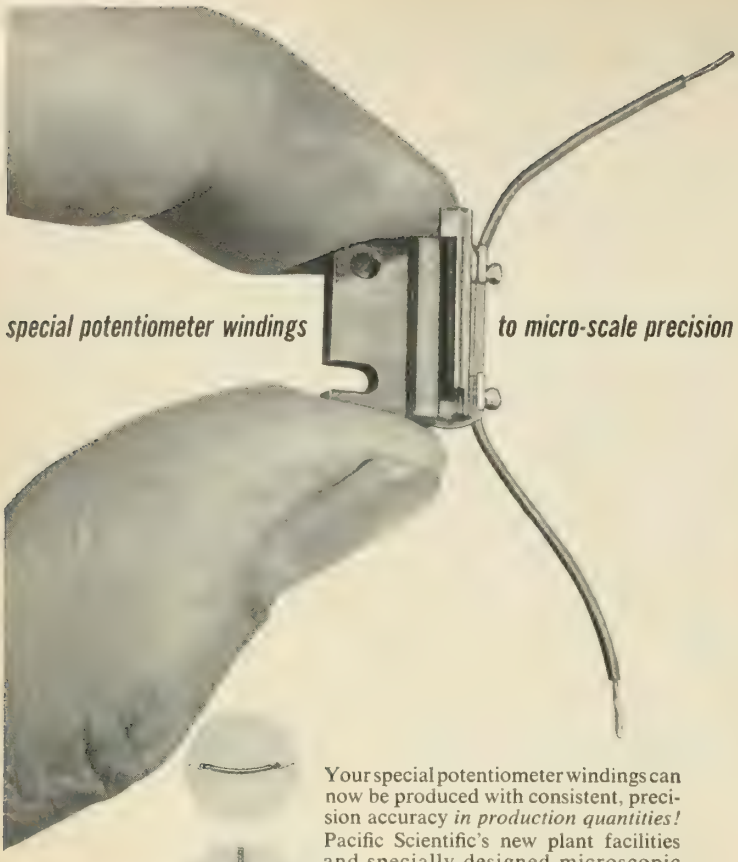
Disassociation of nitrogen starts at about 10,000°F, corresponding to a stagnation temperature for Mach 17, and at this point ionization becomes significant.

Heat and Light Produced

At the higher Mach numbers much of the energy released goes into atomic-molecular processes. These are dynamic and accompanied by recombination and de-excitation phenomena. Heat and light are produced. This occurs at certain rates depending upon

Unsurpassed for accuracy and dependability, Whittaker Gyros are able to shrug off the effects of shock, acceleration, vibration, heat or cold.

THE REASON? For all the foregoing conditions, Whittaker Gyros have been *100% tested!* Rigid quality control has resulted in continued customer satisfaction since 1946.



And because Whittaker uses nickel alloys such as a monel for frames and gimbals, added strength is gained with little increase in weight.

Whittaker engineers and technicians have worked together as a team for more than a decade. This background and experience insures meeting exact specifications the *first* time.

boundary-layer temperature profiles. The reactions, however, require time, since there is a mean-free-time between particle collisions in a gas.

Meanwhile, the surface layer of a hypersonic vehicle is inhabited by free charges of ions and electrons. It is these, Bershader said, that one would expect to effect the radiation pattern of a transmitting antenna on a vehicle body. Also, the impedance match between antenna and atmosphere would be affected by the local environment.

In considering theoretical solutions to this problem, the parameters would be electron concentration distribution, which controls the attenuating path length; frequency of transmitter, reflection and refraction, and electron collision frequency.

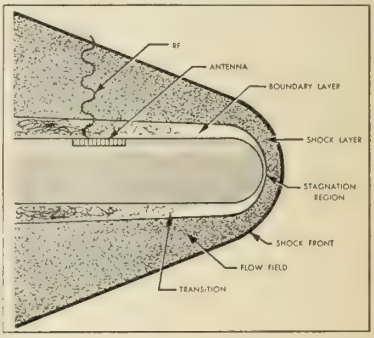

Diagram showing complex environment around a blunt-nosed vehicle at hypersonic speed. Transmission of RF energy through boundary-layer region of atomic-molecular process activity poses frequency dependent problems.

The relationship between transmission frequency and the effect depends upon the "plasma" frequency, which in turn is a functon of electronic charge and mass.

Although the determination of attenuation factor can be approached mathematically, much more information is needed on what goes on in a hypersonic vehicle's surface layer. It is known that at velocities of about 20,000 ft./sec., ionization of sheared and compressed air of the boundary layer yields a conductivity equivalent to that of fused sodium chloride, Bershader said.

The loss of radio energy in db per inch is directly proportional to a complex propagation constant for wave passage through the ionized medium.

To minimize the attenuation, it was noted, it is necessary to make the transmitting frequency "appreciably larger than the characteristic plasma frequency of the boundary layer."

Recently it has been reported that attempts are being made to use ionization trails from aircraft and missiles as low-frequency antennas. In this case high electrical conductivity of the ionized paths is used for coupling. ★

NEW MISSILE PRODUCTS

TELEMETERING DIPLEXER

Hycon Eastern, Inc. has introduced a high-power telemetering diplexer, type 1231. The instrument feeds signals from 2- to 100-watt transmitters into a single antenna system and is designed to satisfy military requirements for use in test missiles and telemetering.

Environmental specifications are: shock to 100 g, vibration to 200 g at 2000 cycles, temperature —70°F to 350°F. Units made of Invar may be provided at

extra cost for use up to 500°F.

Other specifications include frequency range: fixed-tuned between 215 to 250 mc/s; isolation: 28 db with 10-mc separation, 25 db with 6-mc separation; attenuation: less than 0.3 db; power-handling capacity: rated at 100 watts cw, size: each cavity approximately 3"x4"; weight of total system: 3.7 lbs, pressurization: diplexer cavities are filled with dry air and permanently sealed.

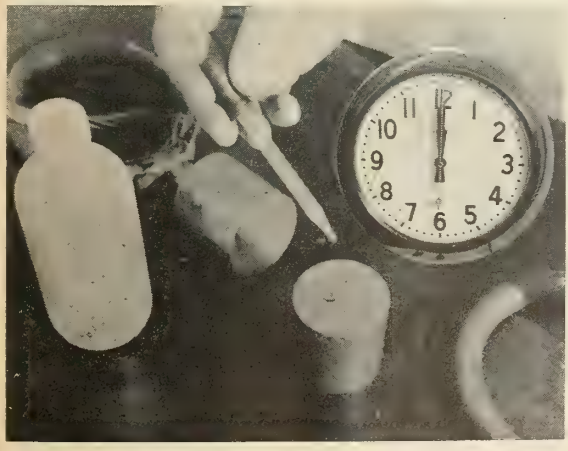
SOLID STATE BATTERY

The Patterson, Moos Division of Universal Winding Co. has developed a miniature, high voltage, solid-state battery that is capable of delivering high current drains for long periods of time.

Called the "Dynox 95," the first model of the new battery is 1¼" long, ⅜" in diameter, and has a potential of 95 volts in 0.14 cubic inch. It can supply a steady current of $1x10^{-9}$ amperes for 176,000 hours at 70°F with only a 10% voltage drop, or a flash current of 20 microamperes. It can be stored for 20 years without losing its power. Other characteristics include resistance to extreme shock or vibration, performance at extreme temperature ranges, including the ability to operate after temperature cycling between —100 and 170°F.

Circle No. 211 on Subscriber Service Card.

MONITORSCOPE



Applied Science Corporation of Princeton has developed an electronic tool enabling engineers to test 86 test point variables at a glance. The instrument may be used for flight instrumentation, production-line testing and for monitoring. Test data can be observed as a varying line display on an oscilloscope screen, while individual data samples are presented in bar-graph form. The device is available for field or laboratory use.

PORTABLE POTENTIOMETER

A new type portable potentiometer featuring interchangeable scales, and automatic compensation has been introduced by Technique Associates, Inc.

ADHESIVE LIFTS 5000 POUNDS AFTER 30-MINUTE SET

Eastman Chemical Products, Inc. has developed a new adhesive with rapid-set characteristics and capable of bonding a wide range of materials. Designated Eastman 910, the new material is shown supporting over 5000 lbs. after one drop of it was placed between two pieces of steel rod 30 minutes previously. The adhesive requires no heat, pressure, evaporation of solvent, or long curing time. It bonds wood, metals, glass, ceramics, rubber, plastics, porcelain and other materials. Eastman 910 has proven valuable in joining small intricate assemblies and is in limited production at the company's laboratory.

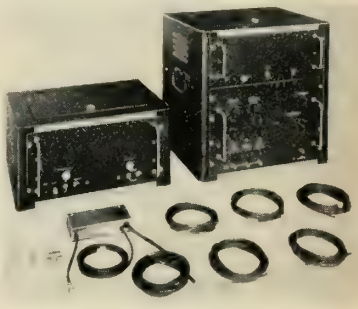
Interchangeable scales permit measurements of a wider range of temperatures and voltages.



Known as the Thermotest-I, the instrument is an all-purpose testing device for making highly accurate temperature measurements from −200°F up to 600°F. Ordinary thermocouples are used. The instrument will also measure voltages from zero up to 21 millivolts. Scales which are calibrated in degrees centrigrade are also available.

Circle No. 208 on Subscriber Service Card.

RADAR INTERFERENCE BLANKER

A radar interference blanker, Model RB-128, which eliminates "main bang" interference in a group of normal and MTI radar sets, or reduces it to a negligible value, has been developed by Empire Devices Products Corp.

In operation, the interfering signal is bracketed with a negative blanking gate to eliminate it from the protected radar's display. Since the PRR of the protected radar and that of the interfering radar are usually not synchronized, any loss

of displayed information is unimportant.

The RB-128 blanker system is self-contained; no additional transmitters, receivers, telephone lines or coaxial cables are required, irrespective of the number of interfering radars. Distance from the offended radar is not a factor, so interference from shipboard or airborne radars is also eliminated.

The blanker may be added to existing radar installations without appreciable modification of operating equipment. The use of instantaneous automatic gain control circuits and very low time constants in grid circuits reduces the guard-band receiver's susceptibility to jamming well below that of the radar being protected.

HELIUM DEWAR

Information is now available on design of Hofman Laboratory's new solenoid dewar flask for the study of the effects of magnetic fields on various properties of solids at liquid helium temperatures in the laboratory.

Circle No. 217 on Subscriber Service Card.

ACTUATOR MOTOR

Viking Tool and Machine Corp. has developed an actuator motor featuring high starting-torque that is suited for remote control switching, homing devices, valve operation and other applications. It operates at temperatures up to 500°F at 60 cycles ac, or 400 cycles ac as well as pulsating dc.

The motor is basically a compact, lightweight ac rotary solenoid with a vibrating rate of 120 cycles/second when

operated on 60 cycle ac. This rapid vibratory motion is translated into rotary stepping motion through a fast-acting one-way clutch.

The company says the device features higher torque for its size and input power than normal solenoids since it is always vibrating within the most efficient portion of a solenoid's stroke and does not have a relatively low torque initial pull-in. The device operates at moderate speed and at either 60 cylces or 400 cycles will operate at free speeds of less than 300 rpm.

Circle No. 209 on Subscriber Service Card.

CRYOGENIC PUMP

Sundstrand-Denver has developed a compact, lightweight, piston-type pump suitable for pumping liquefied gases such as nitrogen and oxygen. The pump has the capability of pumping liquid nitrogen at pressures of over 3000 psi at speeds of over 3500 rpm. Sustained operating periods of over one hour have been obtained repeatedly without any form of lubrication. The performance data for the pump are: capacity @3500 rpm, 1.75 gpm; horsepower @3500 rpm, 3.8 hp; weight 2.5 lbs.

The pump has nine axial pistons and is of the fixed displacement type. Metal parts have been selected to be compatible with liquid nitrogen. Minor material changes can be incorporated to permit satisfactory operation using liquid oxygen. Since this pump is a modification of a standard Sundstrand hydraulic motor, larger capacity pumps can be provided with relatively little development.

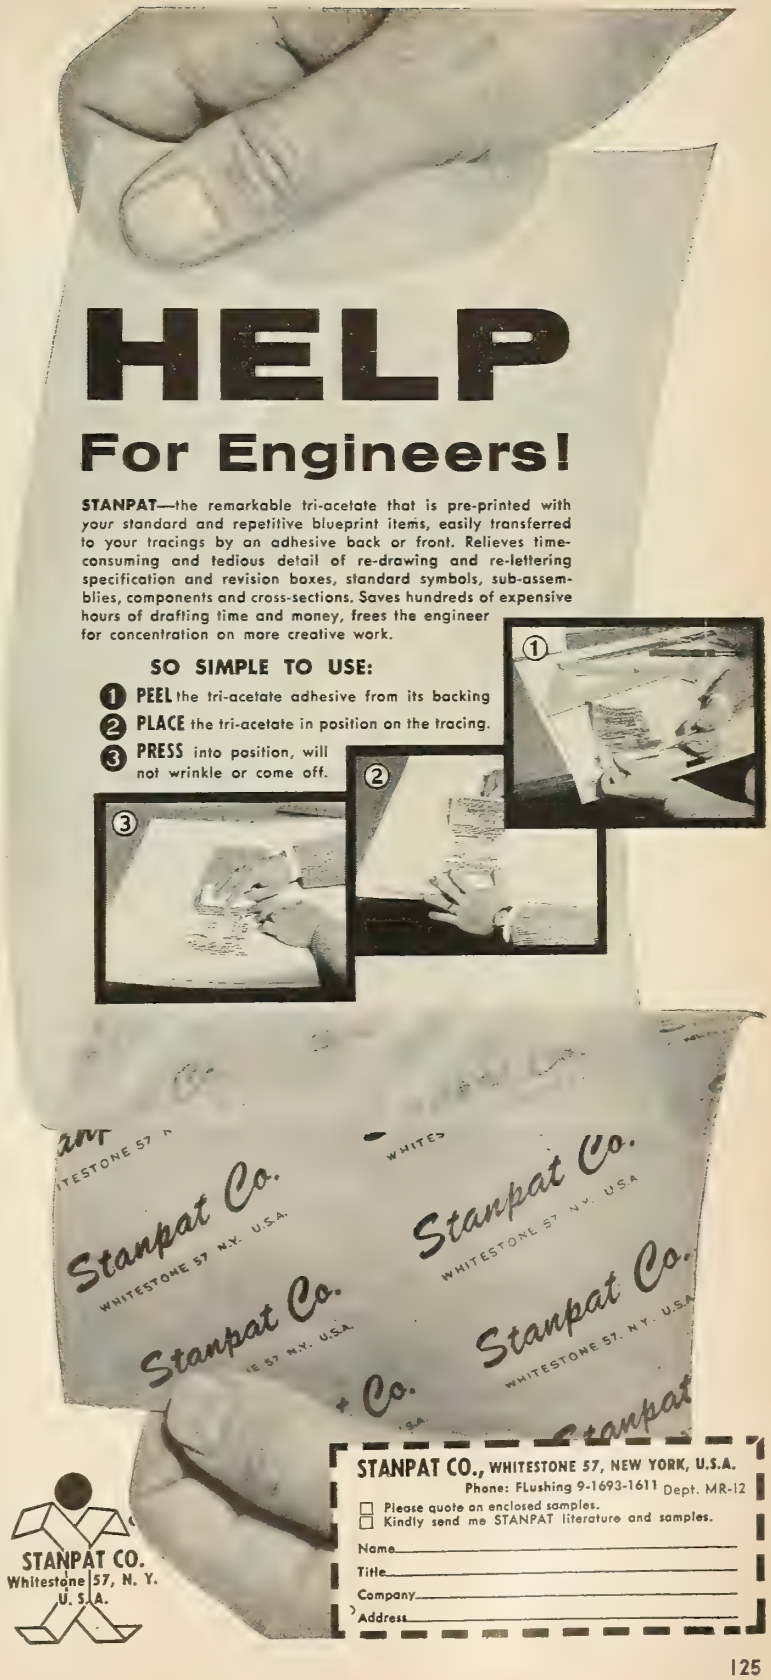
Circle No. 210 on Subscriber Service Card.

IGNITOR DEVICE

Electronic Specialty Co. has introduced a new product to check the ignition and squib circuits in guided missiles and rockets. Designed to be more effective than previous methods of testing these circuits, the device takes the current for the normal time and then breaks the circuit just as an ignitor or squib would. The unit can be used for thousands of test firings.

An additional feature is the indicator arrangement. A small translucent button pops out to show that the firing circuit has operated. A mechanical reset makes the device ready for the next test immediately after firing with no part replacement. The device is available in a variety of maximum current ratings and operating time characteristics. Because of the nature of simulation and test devices, the units are produced to customer requirements.

Circle No. 204 on Subscriber Service Card.



PITCH-YAW INDICATOR

Edcliff Instruments now has its Pitch-Yaw Indicator in full production. The free-swiveling aerodynamic head provides potentiometer output linear with angles of pitch and yaw.

High-temperature components used throughout the instrument permit operation at high Mach numbers. The Model 4-1 is available in ranges up to 27½°, with an indicating accuracy of 0.1°. Overall length is 4".

Metering is provided by two precision wire-wound potentiometers with single-wire function taps. Static or total head probes are available, either singly or combined.

new ELECTRO SNAP ROCKET SAFETY SWITCH

Sketch shows typical switch and rocket tube application. Rocket switch controls various indicator, sequence and other electrical circuits. Several models now in production. Send us your design requirements.

...from the makers of the leading line

of HERMETICALLY SEALED LIMIT SWITCHES

Electro-Snap has developed a complete line of hermetically sealed limit switches to bring the ultimate in environment-free switching to aircraft control circuits. With a record of dependability totaling millions of hours, Electro-Snap Hermetically-Sealed Switches have been used as original equipment by major aircraft producers—on standard and experimental aircraft for both commercial and military use. They are also being widely used for retro-fitting, to modernize existing control circuits for the more exacting demands imposed on today's aircraft. If aircraft switching is your responsibility, you should know about this modern line of switches for modern aircraft. Write for specifications.

To meet modern aircraft requirements, Electro-Snap has developed and perfected this, the first truly hermetically sealed rocket switch. Because both the basic switch and the operating mechanism are sealed in an inert gas, the switch is unaffected by extreme heat, or cold, humidity, water, oil or temperature cycling. Tipping action of the actuator prevents jamming by ice. Completely environment-free, the dependability of the switch and its operating action have been thoroughly proved on today's newest fighter aircraft.

IMPORTANT CHARACTERISTICS

Contact Arrangement	SPDT, 1 circuit
Capacity	4 amps. resistive, 2.5 amps. inductive at 30v DC.
Electrical and Mechanical Life	150,000 operations min.
Vibration and shock resistance	Excellent

Missile Business

by Seabrook Hull

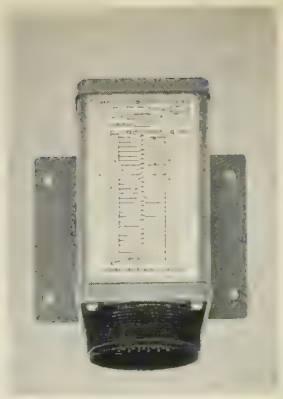
NOTHING COHERENT will be done about the U.S. missile program before the start of the new year. Between January 1 and February 1, 1958, these things will happen: Congress will return; the President's Budget and State of the Union Messages will be presented to Congress; tax payments January first will begin to swell the Treasury's cash balance. Until all of these things are done, little is possible in the way of reorganization of the U.S. missile program.

One exception, of course, is that Congress can and will start its investigations earlier. Lyndon Johnson's Senate Preparedness Subcommittee held five days of hearings starting November 25. Witnesses from both inside and outside the Government were heard. Johnson wants to have a report ready for Congress when it reconvenes.

UNSPECIFIC THOUGH THEY WERE, the President's security and science talks do give a pretty clear indication of Administration thinking in some of the more costly defense areas. For example: No plans to kill off Strategic Air Command any time soon; means more planes will be bought; SAC bases further dispersed. Also, SAGE is relatively worthless (some experts say completely worthless) for in-time interception of large ballistic missiles; means more and better early warning gear. Anti-missile missile: Both Army and Air Force projects will be pushed. The President, in talking about future missile spending, pointed out that we are now spending "more than $1 billion" on missile research and testing. Production, deployment and installation of the birds, particularly the big ones, will really run costs up. For example, ICBMs will certainly be deployed underground; IRBMs, probably. These installations will require extensive facilities.

PAYMENTS HAVE BEEN LIMITED to 80 per cent on cost-reimbursement contracts, according to an order of Defense Secretary McElroy. The other 20 per cent contractors will be expected to put up out of their own working capital or borrowed funds. Cost of using their own money for working capital will be taken into account in costing the contracts. Meanwhile, the Air Force (but not Army and Navy—yet) will attempt to rewrite some $250 million in cost-reimbursement contracts now outstanding. They will be made to conform to the 80 per cent provision.

This device will limit cash outlays now, and thus help the budget. But the Government must pay sometime; means things will be tougher at the end of the contract when final settlements are made.



BASIC RESEARCH WILL GET ANOTHER BOOST IN FUNDS. This is being ordered by Defense Secretary McElroy in another move reversing the trend begun by his predecessor, Mr. Wilson. Not only are more funds being voted, but an effort will be made to institute management practices to encourage a greater amount of basic research.

DON'T BELIEVE ADMINISTRATION ASSURANCES that no substantial increase in missile spending will be necessary. It's virtually certain that the President will ask to have the statutory debt ceiling raised. It's also virtually certain that before the current fiscal year is out the Pentagon's missile and space-flight program will be overplanned rather than underestimated. The administration cannot risk another setback such as that incurred with the *Sputniki*. And some of these programs will be greatly accelerated in order to quickly achieve a major space flight "first" ahead of Russia.

NEW LOW-NOISE CHOPPER

Bristol's Syncroverter† chopper is now available in a low-noise, external-coil model for critical dry circuit applications.

This new external-coil chopper virtually eliminates capacitive coupling between signal-circuit contacts and driving coil leads. Peak-to-peak noise levels are usually *less than 100 microvolts* across a 1 megohm impedance (rms noise, in the order of 10 microvolts).

LONG LIFE and immunity to severe shock and vibration are outstanding characteristics of the new Syncroverter chopper. Withstands vibration, 5 to 2000 cps, up to 30G, and up to five 30G impacts on any major axis. SPDT switch action. Nominal contact ratings: up to 10 V, 1 ma.

Write for complete data on this latest addition to the Bristol Syncroverter line. The Bristol Company, 173 Bristol Road, Waterbury 20, Conn. 7.31

†T. M. Reg. U. S. Pat. Off.

TYPICAL CHARACTERISTICS

Driving Frequency Range:	0—1800 cps
Coil Voltage:	6.3 V sine, square, pulse wave
***Coil Current:**	70 milliamperes
Coil Resistance:	52 ohms
***Phase Lag:**	60° ± 10°
***Dissymmetry:**	15° max.
***Switching Time:**	15° ± 5°
Temperature Ranges:	—55°C to 100°C or —65°C to 125°C
Operating Position:	Any
Mounting:	Flange; 2-hole or 4-hole Plug-in; fits 7-pin miniature socket

*These characteristics based on sine-wave excitation, 400 cps.

SCIENTISTS AND ENGINEERS:

Lockheed Missile Systems offers staff positions at Palo Alto and Sunnyvale, California

(Both facilities are within 38 miles of San Francisco)

Weapon systems management programs at Lockheed Missile Systems call for achievement of a high order in these fields. Assignments are on the Polaris Intermediate Range Ballistic Missile program and other extremely important activities.

Aerodynamics

Theoretical and experimental investigations of the aerodynamic characteristics of missiles at Mach numbers through the hypersonic range; optimization of controlled missile performance; specification and supervision of experimental aerodynamic investigations required to verify and improve missile and weapon system design; analysis and interpretation of aerodynamic flight test data.

Flight Dynamics

Analysis of missile dynamic motion and establishment of stability and control systems criteria for trajectories with 3 or more degrees of freedom; development of techniques for the analysis and interpretation of flight dynamics test data at hypersonic speeds; study of special dynamics problems arising during preliminary design and development of missile systems.

Thermodynamics

Boundary layer and heat transfer analysis in hypersonic flow fields such as pressure gradient- and real-gas effects; analysis of thermodynamic performance of missiles in continuum flow, slip flow and free-molecular flow; calculation of transient structural and equipment temperatures resulting from aerodynamic heating and radiation; specification of ground tests and flight tests required to verify and improve thermodynamic design of missile and weapon systems; analysis and interpretation of thermodynamic ground test and flight test data.

Engineers and scientists are invited to address inquiries to: Research and Development Staff, Sunnyvale 7, California.

INSPECTION PROBLEMS?

This booklet is for you!

This comprehensive, elaborately illustrated booklet provides practical information on the use of the famous A. C. M. I. Borescope in various industries, for the inspection of interior areas or surfaces not otherwise visible—together with full data on the types of Borescope available, and on their care and maintenance. Have you received your copy?

Free on request — *Fill in and mail today*

To *American Cystoscope Makers, Inc.*

Bomarc Switches to Solid Rocket Booster

An advanced model of the *Bomarc* surface-to-air missile will employ a solid-propellant rocket booster (m/r Sept., p. 164). Present IM-99, recently ordered into production, is boosted to altitude and ramjet-engine velocity by an Aerojet liquid-propellant engine.

The switch to the solid-propellent system will improve logistics and provide a possible increase in range, altitude and velocity. The liquid system now used forms the major portions of the missile's weight and volume. It cannot be cropped after burnout, a feature which undoubtedly imposes performance limitations that would not be present with a droppable solid-propellant booster system.

Northrop Missileers Report for AF Duty

Twelve missile specialists from Northrop Aircraft's customer field service section have reported for duty with 6555th Guided Missile Squadron at Patrick AFB to assist in training of the Strategic Air Command for *Snark* SM-62A operations.

The proficiency training team, whose members have undergone a rigorous training program over the past months, is headed by Jim McFarlane. McFarlane formerly was an engineering assistant on *Snark* guidance tests and later worked as guidance test engineer during launching tests at Cape Canaveral.

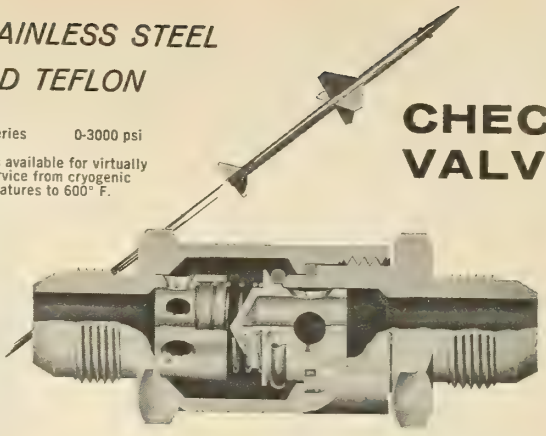
Additional Helium Production Requested

The Interior Department feels that increased missile needs warrant the construction of an additional helium-producing plant. The plant, costing $14 million, would increase output by about 240-million cubic feet.

The government now has four plants producing about 365 million cubic feet annually. Present missile systems use an extensive volume of the gas for propellant pressurizing systems.

Thiokol Motors Score 97.5% Reliability

Flight performance records for large solid-rocket motors, powering missiles approaching the IRBM and ICBM class and developed and manufactured by Thiokol, have achieved a 97.5 per cent reliability record.



Thiokol first broke the "size barrier" for large solid-propellant motors with its successful engine for General

Indispensable

AIRCRAFT YEAR BOOK FOR 1957-58

Official Annual of the Aircraft Industries Association of America

FEATURING

- Photographs, specifications, and drawings of planes, engines, and missiles now in production.
- A survey of aviation activities in the Army, Navy, Air Force, and other government departments and agencies.
- A summary of aircraft company and airline operations during 1957.
- A digest of current aircraft and missile research progress.
- A pictorial review of outstanding aviation events of the past year.
- A chronology of American aviation history from its early beginnings to the present day.

THE 1957-58 EDITION OFFERS MORE to its readers than ever before. *Completely redesigned* throughout, the book will be filled with more valuable information, more illustrations, more diagrams, more of everything than in any other issue in the thirty-nine years that *Aircraft Year Book* has served as the aircraft industry's own official record of its activities and accomplishments.

AVIATION'S STANDARD REFERENCE for nearly four decades, *Aircraft Year Book* is now edited and produced by American Aviation Publications, the world's largest aviation publisher. The new 1957-58 edition, encompassing the most complete review of American aviation ever assembled, will be off-press and available in January, 1958.

Please reserve in my name . . . . copies of the new

OFF PRESS IN JANUARY

Electric's RV-A-10. To date, 130 engines developed in this general size, or larger, have been fired. Ninety static tests were completely successful. In forty actual flight tests, only one missile failure was partially attributed to the rocket engine.

The missile most extensively proven in flight tests has been the huge 3-stage Lockheed X-17 developed for the Air Force as a test rocket for its ICBM program.

SENIOR RESEARCH SCIENTIST

INTERIOR BALLISTICS

A challenging position now exists at Aerojet-General Corporation for a man of broad, fundamental background capable of original experimental and theoretical studies. The complex interrelations of mathematics, physics, and chemistry as applied to the interior ballistics of rockets offer challenging problems to the creative research man.

The application of unsteady-state theory to ignition of propellant and to the study of temperature-resistant materials is typical of the problems encountered. Combustion of solid propellants, the rheological behavior of solid propellants in complex grain configuration, and the gas flow and heat transfer in nozzles are related important fields for research.

Particularly important is the ability to formulate experiments for the verification of theoretical calculations, devise the necessary equipment, conduct the experiments, and analyze the data using the most advanced techniques, including digital and analogue computers.

For further details on this interesting position in an ideal Western climate,

write: Dr. James H. Wiegand, Head, Interior Ballistics Research Dept.

Curtiss-Wright Expands Missile Effort

Curtiss-Wright Corp.'s latest acquisition in the missile field is the H. A. Wagner Co. of 14707 Keswick St., Van Nuys, Calif. It will operate the company as a wholly-owned subsidiary of its Aerophysics Development Corp. Latter is located at Santa Barbara, Calif.

FMC Corp. Develops *Hawk* Loader Vehicle

The completion of design and development of a new lightweight, self-propelled track vehicle for the *Hawk* loader, the first mobile missile handling unit of its kind, is the latest achievement of the ordnance division of Food Machinery and Chemical Corp.

The track vehicle was built for Northrop Aircraft, Inc., by FMC as part of the U.S. Army's *Hawk* surface-to-air missile system. FMC produced the track vehicle under contract to Northrop.

Aerophysics Awarded *Dart* Missile Contract

An additional contract, totaling $826,963, has been received by Aerophysics Development, Santa Barbara, Calif., for continued development of the *Dart* antitank missile.

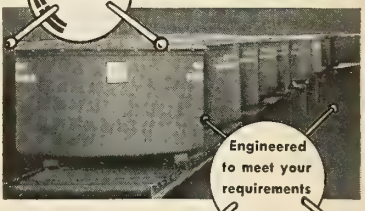
Operational status of the *Dart* has not been officially announced. Development is by Aerophysics with production by Utica-Bend Corp. (subsidiary of Studebaker-Packard).

Marquardt Test Facility Under Way

Marquardt's Ogden, Utah, facilities, which started delivering production ramjet engines for the *Bomarc* missile over two months ago (m/r Sept. '57, p. 168), has broken ground at the site of its ramjet-engine test facility. The test facility will operate in conjunction with the production plant.

Marquardt now holds a total contract award of $30 million for its Ogden plant.

Mack Trucks, Inc. Forms Electronics Division



The electronic research and manufacturing facilities of Mack Trucks, Inc., are being formed into a single division. Called the Mack electronics division, it will permit greater coordination of effort in the rocket, missile and aircraft fields.

ORDNANCE

The design, development and testing of advanced ordnance products and systems is one of the principal activities of the Research and Development group at Rheem Aircraft Division. The technical capabilities of Rheem in this field are evident in the extensive list of projects currently being conducted for the military and their suppliers:

- MISSILE WARHEAD SYSTEMS
- FUZING
- EXPLOSIVE ORDNANCE TESTING
- MINES
- GRENADES
- PRACTICE BOMBS

Rheem Ordnance Engineering is prepared to conduct complete programs in the field of ordnance systems including:

- *concept*
- *systems analysis*
- *development & testing*
- *prototype*
- *production engineering*

Ordnance research and engineering is complemented by the production facilities of the Aircraft Division of Rheem Manufacturing. Numerous ordnance products and systems are currently in production.

The Rheem developed Super Nike warhead system being tested on rocket sled built by Rheem.

Engineers: join Rheem in challenging technical work!

flexing a million-pound muscle...

Future achievements in the field of rocket propulsion depend upon the ability to test prototype engines at rapidly increasing power levels. To keep pace with these higher power requirements, RMI is completing work on a giant rocket test stand.

The new RMI test structure is capable of testing rocket engines in the million-pound thrust class. Its massive rotating system provides firing attitudes from vertically downward to 45 degrees above horizontal. The control center contains a maze of instruments that continuously record separate events occurring, within the engine, at intervals ranging from one-tenth of a second to less than one millisecond . . . and with accuracies up to ninety-nine per cent.

This addition to RMI's already-extensive test facilities paves the way for tomorrow's more powerful and more efficient rocket powerplants. It's another example of how RMI — America's *first* rocket family—is continuing to pioneer in the development and production of new engines for supersonic manned aircraft . . . helicopters, catapults and test sleds . . . and missiles for defense and space exploration.

Engineers, Scientists — Perhaps there's a place for *your* talents in RMI's expanding organization. Our new projects present challenging problems and the chance for greater responsibility.
